

Basic Web Services Technologies Review

➤ XML Technologies

- “Extensible Markup Language”
- Base XML for documents
- XML Schema for describing XML documents

➤ SOAP

- A simple way to send documents (some people have called it “email for documents”)
- How to format XML documents for transmission

➤ WSDL - Web Services Description Language

- Defines implementation details about a service

➤ UDDI - Universal Description, Discovery and Integration

- Store, advertise and discover services

Basic Web Services Architecture

Advanced Web Services Topics

- › Enterprise Web Services
- › Industry trends and organizations
- › Security and Reliability
- › Transactions
- › Metadata and Policy
- › Choreography and Orchestration
 - Composite web services
- › Interoperability Requirements
 - Encoding discussion
- › Futures

Enterprise Web Services

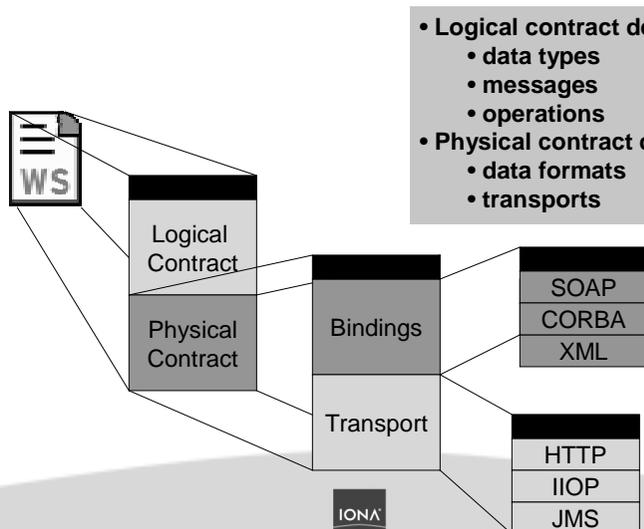

- › Extending WS throughout the enterprise and among enterprises ⇒ greater emphasis on Qualities Of Service (QoS)
 - › Security, Reliability, Transactions, Scalability
 - › Systems Management, Policy, Metadata Management/Governance
 - › Interoperability
- › It's also important to support multiple transports and data formats (other than SOAP over HTTP):
 - › IIOP & RMI
 - › WebSphereMQ
 - › TIBCO Rendezvous
 - › Tuxedo
 - › FTP
 - › JMS

Making Software Work Together™

5

Extending WSDL Contracts

- Logical contract defines
 - data types
 - messages
 - operations
- Physical contract defines:
 - data formats
 - transports

Making Software Work Together™

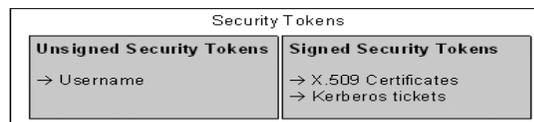

6

Security

- › Confidentiality – no one can see my data
- › Integrity – my data gets there in one piece
- › Authentication – a user or program is confirmed to be who they say they are
- › Authorization – ensuring access to services and data only by those who are supposed to access them
- › No overall architecture yet defined
 - May include firewalls, proxies, security servers, and identity management
- › WS-Security is a well-agreed framework (OASIS)

SOAP Header example (WS-Security)

```
<S11:Envelope xmlns:S11="..." xmlns:wsse="..." xmlns:wsu="..." xmlns:ds="...">
  <S11:Header>
    <wsse:Security xmlns:wsse="...">
      <fabtok:CustomToken wsu:Id="MyID" xmlns:fabtok="http://fabr123/token" />

      <ds:Signature> . . . </ds:Signature>
      <ds:SignedInfo> . . . </ds:SignedInfo>
    </wsse:Security>
  </S11:Header>
  ...
</S11:Envelope>
```

Reliability requirements

- Reliability of message delivery is critical to many applications
 - Guarantee of message delivery (both request and response)
 - At least once (duplicates are allowed)
 - At most once ("best effort", ok to drop some messages)
 - Once and only once – the toughest to guarantee!
 - Eliminate duplicates (if any)
 - Preserve message ordering (when important)

- Some of these features are provided as standard when WS are carried on a connection-oriented protocol
 - The "sessions" and correlation IDs of the connection-oriented protocol ensures features such as ordering
 - But some QoS must still be added (e.g., store-and-forward to allow clients to send messages even if a server isn't running)

Example message flow: WS-ReliableMessaging

Web Services: Implications for TP

- **Persistent sessions are missing from HTTP**
 - Need to define a common context sharing mechanism
 - Transport “agnostic” means LCD
 - It’s difficult to write a new WS spec that assumes a more sophisticated protocol than HTTP
- **Need a solution that is also suited for document-oriented transactions**
 - Compensation, transactional “queues” needed
 - Reliable messaging needed
- **Business process orchestration**
 - Cancel/adjust transactions in long-running flight
 - Mixture of existing and new technologies

Current status of standardization

- **OASIS WS-Composite Application Framework (WS-CAF)**
 - Factors out context into WS-Context specification
 - Coordinates across different types of systems
 - Resolves the differences in the co-ordinator, not in the end-points
- **OASIS WS-TX:**
 - WS-Coordination
 - WS-Atomic Transactions
 - WS-Business Activity

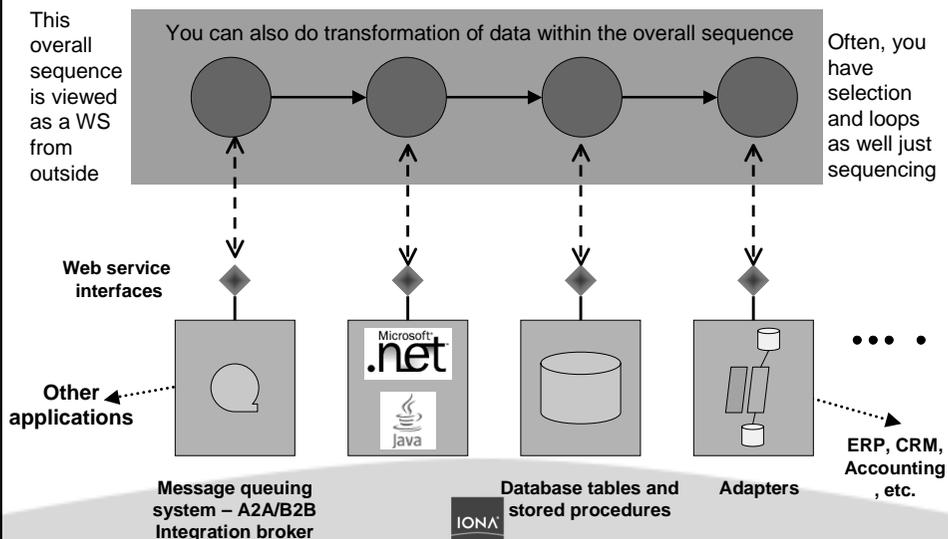

Web Services Composition

- Once you have a “critical mass” of Web services, you may want to:
 - link them together to create (composite) complex Web services
 - implement whole business processes based on those services
- Of course you can “hard-code” this, but the result is
 - inflexible (hard to maintain)
 - proprietary, not explicit (business logic will be buried in code)
- Better: Standardized high-level mechanisms
 - Standardized declarative, non-programmatic way to compose sequences of web service calls to accomplish a business function
- Efforts ongoing to provide
 - WS-BPEL (seems to be winning at present) for run-time
 - WS-Choreography (more B2B oriented) between partners

Orchestration Architecture

Metadata and policy requirements

➤ Need to add information to WSDL to specify:

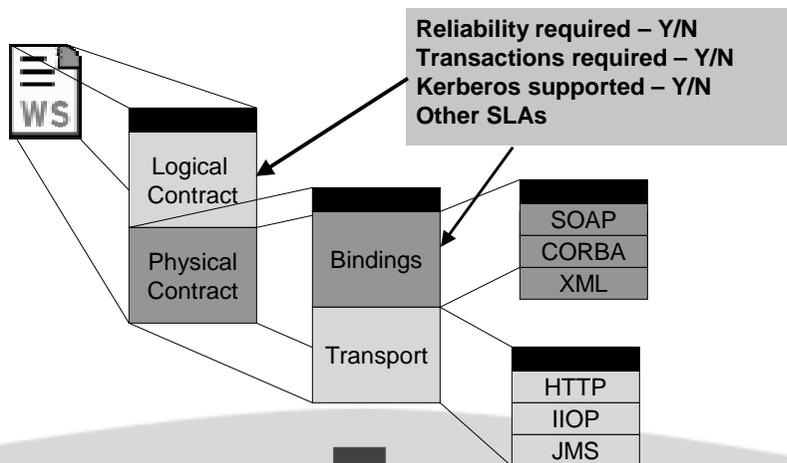

- Reliability
- Security
- Transactions
- High Availability, Service Level Agreements, etc.

➤ WSDLs define only part of the SOA contract

- Need to attach policy assertions to define quality of service and service level agreement requirements
- Can use WS-MetadataExchange to retrieve
- Store and manage in UDDI

Extending WSDL Contracts - Policy

Interoperability Requirements

- Within the enterprise and among enterprises
 - Across hardware platforms, operating systems, programming languages, middleware and component technologies
- SoapBuilders and WS-I have been working to correlate the many WS standards into more interoperable configurations. E.g.,
 - Defining a consistent selection of standards
 - Subsetting (“profiling”) a standard
- Ensuring compatible message *encoding* is another key part of interoperability
 - As discussed in the new few slides

You have a choice of the encoding for complex data in msgs

- The WS-I recommendation is *literal*
 - This uses XMLSchema in the normal way
 - The message references a schema that defines the elements and types for formatting arrays, sequences, records/structures, and other complex types
 - The message uses these elements and types
- The alternative is SOAP *encoded*
 - This defines a set of elements that can be used for complex data
 - Mostly, these elements were good at formatting data that typically arises in RPC calls
 - It was first introduced before XMLSchema was available
 - Harder to achieve broad interoperability
 - Especially when using more complex data types

You also have a choice between two message styles

- The choice is *rpc* or *document*
document style is recommended by WS-I
many existing Web services use *rpc* style)
- Operation have input and (optional) output messages

In *rpc* style, each message can have zero or more parts

```
<message name="getQuoteRequest">  
  <part name="symbol" type="s:string">  
  <part name="date" type="s:string">  
</message>
```

In *document* style, each message have one part

An XML element, not a type

Making Software Work Together WS-I has yet to profile SOAP 1.2

Industry organizations

- Developing Web services standards

W3C

- XML, SOAP (XMLP working group), WSDL, WS-Addressing, WS-Choreography, Semantic Web Services

OASIS

- UDDI, WS-Security, WS-Reliable Exchange, WS-Transactions, WS-CAF, WS-Notification, WS-Secure Exchange, etc.

JCP (Java Community Process)

- JAX-RPC, JWSDL, JAXM, JAXR, ...

WS-I

- Basic profile, security profile, etc.

OMG

- IDL to WSDL, WSDL to IDL (WSDL 1.1), WSDL to C++

Making Software Work Together™

Futures -

➤ Advances in Standards

Ratification of newer versions of standards (SOAP, WSDL, etc.)

Emergence of newer standards to support the evolution of WS into enterprise environments

Service Component Architecture (SCA)

SOA Tools (Eclipse)

➤ Advances in deployment support

Additional availability of transports/protocols in distributed infrastructures

➤ Interoperability advances

More shake-out of interoperability issues
