

SOA, ROA and the Semantic Web

How the Common Terminology
Services (CTS₂) Packages Ontology for
Service Oriented and RESTful
Architecture

Outline

Terminology Services – what is it and why do we care?

Common Terminology Services – quick background

CTS2 – PIMs, SOA, ROA and RDF

“Terminology”

A generic “term” that covers a broad spectrum of resources:

- Code / value pairs – Country codes, airline codes, fare codes, ...
- Controlled vocabularies – when United Airlines uses “confirmed reservation”, they mean “...”
- Thesauri – If you are looking for information on the Tiger Swallowtail, you might also look for information on butterflies, moths, insects, ... (BT, NT, RT, definition, note, ...)

“Terminology” (continued)

- Classifications – “buckets” for various statistical and categorization purposes. Example: Classification of Diseases Edition 9 with clinical modifications (ICD-9-CM) – 250.01 “Diabetes mellitus without complication type 1 not stated as uncontrolled”
- Formal Logic Systems – Web Ontology Language (OWL), OBO, Common Logic, others. - classes, individuals, relationships. SNOMED-CT, Gene Ontology, FMA, ... as well as CYC, SUMO, and others

Why Terminology Services?

Start with the country codes:

- Where do you download them?
- What format are they in?
- How are they organized? How do I list just EU countries? African countries?
- Oh – they change???? How do I know when and what?

Why Terminology Services?

Now I've got them loaded...

- I construct some SQL queries to create a dropdown list for a form...
- ... I write some more to create an Ajax App on a web page
- ... and some more to print country names on a report
- ...
- The new accounting package uses three character codes? Ack. I write a conversion
- Oh – they haven't updated their tables? What do we do with "YU"?
- ISO *reuses* codes?????

Why Terminology Services?

- We need to export our data to our new owner – they have completely different tables...
- ... or they've never heard of ISO and they use 01 – 299 for countries...
- ... and they want to know what currencies are (and were) used in a given country ...

Why Terminology Services

Now, take the problems above and figure that a reasonably complex business such as a medical practice has to deal with *hundreds* of tables / classifications / logic systems...

... each with its own formats, labels, rules, ...

... *many* separate application providers that create and consume terminologies..

... and data exchange requirements with competing, complementary businesses

... and an ever increasing load of reporting / analysis / billing requirements..

And you need to stop and ask – isn't there some way we can manage all of this stuff in one place (or at least in one way...)

Sample Terminology Service Applications

- Maintenance of choices for forms and data
- Translation / mapping between values in data
- Indexing – both NLP and manual
- Classification
- Subsumption testing
- Model granularity translation
- Pick list translation
- Definitions / examples / neighborhood (hoverbox type work)

Terminology Services

Goal is to specify a common set of interfaces to:

- Import
- Query
- Update
- Create Updates
- Export
- Reason about

Terminology *and* its relationships to data

CTS₂

Background

Common Terminology Services Edition 2

Derived from:

- **OMG LQS Specification (1999)**
 - OO Model, read only, but laid most of the groundwork
- **HL7 CTS Specification (2004)**
 - ANSI and ISO Standard
 - SOA Model, read only, reduced scope from LQS

CTS₂

Will consist of:

- 1) A “Service Functional Model” – a CIM and a collection of requirements
- 2) An OMG RFP – done through the Ontology PSIG
- 3) A submission with a PIM and at least one PSM
- 4) An implementation (!)

CTS₂

Additional Drivers and Requirements

- NCI/Mayo LexEVS compatibility
- Semantic Web / Ontology community buy-in
- BioPortal compatibility
 - RESTful compatible architecture
- Alignment w/ I4SM model
 - Reasoning
 - Z representation
- OMV alignment
- API4KB Alignment
- Addl: Phin VADS, HL7 MIF

CTS₂

Mayo/II4SM submission (Apelon, Sandpiper, Visumpoint as supporters) is targeting both SOA and ROA

ROA leads to some really interesting (and useful) modeling decisions...

ROA

That's the Resource-Oriented Architecture. It's just four concepts:

- Resources
- Their names (URIs)
- Their representations
- The links between them

and four properties:

- Addressability
- Statelessness
- Connectedness
- A uniform interface

CTS₂ Resource “Profiles”

Abstract Resource

- Code System
- Map
- Value Set
- Concept Domain

Resource Version

- Code System Version
- Map Version
- Value Set Definition
- Concept Domain Binding

Changeable

Entity

Association

Map Entry

Statement

CTS₂ Function “Profiles”

- Read
- Query/Search (w/ iterators)
- Import / Export (external formats)
- Incremental Update
- Resource History Query
- Update Creation
- Temporal Query
- Resource specific (reasoning, value set comparison, etc.)

Modeling Approach

- UML Structure
- Z Semantics (invariants, preconditions, postconditions)
- Text in the middle

Experience, Issues, Questions

- What, exactly *is* a PIM?
 - Not obvious
 - Z helps (“you need a precise way to describe business processes”)
 - What of URIs (IRI, interestingly is probably not PIM?)
- SOA, ROA, Pojo requirements
 - Pre- vs. post-orchestration
 - Choreography – in scope?
 - Error handling

Experience, Issues, Questions

- Z issues
 - Precise vs. Detailed (Kilov)
 - Precision has a cost (and benefit?)
 - Allergies, LaTeX and machinability...
- REST issues
 - Identity for triples (arm part of body)
- RDF/OWL vs. traditional model
- Agility – this is (sort of) waterfall writ large...

class DataTypes

«dataType»
String

«dataType»
LocalIdentifier

«dataType»
DateAndTime

«dataType»
NamespaceIdentifier

«dataType»
Enumeration

«dataType»
MatchStrength

«dataType»
URI

«dataType»
NaturalNumber

«dataType»
IRI

«dataType»
AmountOfTime

«dataType»
LRI

CTS₂ and RDF

- (i)RDF – a “canonical” map from CTS₂ to RDF tags.
- Statement Model

class CodeSystem

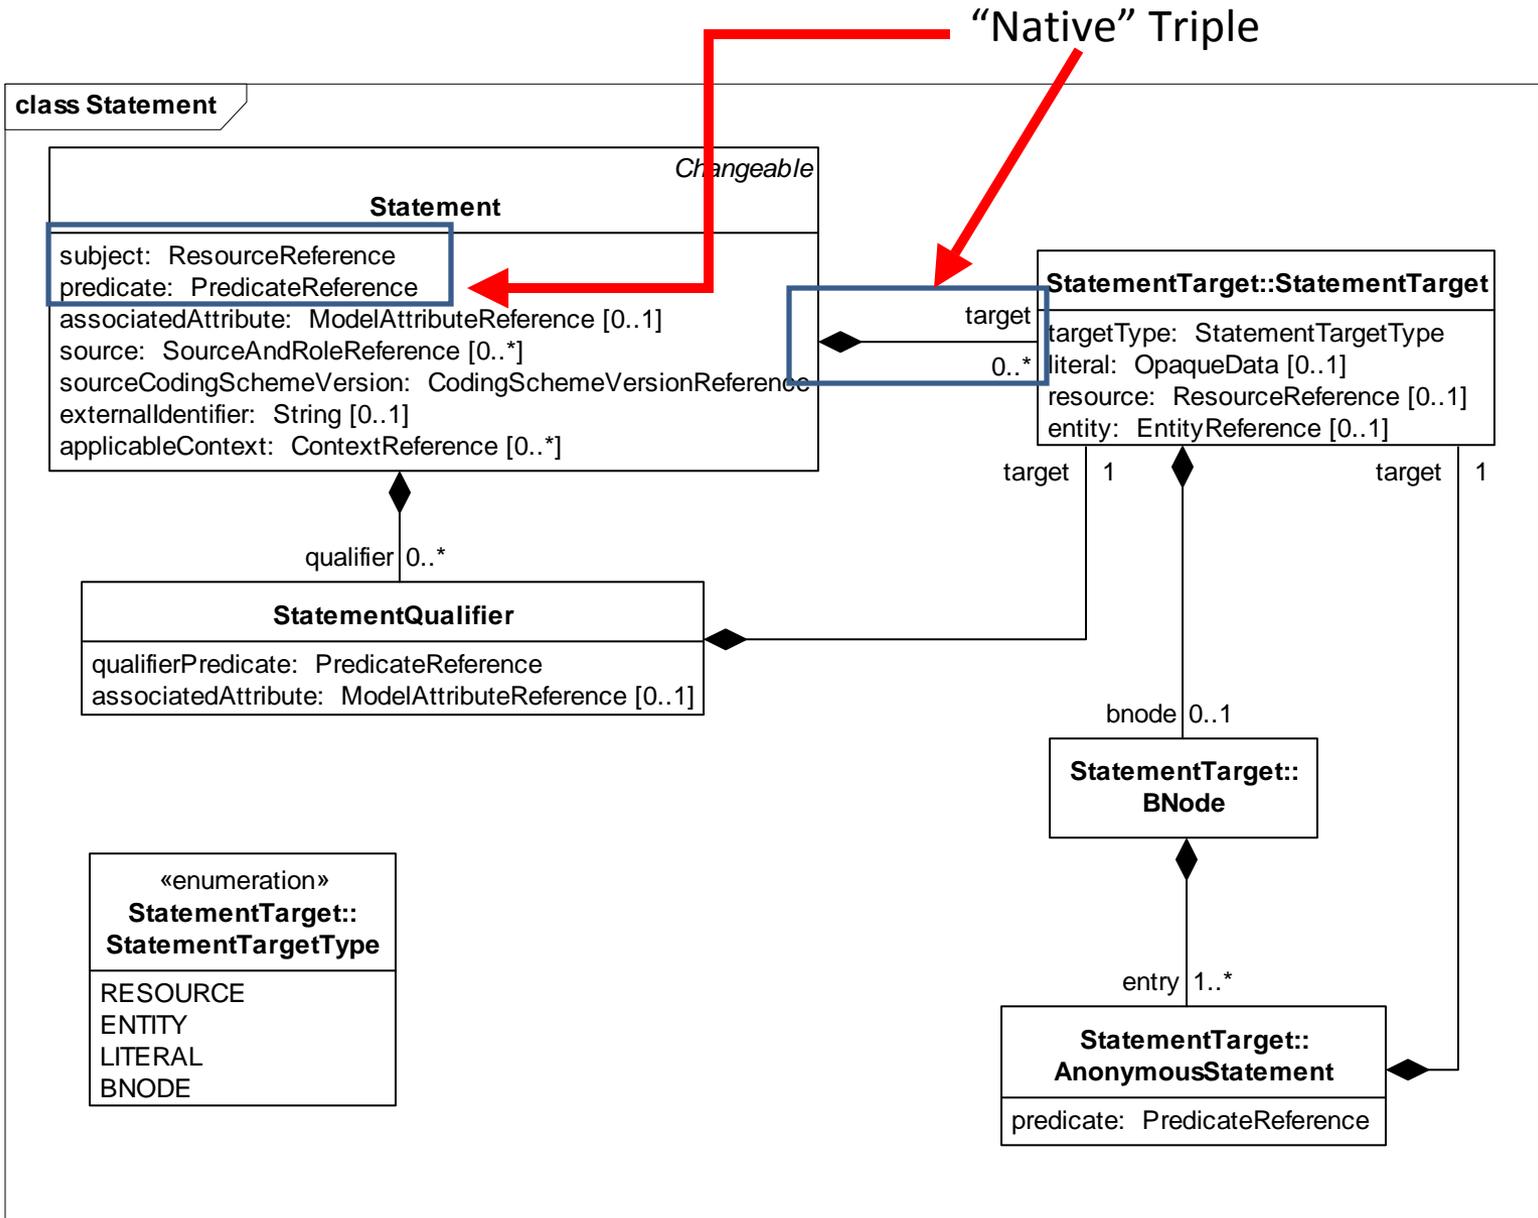

AbstractResourceDescription

CodeSystem

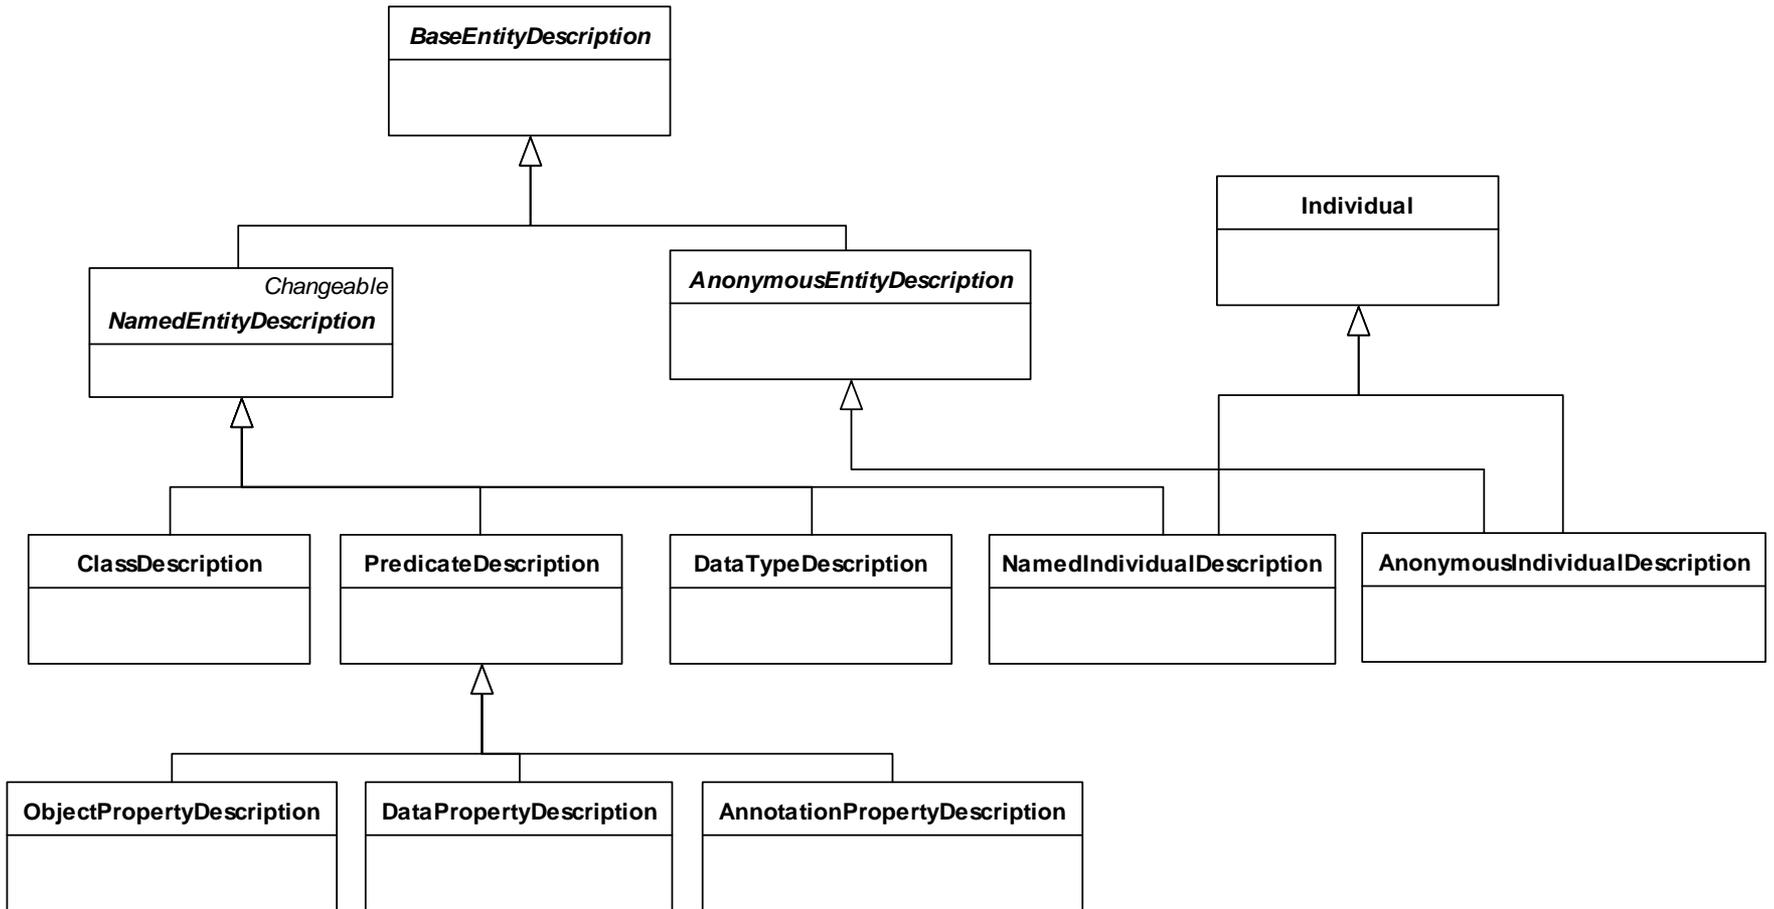

codeSystemName: CodeSystemName
codeSystemType: CodeSystemType [0..1]

::Changeable
entryID: URI
entryState: EntryState
status: StatusReference [0..1]
owner: SourceReference [0..1]

None of the above

Derivation

class EntityDescriptionTypes

One more note

Terminology forms a component of both the information and behavioral semantics of a model. Even if you don't use terminology services, or anything more than enumerated dropdown lists, you need to agree on the meaning and behavior of the terminology

CTS₂ provides a meta-model of static and dynamic terminology behavior that allows reasonable terminology model analysis (!)
