Business Process Model and Notation (BPMN)

Version 2.0

OMG Document Number: dtc/2010-06-05
Standard document URL: http://www.omg.org/spec/BPMN/2.0

This OMG document replaces the submission document (bmi/2009-05-03, Alpha). It is an OMG Adopted Beta Specification and is currently in the finalization phase. Comments on the content of this document are welcome, and should be directed to issues@omg.org by March 1, 2010.

You may view the pending issues for this specification from the OMG revision issues web page http://www.omg.org/issues/.

The FTF Recommendation and Report for this specification will be published on June 21, 2010. If you are reading this after that date, please download the available specification from the OMG Specifications Catalog.
USE OF SPECIFICATION - TERMS, CONDITIONS & NOTICES

The material in this document details an Object Management Group specification in accordance with the terms, conditions and notices set forth below. This document does not represent a commitment to implement any portion of this specification in any company's products. The information contained in this document is subject to change without notice.

LICENSES

The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

Subject to all of the terms and conditions below, the owners of the copyright in this specification hereby grant you a fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use this specification to create and distribute software and special purpose specifications that are based upon this specification, and to use, copy, and distribute this specification as provided under the Copyright Act; provided that: (1) both the copyright notice identified above and this permission notice appear on any copies of this specification; (2) the use of the specifications is for informational purposes and will not be copied or posted on any network computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3) no modifications are made to this specification. This limited permission automatically terminates without notice if you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the specifications in your possession or control.

PATENTS

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.
GENERAL USE RESTRICTIONS

Any unauthorized use of this specification may violate copyright laws, trademark laws, and communications regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved. No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic, electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems--without permission of the copyright owner.

DISCLAIMER OF WARRANTY

WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE OR USE. IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The entire risk as to the quality and performance of software developed using this specification is borne by you. This disclaimer of warranty constitutes an essential part of the license granted to you to use this specification.

RESTRICTED RIGHTS LEGEND

Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1) (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)(1) and (2) of the Commercial Computer Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as indicated above and may be contacted through the Object Management Group, 140 Kendrick Street, Needham, MA 02494, U.S.A.

TRADEMARKS

MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are registered trademarks of the Object Management Group, Inc., and Object Management Group™, OMG™, Unified Modeling Language™, Model Driven Architecture Logo™, Model Driven Architecture Diagram™, CORBA logos™, XMI Logo™, CWM™, CWM Logo™, IIOP™, IMM™, MOF™, OMG Interface Definition Language (IDL)™, and OMG Systems Modeling Language (OMG SysML)™ are trademarks of the Object Management Group. All other products or company names mentioned are used for identification purposes only, and may be trademarks of their respective owners.

COMPLIANCE

The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer
software to use certification marks, trademarks or other special designations to indicate compliance with these materials.

Software developed under the terms of this license may claim compliance or conformance with this specification if and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this specification, but may not claim compliance or conformance with this specification. In the event that testing suites are implemented or approved by Object Management Group, Inc., software developed using this specification may claim compliance or conformance with the specification only if the software satisfactorily completes the testing suites.
OMG’s Issue Reporting Procedure

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page http://www.omg.org, under Documents, Report a Bug/Issue (http://www.omg.org/technology/agreement.htm).
## Table of Contents

Preface xxiii

1 Scope ................................................................................................................................. 1

2 Conformance ...................................................................................................................... 1

2.1 Process Modeling Conformance ..................................................................................... 2

2.1.1 BPMN Process Types ............................................................................................... 2

2.1.2 BPMN Process Elements ......................................................................................... 2

2.1.3 Visual Appearance ....................................................................................................... 8

2.1.4 Structural Conformance ............................................................................................ 8

2.1.5 Process Semantics ...................................................................................................... 8

2.1.6 Attributes and Model Associations .......................................................................... 9

2.1.7 Extended and Optional Elements ............................................................................. 9

2.1.8 Visual Interchange ..................................................................................................... 9

2.2 Process Execution Conformance .................................................................................... 9

2.2.1 Execution Semantics .................................................................................................. 10

2.2.2 Import of Process Diagrams .................................................................................... 10

2.3 BPEL Process Execution Conformance ........................................................................ 10

2.4 Choreography Modeling Conformance .......................................................................... 10

2.4.1 BPMN Choreography Types .................................................................................... 10

2.4.2 BPMN Choreography elements ............................................................................... 10

2.4.3 Visual Appearance ..................................................................................................... 11

2.4.4 Choreography Semantics ......................................................................................... 11

2.4.5 Visual Interchange ..................................................................................................... 11

2.5 Summary of BPMN Conformance Types ..................................................................... 12

3 Normative References ..................................................................................................... 12

3.1 Normative .................................................................................................................... 12

3.2 Non-Normative ............................................................................................................. 13

4 Terms and Definitions ...................................................................................................... 16

5 Symbols ............................................................................................................................. 16

6 Additional Information ..................................................................................................... 16

6.1 Conventions .................................................................................................................... 16

6.1.1 Typographical and Linguistic Conventions and Style ...................................... 16

6.1.2 Abbreviations ........................................................................................................... 17

6.2 Structure of this Document ......................................................................................... 17

6.3 Acknowledgements ....................................................................................................... 17

7 Overview ........................................................................................................................... 21

7.1 BPMN Scope ............................................................................................................... 22

7.1.1 Uses of BPMN ........................................................................................................... 23

7.2 BPMN Elements .......................................................................................................... 27

7.2.1 Basic BPMN Modeling Elements ....................................................................... 28
12.2.2 Abstract Syntax............................................................................................378
12.2.3 Classifier Descriptions................................................................................381
12.2.4 Complete BPMN DI XML Schema ...............................................................389
12.3 Notational Depiction Library and Abstract Element Resolutions ................391
   12.3.1 Labels ..........................................................................................................391
   12.3.2 BPMNShape ................................................................................................392
   12.3.3 BPMNEdge ..................................................................................................423
12.4 Example(s) .................................................................................................424
   12.4.1 Depicting Content in a Sub-Process ............................................................425
   12.4.2 Multiple Lanes and Nested Lanes.................................................................430
   12.4.3 Vertical Collaboration ................................................................................432
   12.4.4 Conversation ...............................................................................................434
   12.4.5 Choreography .............................................................................................436
13 BPMN Execution Semantics.............................................................................439
   13.1 Process Instantiation and Termination .........................................................440
   13.2 Activities .........................................................................................................440
      13.2.1 Sequence Flow Considerations .................................................................441
      13.2.2 Activity ......................................................................................................442
      13.2.3 Task ............................................................................................................444
      13.2.4 Sub-Process/Call Activity ...........................................................................444
      13.2.5 Ad-Hoc Sub-Process ..................................................................................445
      13.2.6 Loop Activity .............................................................................................446
      13.2.7 Multiple Instances Activity .......................................................................446
   13.3 Gateways .........................................................................................................448
      13.3.1 Parallel Gateway (Fork and Join).................................................................448
      13.3.2 Exclusive Gateway (Exclusive Decision (data-based) and Exclusive Merge)449
      13.3.3 Inclusive Gateway (Inclusive Decision and Inclusive Merge) .....................450
      13.3.4 Event-based Gateway (Exclusive Decision (event-based)) .........................452
      13.3.5 Complex Gateway (related to Complex Condition and Complex Merge) ....452
   13.4 Events .............................................................................................................455
      13.4.1 Start Events ...............................................................................................455
      13.4.2 Intermediate Events ................................................................................455
      13.4.3 Intermediate Boundary Events ................................................................455
      13.4.4 Event Sub-Processes ...............................................................................456
      13.4.5 Compensation ..........................................................................................456
      13.4.6 End Events ...............................................................................................458
14 Mapping BPMN Models to WS-BPEL.................................................................461
   14.1 Basic BPMN-BPEL Mapping ...........................................................................462
      14.1.1 Process .......................................................................................................463
      14.1.2 Activities ..................................................................................................464
      14.1.3 Events ......................................................................................................471
      14.1.4 Gateways and Sequence Flows ................................................................477
      14.1.5 Handling Data ..........................................................................................481
   14.2 Extended BPMN-BPEL Mapping .................................................................485
      14.2.1 End Events ...............................................................................................485
      14.2.2 Loop/Switch Combinations From a Gateway ............................................486
      14.2.3 Interleaved Loops ....................................................................................486
      14.2.4 Infinite Loops ..........................................................................................489

Preface

About the Object Management Group

OMG

Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer industry standards consortium that produces and maintains computer industry specifications for interoperable, portable and reusable enterprise applications in distributed, heterogeneous environments. Membership includes Information Technology vendors, end users, government agencies and academia.

OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle approach to enterprise integration that covers multiple operating systems, programming languages, middleware and networking infrastructures, and software development environments. OMG's specifications include: UML® (Unified Modeling Language™); CORBA® (Common Object Request Broker Architecture); CWM™ (Common Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

More information on the OMG is available at http://www.omg.org/.

OMG Specifications

As noted, OMG specifications address middleware, modeling and vertical domain frameworks. A catalog of all OMG Specifications is available from the OMG website at:

Specifications within the Catalog are organized by the following categories:

OMG Modeling Specifications
- UML
- MOF
- XMI
- CWM
- Profile specifications.

OMG Middleware Specifications
- CORBA/IIOP
- IDL/Language Mappings
- Specialized CORBA specifications
- CORBA Component Model (CCM)

Platform Specific Model and Interface Specifications
- CORBAservices
• CORBA facilities
• OMG Domain specifications
• OMG Embedded Intelligence specifications
• OMG Security specifications.

All of OMG’s formal specifications may be downloaded without charge from our website. (Products implementing OMG specifications are available from individual suppliers.) Copies of specifications, available in PostScript and PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management Group, Inc. at:

OMG Headquarters
140 Kendrick Street
Building A, Suite 300
Needham, MA 02494
USA
Tel: +1-781-444-0404
Fax: +1-781-444-0320
Email: pubs@omg.org

Certain OMG specifications are also available as ISO standards. Please consult http://www.iso.org

**Typographical Conventions**

The type styles shown below are used in this document to distinguish programming statements from ordinary English. However, these conventions are not used in tables or section headings where no distinction is necessary.

Times/Times New Roman - 10 pt.: Standard body text

Helvetica/Arial - 10 pt. Bold: OMG Interface Definition Language (OMG IDL) and syntax elements.

**Courier - 10 pt. Bold:** Programming language elements.

Helvetica/Arial - 10 pt: Exceptions

**Note** – Terms that appear in *italics* are defined in the glossary. Italic text also represents the name of a document, specification, or other publication.

**Issues**

The reader is encouraged to report any technical or editing issues/problems with this specification to http://www.omg.org/technology/agreement.htm.
1 Scope

The Object Management Group (OMG) has developed a standard Business Process Model and Notation (BPMN). The primary goal of BPMN is to provide a notation that is readily understandable by all business users, from the business analysts that create the initial drafts of the processes, to the technical developers responsible for implementing the technology that will perform those processes, and finally, to the business people who will manage and monitor those processes. Thus, BPMN creates a standardized bridge for the gap between the business process design and process implementation.

Another goal, but no less important, is to ensure that XML languages designed for the execution of business processes, such as WSBPEL (Web Services Business Process Execution Language), can be visualized with a business-oriented notation.

This specification represents the amalgamation of best practices within the business modeling community to define the notation and semantics of Collaboration diagrams, Process diagrams, and Choreography diagrams. The intent of BPMN is to standardize a business process model and notation in the face of many different modeling notations and viewpoints. In doing so, BPMN will provide a simple means of communicating process information to other business users, process implementers, customers, and suppliers.

The membership of the OMG has brought forth expertise and experience with many existing notations and has sought to consolidate the best ideas from these divergent notations into a single standard notation. Examples of other notations or methodologies that were reviewed are UML Activity Diagram, UML EDOC Business Processes, IDEF, ebXML BPSS, Activity-Decision Flow (ADF) Diagram, RosettaNet, LOVeM, and Event-Process Chains (EPCs).

2 Conformance

Software can claim compliance or conformance with BPMN 2.0 if and only if the software fully matches the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points can claim only that the software was based on this specification, but cannot claim compliance or conformance with this specification. The specification defines four types of conformance namely Process Modeling Conformance, Process Execution Conformance, BPEL Process Execution Conformance and Choreography Modeling Conformance.

The implementation claiming conformance to Process Modeling Conformance type is NOT REQUIRED to support Choreography Modeling Conformance type and vice-versa. Similarly, the implementation claiming Process Execution Conformance type is NOT REQUIRED to be conformant to the Process Modeling and Choreography Conformance types.

The implementation claiming conformance to the Process Modeling Conformance type SHALL comply with all of the requirements set forth in Section 2.1. The implementation claiming conformance to the Process Execution Conformance type SHALL comply with all of the requirements set forth in Section 2.2. The implementation claiming conformance to the BPEL Process Execution Semantics Conformance type SHALL comply with all of the requirements set forth in Section 2.3. The implementation claiming conformance to the Choreography Conformance type SHALL comply with all of the requirements set forth in Section 2.4. The implementation is said to have BPMN Complete Conformance if it complies with all of the requirements stated in Sections 2.1, 2.2, 2.3, and 2.4.
2.1 Process Modeling Conformance

The next eight (8) sections describe **Process Modeling Conformance**.

2.1.1 BPMN Process Types

The implementations claiming **Process Modeling Conformance** MUST support the following **BPMN** packages:

- The **BPMN** core elements, which include those defined in the *Infrastructure, Foundation, Common, and Service* packages (see Chapter 8).
- **Process** diagrams, which include the elements defined in the *Process, Activities, Data, and Human Interaction* packages (see Chapter 10).
- **Collaboration** diagrams, which include *Pools* and *Message Flow* (see Chapter 9).
- **Conversation** diagrams, which include *Pools, Conversations*, and *Conversation Links* (see Chapter 9).

As an alternative to full **Process Modeling Conformance**, there are three (3) conformance sub-classes defined:

- **Descriptive**
- **Analytic**
- **Common Executable**

**Descriptive** is concerned with visible elements and attributes used in high-level modeling. It should be comfortable for analysts who have used BPA flowcharting tools.

**Analytic** contains all of **Descriptive** and in total about half of the constructs in the full **Process Modeling Conformance** Class. It is based on experience gathered in BPMN training and an analysis of user-patterns in the Department of Defense Architecture Framework and planned standardization for that framework.

Both **Descriptive** and **Analytic** focus on visible elements and a minimal subset of supporting attributes/elements.

**Common Executable** focuses on what is needed for executable process models.

Elements and attributes not in these sub-classes are contained in the full **Process Modeling Conformance** class.

The elements for each sub-class are defined in the next section.

2.1.2 BPMN Process Elements

The **Process Modeling Conformance** type set consists of **Collaboration** and **Process** diagram elements, including all **Task** types, **embedded Sub-Processes, CallActivity**, all **Gateway** types, all **Event** types (**Start, Intermediate, and End**), **Lane, Participants, Data Object** (including **DataInput** and **DataOutput**), **Message, Group, Text Annotation, Sequence Flow** (including **conditional** and **default** flows), **Message Flow, Conversations** (limited to grouping **Message Flow**, and associating **correlations**), **Correlation**, and **Association** (including **Compensation Association**). The set also includes markers (**Loop, Multi-Instance, Transaction, Compensation**) for **Tasks** and **embedded Sub-Processes**.

**Note**: Implementations are not expected to support **Choreography** modeling elements such as **Choreography Task** and **Sub-Choreography**.

For a tool to claim support for a sub-class the following criteria MUST be satisfied:

- All the elements in the sub-class MUST be supported.

Business Process Model and Notation, v2.0
◆ For each element, all the listed attributes MUST be supported.
◆ In general, if the sub-class doesn't mention an attribute and it is NOT REQUIRED by the schema then it is not in the subclass. Exceptions to this rule are noted.

### Descriptive Conformance Sub-Class

The **Descriptive** conformance sub-class elements shown in Table 2.1:

#### Table 2.1 – Descriptive Conformance Sub-Class Elements and Attributes

</tr>
</tbody>
</table>

\(^a\)\text{Data Association} is ABSTRACT: \text{Data Input Association} and \text{Data Output Association} will appear in the XML serialization. These both have REQUIRED attributes\([\text{sourceRef} \text{ and } \text{targetRef}]\) which refer to \text{itemAwareElements}. To be consistent with the metamodel, this will require the following additional elements: \text{ioSpecification}, \text{inputSet}, \text{outputSet}, \text{Data Input}, \text{Data Output}. When a BPMN editor draws a \text{Data Association} to an \text{Activity} or \text{Event} it should generate this supporting invisible substructure. Otherwise, the metamodel would have to be changed to make \text{sourceRef} and \text{targetRef} optional or allow reference to non-\text{itemAwareElements}, e.g. \text{Activity} and \text{Event}.

\(^b\)\text{associationDirection} not specified for \text{Data Association}

\(^c\)\text{Documentation} is not a visible element. It is an attribute of most elements.

</table>

---

\(^a\)ConditionExpression, allowed only for **Sequence Flow** out of **Gateways**, MAY be null.

\(^b\)Default is an attribute of a sourceRef (exclusive or inclusive) **Gateway**.

\(^c\)Note that **messageRef**, an attribute of various message **Events**, is optional and not in the sub-class.

**Common Executable Conformance Sub-Class**

This conformance sub-class is intended for modeling tools that can emit executable models.
Data type definition language MUST be XML Schema.
Service Interface definition language MUST be WSDL.
Data access language MUST be XPath.

The **Common Executable** conformance sub-class elements are shown in Table 2.3 and and its supporting classes in Table 2.4:

Table 2.3. – Common Executable Conformance Sub-Class Elements and Attributes

<sup>a</sup> Structure MUST be defined by an XSD Complex Type
<sup>b</sup>
2.1.3 Visual Appearance

A key element of BPMN is the choice of shapes and icons used for the graphical elements identified in this specification. The intent is to create a standard visual language that all process modelers will recognize and understand. An implementation that creates and displays BPMN Process Diagrams SHALL use the graphical elements, shapes, and markers illustrated in this specification.

Note – There is flexibility in the size, color, line style, and text positions of the defined graphical elements, except where otherwise specified (see page 41).

The following extensions to a BPMN Diagram are permitted:

- New markers or indicators MAY be added to the specified graphical elements. These markers or indicators could be used to highlight a specific attribute of a BPMN element or to represent a new subtype of the corresponding concept.
- A new shape representing a kind of Artifact MAY be added to a Diagram, but the new Artifact shape SHALL NOT conflict with the shape specified for any other BPMN element or marker.
- Graphical elements MAY be colored, and the coloring MAY have specified semantics that extend the information conveyed by the element as specified in this standard.
- The line style of a graphical element MAY be changed, but that change SHALL NOT conflict with any other line style REQUIRED by this specification.
- An extension SHALL NOT change the specified shape of a defined graphical element or marker. (e.g., changing a square into a triangle, or changing rounded corners into squared corners, etc.).

2.1.4 Structural Conformance

An implementation that creates and displays BPMN diagrams SHALL conform to the specifications and restrictions with respect to the connections and other diagrammatic relationships between graphical elements. Where permitted or requested connections are specified as conditional and based on attributes of the corresponding concepts, the implementation SHALL ensure the correspondence between the connections and the values of those attributes.

Note – In general, these connections and relationships have specified semantic interpretations, which specify interactions among the process concepts represented by the graphical elements. Conditional relationships based on attributes represent specific variations in behavior. Structural conformance therefore guarantees the correct interpretation of the diagram as a specification of process, in terms of flows of control and information. Throughout the document, structural specifications will appear in paragraphs using a special shaped bullet: Example: ♦ A TASK MAY be a target for Sequence Flow; it can have multiple incoming Flows. An incoming Flow MAY be from an alternative path and/or parallel paths.

2.1.5 Process Semantics

This specification defines many semantic concepts used in defining Processes, and associates them with graphical elements, markers, and connections. To the extent that an implementation provides an interpretation of the BPMN diagram as a semantic specification of Process, the interpretation SHALL be consistent with the semantic interpretation herein specified. In other words, the implementation claiming BPMN Process Modeling Conformance has to support the semantics surrounding the diagram elements expressed in Chapter 10.
Note – The implementations claiming Process Modeling Conformance are not expected to support the BPMN execution semantics described in Chapter 13.

2.1.6 Attributes and Model Associations

This specification defines a number of attributes and properties of the semantic elements represented by the graphical elements, markers, and connections. Some of these attributes are purely representational and are so marked, and some have mandated representations. Some attributes are specified as mandatory, but have no representation or only optional representation. And some attributes are specified as optional. For every attribute or property that is specified as mandatory, a conforming implementation SHALL provide some mechanism by which values of that attribute or property can be created and displayed. This mechanism SHALL permit the user to create or view these values for each BPMN element specified to have that attribute or property. Where a graphical representation for that attribute or property is specified as REQUIRED, that graphical representation SHALL be used. Where a graphical representation for that attribute or property is specified as optional, the implementation MAY use either a graphical representation or some other mechanism. If a graphical representation is used, it SHALL be the representation specified. Where no graphical representation for that attribute or property is specified, the implementation MAY use either a graphical representation or some other mechanism. If a graphical representation is used, it SHALL NOT conflict with the specified graphical representation of any other BPMN element.

2.1.7 Extended and Optional Elements

A conforming implementation is NOT REQUIRED to support any element or attribute that is specified herein to be non-normative or informative. In each instance in which this specification defines a feature to be “optional,” it specifies whether the option is in:

- how the feature will be displayed
- whether the feature will be displayed
- whether the feature will be supported

A conforming implementation is NOT REQUIRED to support any feature whose support is specified to be optional. If an implementation supports an optional feature, it SHALL support it as specified. A conforming implementation SHALL support any “optional” feature for which the option is only in whether or how it SHALL be displayed.

2.1.8 Visual Interchange

One of the main goals of this specification is to provide an interchange format that can be used to exchange BPMN definitions (both domain model and diagram layout) between different tools. The implementation should support the metamodel for PROCESS types specified in Section 13.1 to enable portability of process diagrams so that users can take business process definitions created in one vendor’s environment and use them in another vendor’s environment.

2.2 Process Execution Conformance

The next two (2) sections describe Process Execution Conformance.
2.2.1 Execution Semantics

The BPMN execution semantics have been fully formalized in this version of the specification. The tool claiming BPMN Execution Conformance type MUST fully support and interpret the operational semantics and Activity life-cycle specified in Section 14.2.2. Non-operational elements listed in Section 14 MAY be ignored by implementations claiming BPMN Execution Conformance type. Conformant implementations MUST fully support and interpret the underlying metamodel.

**Note** – The tool claiming Process Execution Conformance type is not expected to support and interpret Choreography models. The tool claiming Process Execution Conformance type is not expected to support Process Modeling Conformance. More precisely, the tool is not required to support graphical syntax and semantics defined in this specification. It MAY use different graphical elements, shapes and markers, then those defined in this specification.

2.2.2 Import of Process Diagrams

The tool claiming Process Execution Conformance type MUST support import of BPMN Process diagram types including its definitional Collaboration (see Table 10.1).

2.3 BPEL Process Execution Conformance

Special type of Process Execution Conformance that supports the BPMN mapping to WS-BPEL as specified in Section 15.1 can claim BPEL Process Execution Conformance.

**Note** – The tool claiming BPEL Process Execution Conformance MUST fully support Process Execution Conformance. The tool claiming BPEL Process Execution Conformance is not expected to support and interpret Choreography models. The tool claiming BPEL Process Execution Conformance is not expected to support Process Modeling Conformance.

2.4 Choreography Modeling Conformance

The next five (5) sections describe Choreography Conformance.

2.4.1 BPMN Choreography Types

The implementations claiming Choreography Conformance type MUST support the following BPMN packages:

- The BPMN core elements, which include those defined in the Infrastructure, Foundation, Common, and Service packages (see Chapter 8).
- Choreography diagrams, which includes the elements defined in the Choreography, and Choreography packages (see Chapter 11).
- Collaboration diagrams, which include Pools and Message Flow (see Chapter 9).

2.4.2 BPMN Choreography elements

The Choreography Conformance set includes Message, Choreography Task, Global Choreography Task, Sub-Choreography (expanded and collapsed), certain types of Start Events (e.g., None, Timer, Conditional, Signal, and Multiple), certain types of Intermediate Events (None, Message attached to Activity boundary, Timer – normal as well as attached to Activity boundary, Timer used in Event Gateways, Cancel attached to an
Activity boundary, Conditional, Signal, Multiple, Link, etc.) and certain types of End Events (None and Terminate), and Gateways. In addition, to enable Choreography within Collaboration it should support Pools and Message Flow.

2.4.3 Visual Appearance

An implementation that creates and displays BPMN Choreography Diagrams SHALL use the graphical elements, shapes and markers as specified in the BPMN specification. The use of text, color, size and lines for Choreography diagram types are listed in Section 7.4.

2.4.4 Choreography Semantics

The tool claiming Choreography Conformance should fully support and interpret the graphical and execution semantics surrounding Choreography diagram elements and Choreography diagram types.

2.4.5 Visual Interchange

The implementation should support import/export of Choreography diagram types and Collaboration diagram types that depict Choreography within collaboration as specified in Section 9.4 to enable portability of Choreography definitions, so that users can take BPMN definitions created in one vendor’s environment and use them in another vendor’s environment.
2.5 Summary of BPMN Conformance Types

Table 2.5 summarizes the requirements for BPMN Conformance.

See Annex C - Glossary.

5 Symbols

There are no symbols defined in this specification.

6 Additional Information

6.1 Conventions

The section introduces the conventions used in this document. This includes (text) notational conventions and notations for schema components. Also included are designated namespace definitions.

6.1.1 Typographical and Linguistic Conventions and Style

This specification incorporates the following conventions:

- The keywords “MUST,” “MUST NOT,” “REQUIRED,” “SHALL,” “MUST NOT,” “SHOULD,” “SHOULD NOT,” “RECOMMENDED,” “MAY,” and “OPTIONAL” in this document are to be interpreted as described in RFC-2119.

- A term is a word or phrase that has a special meaning. When a term is defined, the term name is highlighted in bold typeface.

- A reference to another definition, section, or specification is highlighted with underlined typeface and provides a link to the relevant location in this specification.

- A reference to a graphical element is highlighted with a bold, capitalized word and will be presented with the Arial font (e.g., Sub-Process).

- A reference to a non-graphical element or BPMN concept is highlighted by being italicized and will be presented with the Times New Roman font (e.g., token).

- A reference to an attribute or model association will be presented with the Courier New font (e.g., Expression).

- A reference to a WSBPEL element, attribute, or construct is highlighted with an italic lower-case word, usually preceded by the word “WSBPEL” and will be presented with the Courier New font (e.g., WSBPEL pick).

- Non-normative examples are set off in boxes and accompanied by a brief explanation.
• XML and pseudo code is highlighted with mono-spaced typeface. Different font colors MAY be used to highlight the different components of the XML code.

• The cardinality of any content part is specified using the following operators:
  • <none> — exactly once
  • [0..1] — 0 or 1
  • [0..*] — 0 or more
  • [1..*] — 1 or more

• Attributes separated by | and grouped within { and } — alternative values
  • <value> — default value
  • <type> — the type of the attribute

6.1.2 Abbreviations

The following abbreviations are used throughout this document:

<table>
<thead>
<tr>
<th>This abbreviation</th>
<th>Refers to</th>
</tr>
</thead>
<tbody>
<tr>
<td>WSBPEL</td>
<td>Web Services Business Process Execution Language (see WSBPEL). This abbreviation refers specifically to version 2.0 of the specification.</td>
</tr>
<tr>
<td>WSDL</td>
<td>Web Service Description Language (see WSDL). This abbreviation refers specifically to the W3C Technical Note, 15 March 2001, but is intended to support future versions of the WSDL specification.</td>
</tr>
</tbody>
</table>

6.2 Structure of this Document

Section 7 discusses the scope of the specification and provides a summary of the elements introduced in subsequent sections of the document.

Section 8 introduces the BPMN Core that includes basic BPMN elements needed for constructing various Business Processes, including collaborations, orchestration Processes and Choreographies.

Elements needed for modeling of Collaborations, orchestration Processes, Conversations, and Choreographies are introduced in sections 9, 10, 11 and 12, respectively.

Section 13 introduces the BPMN visual diagram model. Section 14 defines the execution semantics for Process orchestrations in BPMN 2.0. Section 15 discusses a mapping of a BPMN model to WS-BPEL that is derived by analyzing the BPMN objects and the relationships between these objects. Exchange formats and an XSLT transformation between them are provided in Section 16.

7 Overview

There has been much activity in the past few years in developing web service-based XML execution languages for Business Process Management (BPM) systems. Languages such as WSBPEL provide a formal mechanism for the definition of business processes. The key element of such languages is that they are optimized for the operation and inter-operation of BPM Systems. The optimization of these languages for software operations renders them less suited for direct use by humans to design, manage, and monitor Business Processes. WSBPEL has both graph and block structures and utilizes the principles of formal mathematical models, such as pi-calculus. This technical underpinning provides the foundation for business process execution to handle the complex nature of both internal and B2B interactions and take advantage of the benefits of Web services. Given the nature of WSBPEL, a complex Business Process could be organized in a potentially complex, disjointed, and unintuitive format that is handled very well by a software system (or a computer programmer), but would be hard to understand by the business analysts and managers tasked to develop, manage, and monitor the Process. Thus, there is a human level of “inter-operability” or “portability” that is not addressed by these web service-based XML execution languages.

Business people are very comfortable with visualizing Business Processes in a flow-chart format. There are thousands of business analysts studying the way companies work and defining Business Processes with simple flow charts. This creates a technical gap between the format of the initial design of Business Processes and the format of the languages, such as WSBPEL, that will execute these Business Processes. This gap needs to be bridged with a formal mechanism that maps the appropriate visualization of the Business Processes (a notation) to the appropriate execution format (a BPM execution language) for these Business Processes.

Inter-operation of Business Processes at the human level, rather than the software engine level, can be solved with standardization of the Business Process Model and Notation (BPMN). BPMN provides a multiple diagrams, which are designed for use by the people who design and manage Business Processes. BPMN also provides a mapping to an execution language of BPM Systems (WSBPEL). Thus, BPMN would provide a standard visualization mechanism for Business Processes defined in an execution optimized business process language.

BPMN provides businesses with the capability of understanding their internal business procedures in a graphical notation and will give organizations the ability to communicate these procedures in a standard manner. Currently, there are scores of Process modeling tools and methodologies. Given that individuals will move from one company to another and that companies will merge and diverge, it is likely that business analysts need to understand multiple representations of Business Processes—potentially different representations of the same Process as it moves through its lifecycle of development, implementation, execution, monitoring, and analysis. Therefore, a standard graphical notation will facilitate the understanding of the performance Collaborations and business transactions within and between the organizations. This will ensure that businesses will understand themselves and participants in their business and will enable organizations to adjust to new internal and B2B business circumstances quickly. BPMN follows the tradition of flowcharting notations for readability and flexibility. In addition, the BPMN execution semantics is fully formalized. The OMG is using the experience of the business process notations that have preceded BPMN to create the next generation notation that combines readability, flexibility, and expandability.

BPMN will also advance the capabilities of traditional business process notations by inherently handling B2B Business Process concepts, such as public and private Processes and Choreographies, as well as advanced modeling concepts, such as exception handling, transactions, and compensation.

7.1 BPMN Scope

This specification provides a notation and model for Business Processes and an interchange format that can be used to exchange BPMN Process definitions (both domain model and diagram layout) between different tools. The goal of the specification is to enable portability of Process definitions, so that users can take Process definitions created in one vendor’s environment and use them in another vendor’s environment.

The BPMN 2.0 specification extends the scope and capabilities of the BPMN 1.2 in several areas:

- Formalizes the execution semantics for all BPMN elements
- Defines an extensibility mechanism for both Process model extensions and graphical extensions
- Refines Event composition and correlation
- Extends the definition of human interactions
- Defines a Choreography model

This specification also resolves known BPMN 1.2 inconsistencies and ambiguities.

BPMN is constrained to support only the concepts of modeling that are applicable to Business Processes. This means that other types of modeling done by organizations for business purposes is out of scope for BPMN. Therefore, the following are aspects that are out of the scope of this specification:

- Definition of organizational models and resources
- Modeling of functional breakdowns
- Data and information models
- Modeling of strategy
- Business rules models

Since these types of high-level modeling either directly or indirectly affects Business Processes, the relationships between BPMN and other high-level business modeling can be defined more formally as BPMN and other specifications are advanced.

While BPMN shows the flow of data (Messages), and the association of data artifacts to Activities, it is not a data flow language. In addition, operational simulation, monitoring and deployment of Business Processes are out of scope of this specification.

BPMN 2.0 can be mapped to more than one platform dependent process modeling language, e.g. WS-BPEL 2.0. This document includes a mapping of a subset of BPMN to WS-BPEL 2.0. Mappings to other emerging standards are considered to be separate efforts.

The specification utilizes other standards for defining data types, Expressions and service operations. These standards are XML Schema, XPath, and WSDL, respectively.
7.1.1 Uses of BPMN

Business Process modeling is used to communicate a wide variety of information to a wide variety of audiences. BPMN is designed to cover many types of modeling and allows the creation of end-to-end Business Processes. The structural elements of BPMN allow the viewer to be able to easily differentiate between sections of a BPMN Diagram. There are three basic types of sub-models within an end-to-end BPMN model:

- **Processes** (Orchestration), including:
  - *Private non-executable* (internal) Business Processes
  - *Private executable* (internal) Business Processes
  - Public Processes
- Choreographies
- Collaborations, which can include Processes and/or Choreographies
  - A view of Conversations

Private (Internal) Business Processes

Private Business Processes are those internal to a specific organization. These Processes have been generally called workflow or BPM Processes (see Figure 10.4). Another synonym typically used in the Web services area is the Orchestration of services. There are two (2) types of private Processes: executable and non-executable. An executable Process is a Process that has been modeled for the purpose of being executed according to the semantics defined in Chapter 14. Of course, during the development cycle of the Process, there will be stages where the Process does not have enough detail to be “executable.” A non-executable Process is a private Process that has been modeled for the purpose of documenting Process behavior at a modeler-defined level of detail. Thus, information needed for execution, such as formal condition Expressions are typically not included in a non-executable Process.

If a swimlanes-like notation is used (e.g., a Collaboration, see below) then a private Business Process will be contained within a single Pool. The Process flow is therefore contained within the Pool and cannot cross the boundaries of the Pool. The flow of Messages can cross the Pool boundary to show the interactions that exist between separate private Business Processes.

![Figure 7.1 - Example of a private Business Process](image)

Public Processes

A public Process represents the interactions between a private Business Process and another Process or Participant (see Figure 7.2). Only those Activities that are used to communicate to the other Participant(s) are included in the public Process. All other “internal” Activities of the private Business Process are not shown in the public Process. Thus, the public Process shows to the outside world the Message Flows and the order of those Message Flows that are needed to interact with that Process. Public Processes can be modeled separately or within a Collaboration to show the flow of Messages between the public Process Activities and other Participants. Note that the public type of Process was named “abstract” in BPMN 1.2.
Collaborations

A **Collaboration** depicts the interactions between two or more business entities. A **Collaboration** usually contains two (2) or more **Pools**, representing the **Participants** in the **Collaboration**. The **Message** exchange between the **Participants** is shown by a **Message Flow** that connects two (2) **Pools** (or the objects within the **Pools**). The **Messages** associated with the **Message Flows** can also be shown. The **Collaboration** can be shown as two or more **public Processes** communicating with each other (see Figure 7.3). With a **public Process**, the **Activities** for the **Collaboration** participants can be considered the “touch-points” between the participants. The corresponding internal (executable) **Processes** are likely to have much more **Activity** and detail than what is shown in the **public Processes**. Or a **Pool** MAY be empty, a “black box.” **Choreographies** MAY be shown “in between” the **Pools** as they bisect the **Message Flows** between the **Pools**. All combinations of **Pools, Processes**, and a **Choreography** are allowed in a **Collaboration**. 

---

- **I feel sick**
- **I want to see doctor**
- **Here is your medicine**
- **Go see doctor**

---

**Business Process Model and Notation, v2.0**
Figure 7.3 - An example of a Collaborative Process

Choreographies

A self-contained **Choreography** (no **Pools** or **Orchestration**) is a definition of the expected behavior, basically a procedural contract, between interacting **Participants**. While a normal **Process** exists within a **Pool**, a **Choreography** exists between **Pools** (or **Participants**).

The **Choreography** looks similar to a **private Business Process** since it consists of a network of **Activities**, **Events**, and **Gateways** (see Figure 7.4). However, a **Choreography** is different in that the **Activities** are interactions that represent a set (1 or more) of **Message** exchanges, which involves two (2) or more **Participants**. In addition, unlike a normal **Process**, there is no central controller, responsible entity or observer of the **Process**.

Figure 7.4 - An example of a Choreography
Conversations

The Conversation diagram is a particular usage of and an informal description of a Collaboration diagram. However, the Pools of a Conversation usually do not contain a Process and a Choreography is usually not placed in between the Pools of a Conversation diagram. A Conversation is the logical relation of Message exchanges. The logical relation, in practice, often concerns a business object(s) of interest, e.g., “Order,” “Shipment and Delivery,” or “Invoice.”

Message exchanges are related to each other and reflect distinct business scenarios. For example, in logistics, stock replenishments involve the following types scenarios: creation of sales orders; assignment of carriers for shipments combining different sales orders; crossing customs/quarantine; processing payment and investigating exceptions. Thus, a Conversation diagram, as shown in Figure 7.5, shows Conversations (as hexagons) between Participants (Pools). This provides a “bird’s eye” perspective of the different Conversations which relate to the domain.

![Conversation Diagram](image)

Figure 7.5 - An example of a Conversation diagram

Diagram Point of View

Since a BPMN Diagram MAY depict the Processes of different Participants, each Participant could view the Diagram differently. That is, the Participants have different points of view regarding how the Processes will apply to them. Some of the Activities will be internal to the Participant (meaning performed by or under control of the Participant) and other
Activities will be external to the Participant. Each Participant will have a different perspective as to which are internal and external. At runtime, the difference between internal and external Activities is important in how a Participant can view the status of the Activities or trouble-shoot any problems. However, the Diagram itself remains the same. Figure 7.3 displays a Business Process that has two points of view. One point of view is of a Patient, the other is of the Doctor’s office. The Diagram shows the Activities of both participants in the Process, but when the Process is actually being performed, each Participant will only have control over their own Activities. Although the Diagram point of view is important for a viewer of the Diagram to understand how the behavior of the Process will relate to that viewer, BPMN will not currently specify any graphical mechanisms to highlight the point of view. It is open to the modeler or modeling tool vendor to provide any visual cues to emphasize this characteristic of a Diagram.

Understanding the Behavior of Diagrams

Throughout this document, we discuss how Sequence Flows are used within a Process. To facilitate this discussion, we employ the concept of a token that will traverse the Sequence Flows and pass through the elements in the Process. A token is a theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it “traverses” the structure of the Process. However, modeling and execution tools that implement BPMN are NOT REQUIRED to implement any form of token.

A Start Event generates a token that MUST eventually be consumed at an End Event (which MAY be implicit if not graphically displayed). The path of tokens should be traceable through the network of Sequence Flows, Gateways, and Activities within a Process.

Note – A token does not traverse a Message Flow since it is a Message that is passed down a Message Flow (as the name implies).

7.2 BPMN Elements

It should be emphasized that one of the drivers for the development of BPMN is to create a simple and understandable mechanism for creating Business Process models, while at the same time being able to handle the complexity inherent to Business Processes. The approach taken to handle these two conflicting requirements was to organize the graphical aspects of the notation into specific categories. This provides a small set of notation categories so that the reader of a BPMN diagram can easily recognize the basic types of elements and understand the diagram. Within the basic categories of elements, additional variation and information can be added to support the requirements for complexity without dramatically changing the basic look and feel of the diagram. The five (5) basic categories of elements are:

- Flow Objects
- Data
- Connecting Objects
- Swimlanes
- Artifacts

Flow Objects are the main graphical elements to define the behavior of a Business Process. There are three (3) Flow Objects:

- Events
- Activities
• Gateways

Data is represented with the four (4) elements:
  • Data Objects
  • Data Inputs
  • Data Outputs
  • Data Stores

There are four (4) ways of connecting the Flow Objects to each other or other information. There are four (4) Connecting Objects:
  • Sequence Flows
  • Message Flows
  • Associations
  • Data Associations

There are two (2) ways of grouping the primary modeling elements through “Swimlanes:”
  • Pools
  • Lanes

Artifacts are used to provide additional information about the Process. There are two (2) standardized Artifacts, but modelers or modeling tools are free to add as many Artifacts as necessary. There could be additional BPMN efforts to standardize a larger set of Artifacts for general use or for vertical markets. The current set of Artifacts includes:
  • Group
  • Text Annotation

### 7.2.1 Basic BPMN Modeling Elements

Table 7.1 displays a list of the basic modeling elements that are depicted by the notation.
Table 7.1 - Basic Modeling Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Notation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>An Event is something that “happens” during the course of a Process (see page 245) or a Choreography (see page 350). These Events affect the flow of the model and usually have a cause (<em>trigger</em>) or an impact (<em>result</em>). Events are circles with open centers to allow internal markers to differentiate different <em>triggers</em> or <em>results</em>. There are three types of Events, based on when they affect the flow: Start, Intermediate, and End.</td>
<td><img src="image" alt="Event" /></td>
</tr>
<tr>
<td>Activity</td>
<td>An Activity is a generic term for work that company performs (see page 155) in a Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process Model are: Sub-Process and Task, which are rounded rectangles. Activities are used in both standard Processes and in Choreographies.</td>
<td><img src="image" alt="Activity" /></td>
</tr>
<tr>
<td>Gateway</td>
<td>A Gateway is used to control the divergence and convergence of Sequence Flows in a Process (see page 149) and in a Choreography (see page 355). Thus, it will determine branching, forking, merging, and joining of paths. Internal markers will indicate the type of behavior control.</td>
<td><img src="image" alt="Gateway" /></td>
</tr>
<tr>
<td>Sequence Flow</td>
<td>A Sequence Flow is used to show the order that Activities will be performed in a Process (see page 97) and in a Choreography (see page 330).</td>
<td><img src="image" alt="Sequence Flow" /></td>
</tr>
<tr>
<td>Message Flow</td>
<td>A Message Flow is used to show the flow of Messages between two <em>Participants</em> that are prepared to send and receive them (see page 121). In BPMN, two separate Pools in a Collaboration Diagram will represent the two <em>Participants</em> (e.g., PartnerEntities and/or PartnerRoles).</td>
<td><img src="image" alt="Message Flow" /></td>
</tr>
<tr>
<td>Association</td>
<td>An Association is used to link information and Artifacts with BPMN graphical elements (see page 67). Text Annotations (see page 72) and other Artifacts (see page 66) can be Associated with the graphical elements. An arrowhead on the Association indicates a direction of flow (e.g., data), when appropriate.</td>
<td><img src="image" alt="Association" /></td>
</tr>
<tr>
<td>Pool</td>
<td>A Pool is the graphical representation of a <em>Participant</em> in a Collaboration (see page 112). It also acts as a “swimlane” and a graphical container for partitioning a set of Activities from other Pools, usually in the context of B2B situations. A Pool MAY have internal details, in the form of the Process that will be executed. Or a Pool MAY have no internal details, i.e., it can be a &quot;black box.&quot;</td>
<td><img src="image" alt="Pool" /></td>
</tr>
</tbody>
</table>
### 7.2.2 Extended BPMN Modeling Elements

Table 7.2 displays a more extensive list of the Business Process concepts that could be depicted through a business process modeling notation.

30 Business Process Model and Notation, v2.0
### Event

An Event is something that “happens” during the course of a Process (see page 245) or a Choreography (see page 350). These Events affect the flow of the model and usually have a cause (Trigger) or an impact (Result). Events are circles with open centers to allow internal markers to differentiate different Triggers or Results. There are three types of Events, based on when they affect the flow: Start, Intermediate, and End.

#### Flow Dimension (e.g., Start, Intermediate, End)

<table>
<thead>
<tr>
<th>Start</th>
<th>Intermediate</th>
<th>End</th>
</tr>
</thead>
<tbody>
<tr>
<td>As the name implies, the Start Event indicates where a particular Process (see page 245) or Choreography (see page 350) will start.</td>
<td>Intermediate Events occur between a Start Event and an End Event. They will affect the flow of the Process (see page 257) or Choreography (see page 350), but will not start or (directly) terminate the Process.</td>
<td>As the name implies, the End Event indicates where a Process (see page 253) or Choreography (see page 354) will end.</td>
</tr>
</tbody>
</table>

#### Type Dimension (e.g., None, Message, Timer, Error, Cancel, Compensation, Conditional, Link, Signal, Multiple, Terminate.)

The Start and some Intermediate Events have “triggers” that define the cause for the Event (see section entitled “Start Event” on page 245 and section entitled “Intermediate Event” on page 257). There are multiple ways that these events can be triggered. End Events MAY define a “result” that is a consequence of a Sequence Flow path ending. Start Events can only react to (“catch”) a trigger. End Events can only create (“throw”) a result. Intermediate Events can catch or throw triggers. For the Events, triggers that catch, the markers are unfilled, and for triggers and results that throw, the markers are filled.

Additionally, some Events, which were used to interrupt Activities in BPMN 1.1, can now be used in a mode that does not interrupt. The boundary of these Events is dashed (see figure to the right).

**Note:** The symbols and their meanings are shown in the table with their respective categories.
### Table 7.2 - BPMN Extended Modeling Elements

<table>
<thead>
<tr>
<th>Activity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity</td>
<td>An Activity is a generic term for work that company performs (see page 155) in a Process. An Activity can be atomic or non-atomic (compound). The types of Activities that are a part of a Process Model are: Sub-Process and Task, which are rounded rectangles. Activities are used in both standard Processes and in Choreographies.</td>
</tr>
</tbody>
</table>

| Task (Atomic) | A Task is an atomic Activity that is included within a Process (see page 160). A Task is used when the work in the Process is not broken down to a finer level of Process detail. |

| Choreography Task | A Choreography Task is an atomic Activity in a Choreography (see page 333). It represents a set of one (1) or more Message exchanges. Each Choreography Task involves two (2) Participants. The name of the Choreography Task and each of the Participants are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) or more Participant Bands and one Task Name Band. |

| Process/Sub-Process (non-atomic) | A Sub-Process is a compound Activity that is included within a Process (see page 178) or Choreography (see page 338). It is compound in that it can be broken down into a finer level of detail (a Process or Choreography) through a set of sub-Activities. See Next Four (4) Figures |

| Collapsed Sub-Process | The details of the Sub-Process are not visible in the Diagram (see page 178). A “plus” sign in the lower-center of the shape indicates that the Activity is a Sub-Process and has a lower-level of detail. |

| Expanded Sub-Process | The boundary of the Sub-Process is expanded and the details (a Process) are visible within its boundary (see page 178). Note that Sequence Flows cannot cross the boundary of a Sub-Process. |
### Table 7.2 - BPMN Extended Modeling Elements

<table>
<thead>
<tr>
<th>Collapsed Sub-Choreography</th>
<th>The details of the Sub-Choreography are not visible in the Diagram (see page 338). A “plus” sign in the lower-center of the Task Name Band of the shape indicates that the Activity is a Sub-Process and has a lower-level of detail.</th>
</tr>
</thead>
</table>
| Expanded Sub-Choreography | The boundary of the Sub-Choreography is expanded and the details (a Choreography) are visible within its boundary (see page 338)  
   
   Note that Sequence Flows cannot cross the boundary of a Sub-Choreography. |
| Gateway | A Gateway is used to control the divergence and convergence of Sequence Flows in a Process (see page 295) and in a Choreography (see page 355). Thus, it will determine branching, forking, merging, and joining of paths. Internal markers will indicate the type of behavior control (see below). |
| Gateway Control Types | Icons within the diamond shape of the Gateway will indicate the type of flow control behavior. The types of control include:  
   
   • Exclusive decision and merging. Both Exclusive (see page 298) and Event-Based (see page 305) perform exclusive decisions and merging. Exclusive can be shown with or without the “X” marker.  
   
   • Event-Based and Parallel Event-based gateways can start a new instance of the Process.  
   
   • Inclusive Gateway decision and merging (see page 300)  
   
   • Complex Gateway -- complex conditions and situations (e.g., 3 out of 5; page 303)  
   
   • Parallel Gateway forking and joining (see page 301)  
   
   Each type of control affects both the incoming and outgoing flow. |

**Table 7.2 - BPMN Extended Modeling Elements**

<table>
<thead>
<tr>
<th>Sequence Flow</th>
<th>A Sequence Flow is used to show the order that Activities will be performed in a Process (see page 97) and in a Choreography (see page 330).</th>
<th>See next seven figures</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal Flow</td>
<td><em>Normal flow</em> refers to paths of Sequence Flow that do not start from an Intermediate Event attached to the boundary of an Activity.</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
<tr>
<td>Uncontrolled flow</td>
<td><em>Uncontrolled flow</em> refers to flow that is not affected by any conditions or does not pass through a Gateway. The simplest example of this is a single Sequence Flow connecting two Activities. This can also apply to multiple Sequence Flows that converge to or diverge from an Activity. For each uncontrolled Sequence Flows a <em>token</em> will flow from the source object through the Sequence Flows to the target object.</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
<tr>
<td>Conditional flow</td>
<td>A Sequence Flow can have a condition <em>Expression</em> that are evaluated at runtime to determine whether or not the Sequence Flow will be used (i.e., will a <em>token</em> travel down the Sequence Flow – see page 97). If the <em>conditional flow</em> is outgoing from an Activity, then the Sequence Flow will have a mini-diamond at the beginning of the connector (see figure to the right). If the <em>conditional flow</em> is outgoing from a Gateway, then the line will not have a mini-diamond (see figure in the row above).</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
<tr>
<td>Default flow</td>
<td>For Data-Based Exclusive Gateways or Inclusive Gateways, one type of flow is the Default <em>condition flow</em> (see page 97). This flow will be used only if all the other outgoing <em>conditional flow</em> is not <em>true</em> at runtime. These Sequence Flows will have a diagonal slash will be added to the beginning of the connector (see the figure to the right).</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
<tr>
<td>Exception Flow</td>
<td><em>Exception flow</em> occurs outside the <em>normal flow</em> of the Process and is based upon an Intermediate Event attached to the boundary of an Activity that occurs during the performance of the Process (see page 295).</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
<tr>
<td>Table 7.2 - BPMN Extended Modeling Elements</td>
<td></td>
<td></td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Message Flow</strong></td>
<td>A Message Flow is used to show the flow of Messages between two Participants that are prepared to send and receive them (see page 121). In BPMN, two separate Pools in a Collaboration Diagram will represent the two Participants (e.g., PartnerEntities and/or PartnerRoles).</td>
<td></td>
</tr>
<tr>
<td><strong>Compensation Association</strong></td>
<td>Compensation Association occurs outside the normal flow of the Process and is based upon a Compensation Intermediate Event that is triggered through the failure of a transaction or a throw Compensation Event (see page 311). The target of the Association MUST be marked as a Compensation Activity.</td>
<td></td>
</tr>
<tr>
<td><strong>Data Object</strong></td>
<td>Data Objects provide information about what Activities require to be performed and/or what they produce (see page 212), Data Objects can represent a singular object or a collection of objects. Data Input and Data Output provide the same information for Processes.</td>
<td></td>
</tr>
<tr>
<td><strong>Message</strong></td>
<td>A Message is used to depict the contents of a communication between two Participants (as defined by a business PartnerRole or a business PartnerEntity—see on page 93).</td>
<td></td>
</tr>
</tbody>
</table>
Fork

BPMN uses the term “fork” to refer to the dividing of a path into two or more parallel paths (also known as an AND-Split). It is a place in the Process where activities can be performed concurrently, rather than sequentially.

There are two options:

- Multiple Outgoing Sequence Flows can be used (see figure top-right). This represents “uncontrolled” flow is the preferred method for most situations.
- A Parallel Gateway can be used (see figure bottom-right). This will be used rarely, usually in combination with other Gateways.

Join

BPMN uses the term “join” to refer to the combining of two or more parallel paths into one path (also known as an AND-Join or synchronization).

A Parallel Gateway is used to show the joining of multiple Sequence Flows.

Decision, Branching Point

Decisions are Gateways within a Process (see page 295) or a Choreography (see page 355) where the flow of control can take one or more alternative paths.

Exclusive

This Decision represents a branching point where Alternatives are based on conditional Expressions contained within the outgoing Sequence Flows (see page 298 or page 355). Only one of the Alternatives will be chosen.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
### Table 7.2 - BPMN Extended Modeling Elements

| Event-Based | This Decision represents a branching point where Alternatives are based on an Event that occurs at that point in the Process (see page 305) or Choreography (see page 360). The specific Event, usually the receipt of a Message, determines which of the paths will be taken. Other types of Events can be used, such as Timer. Only one of the Alternatives will be chosen.

There are two options for receiving Messages:
- Tasks of Type Receive can be used (see figure top-right).
- Intermediate Events of Type Message can be used (see figure bottom-right). |

| Inclusive | This Decision represents a branching point where Alternatives are based on conditional Expressions contained within the outgoing Sequence Flows (see page 300). In some sense it is a grouping of related independent Binary (Yes/No) Decisions. Since each path is independent, all combinations of the paths MAY be taken, from zero to all. However, it should be designed so that at least one path is taken. A Default Condition could be used to ensure that at least one path is taken.

There are two versions of this type of Decision:
- The first uses a collection of conditional Sequence Flows, marked with mini-diamonds (see top-right figure).
- The second uses an Inclusive Gateway (see bottom-right picture). |
Merging | BPMN uses the term “merge” to refer to the exclusive combining of two or more paths into one path (also known as an OR-Join). A Merging Exclusive Gateway is used to show the merging of multiple Sequence Flows (see upper figure to the right). If all the incoming flow is alternative, then a Gateway is not needed. That is, uncontrolled flow provides the same behavior (see lower figure to the right).

| Looping | BPMN provides 2 (two) mechanisms for looping within a Process.

| Activity Looping | The attributes of Tasks and Sub-Processes will determine if they are repeated or performed once (see page 197). There are two types of loops: Standard and Multi-Instance. A small looping indicator will be displayed at the bottom-center of the activity.

| Sequence Flow Looping | Loops can be created by connecting a Sequence Flow to an “upstream” object. An object is considered to be upstream if that object has an outgoing Sequence Flow that leads to a series of other Sequence Flows, the last of which is an incoming Sequence Flow for the original object.

### Table 7.2 - BPMN Extended Modeling Elements

| Nested/Embedded Sub-Process (Inline Block) | A nested (or embedded) Sub-Process is an activity that shares the same set of data as its parent process (see page 178). This is opposed to a Sub-Process that is independent, re-usable, and referenced from the parent process. Data needs to be passed to the referenced Sub-Process, but not to the nested Sub-Process. | There is no special indicator for nested Sub-Processes |
| Group (a box around a group of objects within the same category) | A Group is a grouping of graphical elements that are within the same Category (see page 69). This type of grouping does not affect the Sequence Flows within the Group. The Category name appears on the diagram as the group label. Categories can be used for documentation or analysis purposes. Groups are one way in which Categories of objects can be visually displayed on the diagram. | |
| Off-Page Connector | Generally used for printing, this object will show where a Sequence Flow leaves one page and then restarts on the next page. A Link Intermediate Event can be used as an Off-Page Connector. | |
| Association | An Association is used to link information and Artifacts with BPMN graphical elements (see page 67). Text Annotations (see page 72) and other Artifacts (see page 66) can be Associated with the graphical elements. An arrowhead on the Association indicates a direction of flow (e.g., data), when appropriate. | |
| Text Annotation (attached with an Association) | Text Annotations are a mechanism for a modeler to provide additional text information for the reader of a BPMN Diagram (see page 72). | |
| Pool | A Pool is the graphical representation of a Participant in a Collaboration (see page 112). It also acts as a “swimlane” and a graphical container for partitioning a set of Activities from other Pools, usually in the context of B2B situations. A Pool MAY have internal details, in the form of the Process that will be executed. Or a Pool MAY have no internal details, i.e., it can be a "black box." | |
7.3 BPMN Diagram Types

The BPMN 2.0 aims to cover three basic models of Processes: private Processes (both executable and non-executable), public Processes, and Choreographies. Within and between these three BPMN sub-models, many types of Diagrams can be created. The following are examples of Business Processes that can be modeled using BPMN 2.0:

- High-level non-executable Process Activities (not functional breakdown)
- Detailed executable Business Process
- As-is or old Business Process
- To-be or new Business Process
- A description of expected behavior between two (2) or more business Participants—a Choreography.
- Detailed private Business Process (either executable or non-executable) with interactions to one or more external Entities (or “Black Box” Processes)
- Two or more detailed executable Processes interacting
- Detailed executable Business Process relationship to a Choreography
- Two or more public Processes
- Public Process relationship to Choreography
- Two or more detailed executable Business Processes interacting through a Choreography

BPMN is designed to allow describing all above examples of Business Processes. However, the ways that different sub-models are combined is left to tool vendors. A BPMN 2.0 compliant implementation could RECOMMEND that modelers pick a focused purpose, such as a private Process, or Choreographies. However, the BPMN 2.0 specification makes no assumptions.

7.4 Use of Text, Color, Size, and Lines in a Diagram

Text Annotation objects can be used by the modeler to display additional information about a Process or attributes of the objects within a BPMN Diagram.

- BPMN elements (e.g. Flow objects) MAY have labels (e.g., its name and/or other attributes) placed inside the shape, or above or below the shape, in any direction or location, depending on the preference of the modeler or modeling tool vendor.
- The fills that are used for the graphical elements MAY be white or clear.
- The notation MAY be extended to use other fill colors to suit the purpose of the modeler or tool (e.g., to highlight the value of an object attribute). However,
  - The markers for “throwing” Events MUST have a dark fill (see “End Event” on page 253 and “Intermediate
Event” on page 257 for more details).

- Participant Bands for Choreography Tasks and Sub-Choreographies that are not the initiator of the Activity MUST have a light fill (see “Choreography Task” on page 333 and “Sub-Choreography” on page 338 for more details).

- Flow objects and markers MAY be of any size that suits the purposes of the modeler or modeling tool.

- The lines that are used to draw the graphical elements MAY be black.

- The notation MAY be extended to use other line colors to suit the purpose of the modeler or tool (e.g., to highlight the value of an object attribute).

- The notation MAY be extended to use other line styles to suit the purpose of the modeler or tool (e.g., to highlight the value of an object attribute) with the condition that the line style MUST NOT conflict with any current BPMN defined line style. Thus, the line styles of Sequence Flows, Message Flows, and Text Associations MUST NOT be modified or duplicated.

7.5 **Flow Object Connection Rules**

An incoming Sequence Flow can connect to any location on a Flow Object (left, right, top, or bottom). Likewise, an outgoing Sequence Flow can connect from any location on a Flow Object (left, right, top, or bottom). A Message Flow also has this capability. BPMN allows this flexibility; however, we also RECOMMEND that modelers use judgment or best practices in how Flow Objects should be connected so that readers of the Diagrams will find the behavior clear and easy to follow. This is even more important when a Diagram contains Sequence Flows and Message Flows. In these situations it is best to pick a direction of Sequence Flows, either left to right or top to bottom, and then direct the Message Flows at a 90° angle to the Sequence Flows. The resulting Diagrams will be much easier to understand.

7.5.1 **Sequence Flow Connections Rules**

Table 7.3 displays the BPMN Flow Objects and shows how these objects can connect to one another through Sequence Flows. These rules apply to the connections within a Process Diagram and within a Choreography Diagram. The symbol indicates that the object listed in the row can connect to the object listed in the column. The quantity of connections into and out of an object is subject to various configuration dependencies are not specified here. Refer to the sections in the next chapter for each individual object for more detailed information on the appropriate connection rules. Note that if a Sub-Process has been expanded within a Diagram, the objects within the Sub-Process cannot be connected to objects outside of the Sub-Process. Nor can Sequence Flows cross a Pool boundary.

<table>
<thead>
<tr>
<th>From \ To</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>%</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Only those objects that can have incoming and/or outgoing Sequence Flows are shown in the table. Thus, Pool, Lane, Data Object, Group, and Text Annotation are not listed in the table. Also, the Activity shapes in the table represent Activities and Sub-Processes for Processes, and Choreography Activities and Sub-Choreographies for Choreography.

### 7.5.2 Message Flow Connection Rules

Table 7.4 displays the BPMN modeling objects and shows how these objects can connect to one another through Message Flows. These rules apply to the connections within a Collaboration Diagram. The symbol indicates that the object listed in the row can connect to the object listed in the column. The quantity of connections into and out of an object is subject to various configuration dependencies are not specified here. Refer to the sections in the next chapter for each individual object for more detailed information on the appropriate connection rules. Note that Message Flows cannot connect to objects that are within the same Pool.
Only those objects that can have incoming and/or outgoing Message Flows are shown in the table. Thus, Lane, Gateway, Data Object, Group, and Text Annotation are not listed in the table.

### 7.6 BPMN Extensibility

BPMN 2.0 introduces an extensibility mechanism that allows extending standard BPMN elements with additional attributes. It can be used by modelers and modeling tools to add non-standard elements or Artifacts to satisfy a specific need, such as the unique requirements of a vertical domain, and still have valid BPMN Core. Extension attributes MUST NOT contradict the semantics of any BPMN element. In addition, while extensible, BPMN Diagrams should still have the basic look-and-feel so that a Diagram by any modeler should be easily understood by any viewer of the Diagram. Thus the footprint of the basic flow elements (Events, Activities, and Gateways) MUST NOT be altered.
The specification differentiates between mandatory and optional extensions (Section 8.2.3 explains the syntax used to declare extensions). If a mandatory extension is used, a compliant implementation MUST understand the extension. If an optional extension is used, a compliant implementation MAY ignore the extension.

### 7.7 BPMN Example

The following is an example of a manufacturing process from different perspectives.

![Collaboration diagram with black-box Pools](image)

**Figure 7.6 - An example of a Collaboration diagram with black-box Pools**
Figure 7.7 - An example of a stand-alone Choreography diagram
Figure 7.8 - An example of a stand-alone Process (Orchestration) diagram
8 BPMN Core Structure

Note – The content of this chapter is REQUIRED for all BPMN conformance types. For more information about BPMN conformance types, see page 2.

The proposed technical structuring of BPMN is based on the concept of extensibility layers on top of a basic series of simple elements identified as Core Elements of the specification. From this core set of constructs, layering is used to describe additional elements of the specification that extend and add new constructs to the specification and relies on clear dependency paths for resolution. The XML Schema model lends itself particularly well to the proposed structuring model with formalized import and resolution mechanics that remove ambiguities in the definitions of elements in the outer layers of the specification.

Figure 8.1 - A representation of the BPMN Core and Layer Structure

Figure 8.1 shows the basic principles of layering that can be composed in well defined ways. The approach uses formalization constructs for extensibility that are applied consistently to the definition.

The additional effect of layering is that compatibility layers can be built, allowing for different levels of compliance amongst vendors, and also enabling vendors to add their own layers in support of different vertical industries or target audiences. In addition, it provides mechanism for the redefinition of previously existing concepts without affecting backwards compatibility, but defining two or more non-composable layers, the level of compliance with the specification and backwards compatibility can be achieved without compromising clarity.

The BPMN specification is structured in layers, where each layer builds on top of and extends lower layers. Included is a Core or kernel which includes the most fundamental elements of BPMN that are REQUIRED for constructing BPMN diagrams: Process, Choreography, and Collaboration. The Core is intended to be simple, concise, and extendable, with well defined behavior.
The Core contains three (3) sub-packages (see Figure 8.2):

- **Foundation**: The fundamental constructs needed for BPMN modeling.
- **Service**: The fundamental constructs needed for modeling services and interfaces.
- **Common**: Those classes which are common to the layers of **Process**, **Choreography**, and **Collaboration**.

![Figure 8.2 - Class diagram showing the core packages](image)

Figure 8.2 displays the organization of the main set of BPMN core model elements.
Figure 8.3 - Class diagram showing the organization of the core BPMN elements

8.1 Infrastructure

The BPMN Infrastructure package contains two (2) elements that are used for both abstract syntax models and diagram models.

8.1.1 Definitions

The Definitions class is the outermost containing object for all BPMN elements. It defines the scope of visibility and the namespace for all contained elements. The interchange of BPMN files will always be through one or more Definitions.
Figure 8.4 - Definitions class diagram

The Definitions element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.1 presents the additional attributes and model associations of the Definitions element:
## Table 8.1 - Definitions attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The name of the Definition.</td>
</tr>
<tr>
<td>targetNamespace: string</td>
<td>This attribute identifies the namespace associated with the Definition and follows the convention established by XML Schema.</td>
</tr>
<tr>
<td>expressionLanguage: string [0..1]</td>
<td>This attribute identifies the formal Expression language used in Expressions within the elements of this Definition. The Default is “<a href="http://www.w3.org/1999/XPath%E2%80%9D">http://www.w3.org/1999/XPath”</a>. This value MAY be overridden on each individual formal Expression. The language MUST be specified in a URI format.</td>
</tr>
<tr>
<td>typeLanguage: string [0..1]</td>
<td>This attribute identifies the type system used by the elements of this Definition. Defaults to <a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a>. This value can be overridden on each individual ItemDefinitionSchema. The language MUST be specified in a URI format.</td>
</tr>
<tr>
<td>rootElements: RootElement [0..*]</td>
<td>This attribute lists the root elements that are at the root of this Definitions. These elements can be referenced within this Definitions and are visible to other Definitions.</td>
</tr>
<tr>
<td>diagrams: BPMNDiagram [0..*]</td>
<td>This attribute lists the BPMNDiagrams that are contained within this Definitions (see page 377 for more information on BPMNDiagrams).</td>
</tr>
<tr>
<td>imports: Import [0..*]</td>
<td>This attribute is used to import externally defined elements and make them available for use by elements within this Definitions.</td>
</tr>
<tr>
<td>extensions: Extension [0..*]</td>
<td>This attribute identifies extensions beyond the attributes and model associations in the base BPMN specification. See page 57 for additional information on extensibility.</td>
</tr>
<tr>
<td>relationships: Relationship [0..*]</td>
<td>This attribute enables the extension and integration of BPMN models into larger system/development Processes.</td>
</tr>
<tr>
<td>exporter: string [0..1]</td>
<td>This attribute identifies the tool that is exporting the bpmn model file.</td>
</tr>
<tr>
<td>exporterVersion: string [0..1]</td>
<td>This attribute identifies the version of the tool that is exporting the bpmn model file.</td>
</tr>
</tbody>
</table>

### 8.1.2 Import

The **Import** class is used when referencing external element, either **BPMN** elements contained in other **BPMN** Definitions or non-**BPMN** elements. **Imports** MUST be explicitly defined.

Table 8.2 presents the attributes of **Import**.
Table 8.2 – Import attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>importType: string</td>
<td>Identifies the type of document being imported by providing an absolute URI that identifies the encoding language used in the document. The value of the importType attribute MUST be set to <a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a> when importing XML Schema 1.0 documents, to <a href="http://www.w3.org/TR/wsd120/">http://www.w3.org/TR/wsd120/</a> when importing WSDL 2.0 documents, and <a href="http://www.omg.org/spec/BPMN/20100524/MODEL">http://www.omg.org/spec/BPMN/20100524/MODEL</a> when importing BPMN 2.0 documents. Other types of documents MAY be supported. Importing Xml Schema 1.0, WSDL 2.0 and BPMN 2.0 types MUST be supported.</td>
</tr>
<tr>
<td>location: string [0..1]</td>
<td>Identifies the location of the imported element.</td>
</tr>
<tr>
<td>namespace: string</td>
<td>Identifies the namespace of the imported element.</td>
</tr>
</tbody>
</table>

8.1.3 Infrastructure Package XML Schemas

Table 8.3 – Definitions XML schema

```xml
<xsd:element name="definitions" type="tDefinitions"/>
<xsd:complexType name="tDefinitions">
  <xsd:sequence>
    <xsd:element ref="import" minOccurs="0" maxOccurs="unbounded"/>
    <xsd:element ref="extension" minOccurs="0" maxOccurs="unbounded"/>
    <xsd:element ref="RootElement" minOccurs="0" maxOccurs="unbounded"/>
    <xsd:element ref="bpmndi:BPMNDiagram" minOccurs="0" maxOccurs="unbounded"/>
    <xsd:element ref="relationship" minOccurs="0" maxOccurs="unbounded"/>
  </xsd:sequence>
  <xsd:attribute name="id" type="xsd:ID" use="optional"/>
  <xsd:attribute name="targetNamespace" type="xsd:anyURI" use="required"/>
  <xsd:attribute name="expressionLanguage" type="xsd:anyURI" use="optional" default="http://www.w3.org/1999/XPath"/>
  <xsd:attribute name="typeLanguage" type="xsd:anyURI" use="optional" default="http://www.w3.org/2001/XMLSchema"/>
  <xsd:anyAttribute name="exporter" type="xsd:ID"/>
  <xsd:anyAttribute name="exporterVersion" type="xsd:ID"/>
  <xsd:anyAttribute namespace="##other" processContents="lax"/>
</xsd:complexType>
```
Table 8.4 – Import XML schema

```xml
<xsd:element name="import" type="tImport"/>
<xsd:complexType name="tImport">
    <xsd:attribute name="namespace" type="xsd:anyURI" use="required"/>
    <xsd:attribute name="location" type="xsd:string" use="required"/>
    <xsd:attribute name="importType" type="xsd:anyURI" use="required"/>
</xsd:complexType>
```

8.2 Foundation

The Foundation package contains classes which are shared amongst other packages in the Core (see Figure 8.5) of a abstract syntax model.

![Figure 8.5 - Classes in the Foundation package](image)

Business Process Model and Notation, v2.0
8.2.1 Base Element

BaseElement is the abstract super class for most BPMN elements. It provides the attributes id and documentation, which other elements will inherit.

Table 8.5 presents the attributes and model associations for the BaseElement.

Table 8.5 – BaseElement attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>id: string</td>
<td>This attribute is used to uniquely identify BPMN elements. The id is REQUIRED if this element is referenced or intended to be referenced by something else. If the element is not currently referenced and is never intended to be referenced, the id MAY be omitted.</td>
</tr>
<tr>
<td>documentation: Documentation [0..*]</td>
<td>This attribute is used to annotate the BPMN element, such as descriptions and other documentation.</td>
</tr>
<tr>
<td>extensionDefinitions: ExtensionDefinition [0..*]</td>
<td>This attribute is used to attach additional attributes and associations to any BaseElement. This association is not applicable when the XML schema interchange is used, since the XSD mechanisms for supporting anyAttribute and any element already satisfy this requirement. See page 57 for additional information on extensibility.</td>
</tr>
<tr>
<td>extensionValues: ExtensionAttributeValue [0..*]</td>
<td>This attribute is used to provide values for extended attributes and model associations. This association is not applicable when the XML schema interchange is used, since the XSD mechanisms for supporting anyAttribute and any element already satisfy this requirement. See page 57 for additional information on extensibility.</td>
</tr>
</tbody>
</table>

8.2.2 Documentation

All BPMN elements that inherit from the BaseElement will have the capability, through the Documentation element, to have one (1) or more text descriptions of that element.

The Documentation element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.6 presents the additional attributes of the Documentation element:

Table 8.6 – Documentation attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>text: string</td>
<td>This attribute is used to capture the text descriptions of a BPMN element.</td>
</tr>
<tr>
<td>textFormat: string</td>
<td>This attribute identifies the format of the text. It MUST follow the mime-type format. The default is &quot;text/plain.&quot;</td>
</tr>
</tbody>
</table>

In the BPMN schema, the tDocumentation complexType does not contain a text attribute or element. Instead, the documentation text is expected to appear in the body of the documentation element. For example:
8.2.3 Extensibility

The BPMN metamodel is aimed to be extensible. This allows BPMN adopters to extend the specified metamodel in a way that allows them to be still BPMN-compliant.

It provides a set of extension elements, which allows BPMN adopters to attach additional attributes and elements to standard and existing BPMN elements.

This approach results in more interchangeable models, because the standard elements are still intact and can still be understood by other BPMN adopters. It’s only the additional attributes and elements that MAY be lost during interchange.

Figure 8.6 - Extension class diagram

A BPMN Extension basically consists of four different elements:

- Extension
- ExtensionDefinition
• ExtensionAttributeDefinition
• ExtensionAttributeValue

The core elements of an Extension are the ExtensionDefinition and ExtensionAttributeDefinition. The latter defines a list of attributes which can be attached to any BPMN element. The attribute list defines the name and type of the new attribute. This allows BPMN adopters to integrate any meta model into the BPMN meta model and reuse already existing model elements.

The ExtensionDefinition itself can be created independent of any BPMN element or any BPMN definition.

In order to use an ExtensionDefinition within a BPMN model definition (Definitions element), the ExtensionDefinition MUST be associated with an Extension element which binds the ExtensionDefinition to a specific BPMN model definition. The Extension element itself is contained within the BPMN element Definitions and therefore available to be associated with any BPMN element making use of the ExtensionDefinition.

Every BPMN element which subclasses the BPMN BaseElement can be extended by additional attributes. This works by associating a BPMN element with an ExtensionDefinition which was defined at the BPMN model definitions level (element Definitions).

Additionally, every “extended” BPMN element contains the actual extension attribute value. The attribute value, defined by the element ExtensionAttributeValue contains the value of type Element. It also has an association to the corresponding attribute definition.

**Extension**

The Extension element binds/imports an ExtensionDefinition and its attributes to a BPMN model definition.

Table 8.7 presents the attributes and model associations for the Extension element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>mustUnderstand: boolean [0..1] = False</td>
<td>This flag defines if the semantics defined by the extension definition and its attribute definition MUST be understood by the BPMN adopter in order to process the BPMN model correctly. Defaults to False.</td>
</tr>
<tr>
<td>definition: ExtensionDefinition</td>
<td>Defines the content of the extension. Note that in the XML schema, this definition is provided by an external XML schema file and is simply referenced by QName.</td>
</tr>
</tbody>
</table>

**ExtensionDefinition**

The ExtensionDefinition class defines and groups additional attributes. This type is not applicable when the XML schema interchange is used, since XSD Complex Types already satisfy this requirement.

Table 8.8 presents the attributes and model associations for the ExtensionDefinition element:
ExtensionAttributeDefinition

The ExtensionAttributeDefinition defines new attributes. This type is not applicable when the XML schema interchange is used; since the XSD mechanisms for supporting “AnyAttribute” and “Any” type already satisfy this requirement.

Table 8.9 presents the attributes for the ExtensionAttributeDefinition element:

Table 8.9 - ExtensionAttributeDefinition attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The name of the extension attribute.</td>
</tr>
<tr>
<td>type: string</td>
<td>The type that is associated with the attribute.</td>
</tr>
<tr>
<td>isReference: boolean [0..1] = False</td>
<td>Indicates if the attribute value will be referenced or contained.</td>
</tr>
</tbody>
</table>

ExtensionAttributeValue

The ExtensionAttributeValue contains the attribute value. This type is not applicable when the XML schema interchange is used; since the XSD mechanisms for supporting “AnyAttribute” and “Any” type already satisfy this requirement.

Table 8.10 presents the model associations for the ExtensionAttributeValue element:

Table 8.10 – ExtensionAttributeValue model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>value: [Element [0..1]]</td>
<td>The contained attribute value, used when the associated ExtensionAttributeDefinition.isReference is false. The type of this Element MUST conform to the type specified in the associated ExtensionAttributeDefinition.</td>
</tr>
<tr>
<td>valueRef: [Element [0..1]]</td>
<td>The referenced attribute value, used when the associated ExtensionAttributeDefinition.isReference is true. The type of this Element MUST conform to the type specified in the associated ExtensionAttributeDefinition.</td>
</tr>
<tr>
<td>extensionAttributeDefinition:</td>
<td>Defines the extension attribute for which this value is being provided.</td>
</tr>
<tr>
<td>ExtensionAttributeDefinition</td>
<td></td>
</tr>
</tbody>
</table>
Extensibility XML Schemas

Table 8.11 – Extension XML schema

```xml
<xsd:element name="extension" type="tExtension"/>
<xsd:complexType name="tExtension">
  <xsd:sequence>
    <xsd:element ref="documentation" minOccurs="0" maxOccurs="unbounded"/>
  </xsd:sequence>
  <xsd:attribute name="definition" type="xsd:QName"/>
  <xsd:attribute name="mustUnderstand" type="xsd:boolean" use="optional"/>
</xsd:complexType>
```

XML Example

This example shows a Task, defined the BPMN Core, being extended with Inputs and Outputs defined outside of the Core.

Table 8.12 – Example Core XML schema

```xml
<xsd:schema ...

  ...
  <xsd:element name="task" type="tTask"/>
  <xsd:complexType name="tTask">
    <xsd:complexContent>
      <xsd:extension base="tActivity"/>
    </xsd:complexContent>
  </xsd:complexType>

  ...
</xsd:schema>
```
8.2.4 External Relationships

It is the intention of this specification to cover the basic elements necessary for the construction of semantically rich and syntactically valid Process models to be used in the description of Processes, Choreographies and business operations in multiple levels of abstraction. As the specification indicates, extension capabilities enable the enrichment of the information described in BPMN and supporting models to be augmented to fulfill particularities of a given usage model. These extensions intention is to extend the semantics of a given BPMN Artifact to provide specialization of intent or meaning.

Table 8.13 – Example Extension XML schema

```xml
<xsd:schema ...>
    ...
    <xsd:group name="dataRequirements">
        <xsd:sequence>
            <xsd:element ref="dataInput" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="dataOutput" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="inputSet" minOccurs="0" maxOccurs="unbounded"/>
            <xsd:element ref="outputSet" minOccurs="0" maxOccurs="unbounded"/>
        </xsd:sequence>
    </xsd:group>
    ...
</xsd:schema>
```

Table 8.14 – Sample XML instance

```xml
<bpmn:definitions id="ID_1" ...>
    ...
    <bpmn:extension mustUnderstand="true" definition="bpmn:dataRequirements"/>
    ...
    <bpmn:task name="Retrieve Customer Record" id="ID_2">
        <bpmn:dataInput name="Order Input" id="ID_3">
            <bpmn:typeDefinition typeRef="bo:Order" id="ID_4"/>
        </bpmn:dataInput>
        <bpmn:dataOutput name="Customer Record Output" id="ID_5">
            <bpmn:typeDefinition typeRef="bo:CustomerRecord" id="ID_6"/>
        </bpmn:dataOutput>
        <bpmn:inputSet name="Inputs" id="ID_7" dataInputRefs="ID_3"/>
        <bpmn:outputSet name="Outputs" id="ID_8" dataOutputRefs="ID_5"/>
    </bpmn:task>
    ...
</bpmn:definitions>
```
Process models do not exist in isolation and generally participate in larger, more complex business and system development Processes. The intention of the following specification element is to enable BPMN Artifacts to be integrated in these development Processes via the specification of a non-intrusive identity/relationship model between BPMN Artifacts and elements expressed in any other addressable domain model.

The ‘identity/relationship’ model it is reduced to the creation of families of typed relationships that enable BPMN and non-BPMN Artifacts to be related in non intrusive manner. By simply defining ‘relationship types’ that can be associated with elements in the BPMN Artifacts and arbitrary elements in a given addressable domain model, it enables the extension and integration of BPMN models into larger system/development Processes.

It is that these extensions will enable, for example, the linkage of ‘derivation’ or ‘definition’ relationships between UML artifacts and BPMN Artifacts in novel ways. So, a UML use case could be related to a Process element in the BPMN specification without affecting the nature of the Artifacts themselves, but enabling different integration models that traverse specialized relationships.

Simply, the model enables the external specification of augmentation relationships between BPMN Artifacts and arbitrary relationship classification models, these external models, via traversing relationships declared in the external definition allow for linkages between BPMN elements and other structured or non-structured metadata definitions.

The UML model for this specification follow a simple extensible pattern as shown below; where named relationships can be established by referencing objects that exist in their given namespaces.

Figure 8.7 - External Relationship Metamodel

The Relationship element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.15 presents the additional attributes for the Relationship element:
In this manner, you can, for example, create relationships between different artifacts that enable external annotations used for (for example) traceability, derivation, arbitrary classifications, etc.

An example where the ‘reengineer’ relationship is shown between elements in a Visio™ artifact and a BPMN Artifact.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>type: string</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>direction: RelationshipDirection</td>
<td>This attribute specifies the direction of the relationship.</td>
</tr>
<tr>
<td>sources: [Element [1..*]]</td>
<td>This association defines artifacts that are augmented by the relationship.</td>
</tr>
<tr>
<td>targets: [Element[1..*]]</td>
<td>This association defines artifacts used to extend the semantics of the source element(s).</td>
</tr>
</tbody>
</table>

Table 8.16 – Reengineer XML schema

```xml
<?xml version="1.0" encoding="UTF-8"?>

<import importType="http://office.microsoft.com/visio" location="OrderConfirmationProcess.vsd" namespace="http://www.example.org/Processes/Old"/>

<relationship type="reengineered" id="a234" direction="both">
  <documentation>An as-is and to-be relationship. The as-is model is expressed as a Visio diagram. The re-engineered process has been split in two and is captured in BPMN 2.0 format.</documentation>
  <source ref="src:OrderConfirmation"/>
  <target ref="tgt:OrderConfirmation_PartI"/>
  <target ref="tgt:OrderConfirmation_PartII"/>
</relationship>
</definitions>
```
8.2.5 Root Element

RootElement is the abstract super class for all BPMN elements that are contained within Definitions. When contained within Definitions, these elements have their own defined life-cycle and are not deleted with the deletion of other elements. Examples of concrete RootElements include Collaboration, Process, and Choreography. Depending on their use, RootElements can be referenced by multiple other elements (i.e., they can be reused). Some RootElements MAY be contained within other elements instead of Definitions. This is done to avoid the maintenance overhead of an independent life-cycle. For example, an EventDefinition would be contained in a Process since it is used only there. In this case the EventDefinition would be dependent on the tool life-cycle of the Process.

The RootElement element inherits the attributes and model associations of BaseElement (see Table 8.5), but does not have any further attributes or model associations.

8.2.6 Foundation Package XML Schemas

Table 8.17 – BaseElement XML schema

```xml
<xsd:element name="baseElement" type="tBaseElement"/>
<xsd:complexType name="tBaseElement" abstract="true">
  <xsd:sequence>
    <xsd:element ref="documentation" minOccurs="0" maxOccurs="unbounded"/>
    <xsd:element ref="extensionElements" minOccurs="0" maxOccurs="1"/>

```
8.3 Common Elements

The following sections define BPMN elements that MAY be used in more than one type of diagram (e.g., Process, Collaboration, and Choreography).

8.3.1 Artifacts

BPMN provides modelers with the capability of showing additional information about a Process that is not directly related to the Sequence Flows or Message Flows of the Process.

At this point, BPMN provides three (3) standard Artifacts: Associations, Groups, and Text Annotations. Additional Artifacts MAY be added to the BPMN specification in later versions. A modeler or modeling tool MAY extend a BPMN diagram and add new types of Artifacts to a Diagram. Any new Artifact MUST follow the Sequence Flow and Message Flow connection rules (listed below). Associations can be used to link Artifacts to Flow Objects (see page 67).

Figure 8.8 shows the Artifacts class diagram. When an Artifact is defined it is contained within a Collaboration or a FlowElementsContainer (a Process or Choreography).
Common Artifact Definitions
The following sections provide definitions that are common to all Artifacts.

Artifact Sequence Flow Connections
See “Sequence Flow Rules,” on page 42 for the entire set of objects and how they MAY be source or targets of a Sequence Flow.

- An Artifact MUST NOT be a target for a Sequence Flow.
- An Artifact MUST NOT be a source for a Sequence Flow.

Artifact Message Flow Connections
See “Message Flow Rules,” on page 43 for the entire set of objects and how they MAY be source or targets of a Message Flow.

- An Artifact MUST NOT be a target for a Message Flow.
- An Artifact MUST NOT be a source for a Message Flow.

Association
An Association is used to associate information and Artifacts with Flow Objects. Text and graphical non-Flow Objects can be associated with the Flow Objects and Flow. An Association is also used to show the Activity used for compensation. More information about compensation can be found on page 311.

- An Association is line that MUST be drawn with a dotted single line (see Figure 8.9).
- The use of text, color, size, and lines for an Association MUST follow the rules defined in section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

Figure 8.9 - An Association
If there is a reason to put directionality on the Association then:

- A line arrowhead MAY be added to the Association line (see Figure 8.11).
- The directionality of the Association can be in one (1) direction or in both directions.

Figure 8.11 - A Directional Association

Note that directional Associations were used in BPMN 1.2 to show how Data Objects were inputs or outputs to Activities. In BPMN 2.0, a Data Association connector is used to show inputs and outputs (see page 228). A Data Association uses the same notation as a directed Association (as in Figure 8.11, above).

An Association is used to connect user-defined text (an Annotation) with a Flow Object (see Figure 8.12).

Figure 8.12 - An Association of Text Annotation
The **Association** element inherits the attributes and model associations of **BaseElement** (see Table 8.5). Table 8.20 presents the additional attributes and model associations for an **Association**:

### Table 8.20 – Association attributes and model associations

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>associationDirection</strong></td>
<td><code>associationDirection</code> is an attribute that defines whether or not the Association shows any directionality with an arrowhead. The default is None (no arrowhead). A value of One means that the arrowhead SHALL be at the Target Object. A value of Both means that there SHALL be an arrowhead at both ends of the Association line.</td>
</tr>
<tr>
<td><strong>sourceRef</strong>: BaseElement</td>
<td>The <strong>BaseElement</strong> that the <strong>Association</strong> is connecting from.</td>
</tr>
<tr>
<td><strong>targetRef</strong>: BaseElement</td>
<td>The <strong>BaseElement</strong> that the <strong>Association</strong> is connecting to.</td>
</tr>
</tbody>
</table>

**Group**

The **Group** object is an **Artifact** that provides a visual mechanism to group elements of a diagram informally. The grouping is tied to the **CategoryValue** supporting element. That is, a **Group** is a visual depiction of a single **CategoryValue**. The graphical elements within the **Group** will be assigned the **CategoryValue** of the **Group**. (Note -- **CategoryValues** can be highlighted through other mechanisms, such as color, as defined by a modeler or a modeling tool).

- A **Group** is a rounded corner rectangle that MUST be drawn with a solid dashed line (as seen in Figure 8.13).
- The use of text, color, size, and lines for a **Group** MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

![Figure 8.13 - A Group Artifact](image-url)

As an **Artifact**, a **Group** is not an **Activity** or any **Flow Object**, and, therefore, cannot connect to **Sequence Flows** or **Message Flows**. In addition, **Groups** are not constrained by restrictions of **Pools** and **Lanes**. This means that a **Group** can stretch across the boundaries of a **Pool** to surround **Diagram** elements (see Figure 8.14), often to identify **Activities** that exist within a distributed business-to-business transaction.
Groups are often used to highlight certain sections of a Diagram without adding additional constraints for performance-as a Sub-Process would. The highlighted (grouped) section of the Diagram can be separated for reporting and analysis purposes. Groups do not affect the flow of the Process.

Figure 8.15 shows the Group class diagram.
The **Group** element inherits the attributes and model associations of **BaseElement** (see Table 8.5), through its relationship to **Artifact**. Table 8.21 presents the additional model associations for a **Group**.

**Table 8.21 – Group model associations**

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>categoryValueRef: Category-Value [0..1]</td>
<td>The <code>categoryValueRef</code> attribute specifies the <code>CategoryValue</code> that the <strong>Group</strong> represents (Further details about the definition of a <strong>Category</strong> and <strong>CategoryValue</strong> can be found on page 71). The name of the <strong>Category</strong> and the value of the <strong>CategoryValue</strong> separated by delineator &quot;.&quot; provides the label for the <strong>Group</strong>. The graphical elements within the boundaries of the <strong>Group</strong> will be assigned the <strong>CategoryValue</strong>.</td>
</tr>
</tbody>
</table>

**Category**

**Categories**, which have user-defined semantics, can be used for documentation or analysis purposes. For example, **FlowElements** can be categorized as being customer oriented vs. support oriented. Furthermore, the cost and time of **Activities** per **Category** can be calculated.

**Groups** are one way in which **Categories** of objects can be visually displayed on the diagram. That is, a **Group** is a visual depiction of a single **CategoryValue**. The graphical elements within the **Group** will be assigned the **CategoryValue** of the **Group**. The value of the **CategoryValue**, optionally prepended by the **Category** name and delineator ".", appears on the diagram as the **Group** label. (Note -- **Categories** can be highlighted through other mechanisms, such as color, as defined by a modeler or a modeling tool). A single **Category** can be used for multiple **Groups** in a diagram.

The **Category** element inherits the attributes and model associations of **BaseElement** (see Table 8.5) through its relationship to **RootElement**. Table 8.22 displays the additional model associations of the **Category** element.

**Table 8.22 – Category model associations**

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>categoryValue: CategoryValue [0..*]</td>
<td>The <code>categoryValue</code> attribute specifies one or more values of the <strong>Category</strong>. For example, the <strong>Category</strong> is &quot;Region&quot; then this <strong>Category</strong> could specify values like &quot;North,&quot; &quot;South,&quot; &quot;West,&quot; and &quot;East.&quot;</td>
</tr>
</tbody>
</table>

The **CategoryValue** element inherits the attributes and model associations of **BaseElement** (see Table 8.5). Table 8.23 displays the attributes and model associations of the **CategoryValue** element.
Text Annotation

Text Annotations are a mechanism for a modeler to provide additional information for the reader of a BPMN Diagram.

- A Text Annotation is an open rectangle that MUST be drawn with a solid single line (as seen in Figure 8.16).
- The use of text, color, size, and lines for a Text Annotation MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

The Text Annotation object can be connected to a specific object on the Diagram with an Association, but do not affect the flow of the Process. Text associated with the Annotation can be placed within the bounds of the open rectangle.

Figure 8.16 - A Text Annotation

The Text Annotation element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.24 presents the additional attributes for a Text Annotation:

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>text: string</td>
<td>Text is an attribute that is text that the modeler wishes to communicate to the reader of the Diagram.</td>
</tr>
<tr>
<td>textFormat: string</td>
<td>This attribute identifies the format of the text. It MUST follow the mime-type format. The default is &quot;text/plain.&quot;</td>
</tr>
</tbody>
</table>
**XML Schema for Artifacts**

Table 8.25 – Artifact XML schema

```
8.3.2 Correlation

Business Processes typically can run for days or even months, requiring asynchronous communication via Message. Also, many instances of a particular Process will typically run in parallel, e.g., many instances of an order process, each representing a particular order. Correlation is used to associate a particular Message to an ongoing Conversation between two particular Process instances. BPMN allows using existing Message data for correlation purposes, e.g., for the order process, a particular instance can be identified by means of its orderID and/or customerID, rather than requiring the introduction of technical correlation data.

The concept of Correlation facilitates the association of a Message to a Send Task or Receive Task\(^1\) often in the context of a Conversation, which is also known as instance routing. It is a particular useful concept where there is no infrastructure support for instance routing. Note that this association can be viewed at multiple levels, namely the Collaboration (Conversation), Choreography, and Process level. However, the actual correlation happens during runtime (e.g., at the Process level). Correlations describe a set of predicates on a Message (generally on the application payload) that need to be satisfied in order for that Message to be associated to a distinct Send Task or Receive Task. By the same token, each Send Task and each Receive Task participates in one or many Conversations. Furthermore, it identifies the Message it sends or receives and thereby establishes the relationship to one (or many) CorrelationKeys.

There are two, non-exclusive correlation mechanisms in place:

- In plain, key-based correlation, Messages that are exchanged within a Conversation are logically correlated by means of one or more common CorrelationKeys. That is, any Message that is sent or received within this Conversation needs to carry the value of at least one of those CorrelationKey instances within its payload. A CorrelationKey basically defines a (composite) key. The first Message that is initially sent or received initializes one or more CorrelationKey instances associated with the Conversation, i.e., assigns values to its CorrelationProperty instances which are the fields (partial keys) of the CorrelationKey. A CorrelationKey is only considered valid for use, if the Message has resulted in all CorrelationProperty fields within the key being populated with a value. If a follow-up Message derives a CorrelationKey instance, where that CorrelationKey had previously been initialized within the Conversation, then the CorrelationKey value in the Message and Conversation MUST match. If the follow-up Message derives a CorrelationKey instance associated with the Conversation, that had not previously been initialized, then the CorrelationKey value will become associated with the Conversation. As a Conversation can comprise different Messages that can be differently structured, each CorrelationProperty comes with as many extraction rules (CorrelationPropertyRetrievalExpression) for the respective partial key as there are different Messages.

In context-based correlation, the Process context (i.e., its Data Objects and Properties) can dynamically influence the matching criterion. That is, a CorrelationKey can be complemented by a Process-specific CorrelationSubscription. A CorrelationSubscription aggregates as many CorrelationPropertyBindings as there are CorrelationProperties in the CorrelationKey. A CorrelationPropertyBinding relates to a specific CorrelationProperty and also links to a FormalExpression which denotes a dynamic extraction rule atop the Process context. At runtime, the CorrelationKey instance for a particular Conversation is populated (and dynamically updated) from the Process context using these FormalExpressions. In that sense, changes in the Process context can alter the correlation condition. Correlation can be applied to Message Flows in Collaboration and Choreography, as described in Chapters 9, Collaboration and 11, Choreography. The keys applying to a Message Flow are the keys of containers or

---

1. All references to Send or Receive Tasks in this section also include message catch or throw Events -- they behave identically with respect to correlation.
groupings of the *Message Flow*, such as *Collaborations*, *Choreographies*, and *Conversation Nodes*, and *Choreography Activities*. This might result in multiple *CorrelationKeys* applying to the same *Message Flow*, perhaps due to multiple layers of containment. In particular, calls of *Collaborations* and *Choreographies* are special kinds of *Conversation Nodes* and *Choreography Activities*, respectively, and are considered a kind of containment for the purposes of *correlation*. The *CorrelationKeys* specified in the caller apply to *Message Flow* in a called *Collaboration* or *Choreography*.

Figure 8.17 - The Correlation Class Diagram

*CorrelationKey*

A *CorrelationKey* represents a composite key out of one (1) or many *CorrelationProperties* which essentially specify extraction *Expressions* atop *Messages*. As a result, each *CorrelationProperty* acts as a partial key for the *correlation*. For each *Message* that is exchanged as part of a particular *Conversation*, the
CorrelationProperties need to provide a CorrelationPropertyRetrievalExpression which references a FormalExpression to the Message payload. That is, for each Message (that is used in a Conversation) there is an Expression which extracts portions of the respective Message’s payload.

The CorrelationKey element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.31 displays the additional model associations of the CorrelationKey element.

### Key-based Correlation

Key-based correlation is a simple and efficient form of correlation, where one or more keys are used to identify a Conversation. Any incoming Message can be matched against the CorrelationKey by extracting the CorrelationProperties from the Message according to the corresponding CorrelationPropertyRetrievalExpression and comparing the resulting composite key with the CorrelationKey instance for this Conversation. The idea is to use a joint Conversation “token” which is used (passed to and received from) and outgoing and incoming Message. Messages are associated to a particular Conversation if the composite key extracted from their payload matches the CorrelationKey initialized for this Conversation.

At runtime the first Send Task or Receive Task in a Conversation MUST populate atleast one of the CorrelationKey instances by extracting the values of the CorrelationProperties according to the CorrelationPropertyRetrievalExpression from the initially sent or received Message. Later in the Conversation, the populated CorrelationKey instances are used for the described matching procedure where from incoming Messages a composite key is extracted and used to identify the associated Conversation. Where these non-initiating Messages derive values for CorrelationKeys, associated with the Conversation but not yet populated, then the derived value will be associated with the Conversation instance.

The CorrelationProperty element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to RootElement. Table 8.32 displays the additional model associations of the CorrelationProperty element.
Table 8.32 – CorrelationProperty model associations

<table>
<thead>

<tbody>
<tr>
<td>messagePath: FormalExpression</td>
<td>The FormalExpression that defines how to extract a CorrelationProperty from the Message payload</td>
</tr>
<tr>
<td>messageRef: Message</td>
<td>The specific Message the FormalExpression extracts the CorrelationProperty from.</td>
</tr>
</tbody>
</table>

Context-based Correlation

Context-based correlation is a more expressive form of correlation on top of key-based correlation. In addition to implicitly populating the CorrelationKey instance from the first sent or received Message, another mechanism relates the CorrelationKey to the Process context. That is, a Process MAY provide a CorrelationSubscription which acts as the Process-specific counterpart to a specific CorrelationKey. In this way, a Conversation MAY additionally refer to explicitly updateable Process context data to determine whether or not a Message needs to be received. At runtime, the CorrelationKey instance holds a composite key that is dynamically calculated from the Process context and automatically updated whenever the underlying Data Objects or Properties change.

CorrelationPropertyBindings represent the partial keys of a CorrelationSubscription where each relates to a specific CorrelationProperty in the associated CorrelationKey. A FormalExpression defines how that CorrelationProperty instance is populated and updated at runtime from the Process context (i.e., its Data Objects and Properties).

The CorrelationSubscription element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.34 displays the additional model associations of the CorrelationSubscription element.
The `CorrelationPropertyBinding` element inherits the attributes and model associations of `BaseElement` (see Table 8.5). Table 8.35 displays the additional model associations of the `CorrelationPropertyBinding` element.

At runtime, the correlation mechanism works as follows: When a `Process` instance is created the `CorrelationKey` instances of all `Conversations` are initialized with some initial values that specify to correlate any incoming `Message` for these `Conversations`. A `SubscriptionProperty` is updated whenever any of the `Data Objects` or `Properties` changes that are referenced from the respective `FormalExpression`. As a result, incoming `Messages` are matched against the now populated `CorrelationKey` instance. Later in the `Process` run, the `SubscriptionProperties` can, again, change and implicitly change the correlation criterion. Alternatively, the established mechanism of having the first `Send Task` or `Receive Task` populate the `CorrelationKey` applies.

        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```
8.3.3 Error

An Error represents the content of an Error Event or the Fault of a failed Operation. An ItemDefinition is used to specify the structure of the Error. An Error is generated when there is a critical problem in the processing of an Activity or when the execution of an Operation failed.

![Error class diagram]

The Error element inherits the attributes and model associations of BaseElement (see Table 8.5), through its relationship to RootElement. Table 8.41 presents the additional attributes and model associations of the Error element:
### 8.3.4 Escalation

An Escalation identifies a business situation that a Process might need to react to. An ItemDefinition is used to specify the structure of the Escalation.

#### Table 8.41 – Error attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>structureRef : ItemDefinition [0..1]</td>
<td>An ItemDefinition is used to define the “payload” of the Error.</td>
</tr>
<tr>
<td>name : string</td>
<td>The descriptive name of the Error.</td>
</tr>
</tbody>
</table>
| errorCode: string | For an End Event:  
If the result is an Error, then the errorCode MUST be supplied (if the processType attribute of the Process is set to executable) This “throws” the Error.  
For an Intermediate Event within normal flow:  
If the trigger is an Error, then the errorCode MUST be entered (if the processType attribute of the Process is set to executable). This “throws” the Error.  
For an Intermediate Event attached to the boundary of an Activity:  
If the trigger is an Error, then the errorCode MAY be entered. This Event “catches” the Error. If there is no errorCode, then any error SHALL trigger the Event. If there is an errorCode, then only an Error that matches the errorCode SHALL trigger the Event. |

#### Figure 8.19 - Escalation class diagram
The Escalation element inherits the attributes and model associations of BaseElement (see Table 8.5), through its relationship to RootElement. Table 8.41 presents the additional model associations of the Error element:

Table 8.42 – Escalation attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>structureRef : ItemDefinition [0..1]</td>
<td>An ItemDefinition is used to define the “payload” of the Escalation.</td>
</tr>
<tr>
<td>name : string</td>
<td>The descriptive name of the Escalation.</td>
</tr>
</tbody>
</table>
| escalationCode : string | For an End Event:
  If the Result is an Escalation, then the escalationCode MUST be supplied (if the processType attribute of the Process is set to executable). This “throws” the Escalation.

For an Intermediate Event within normal flow:
  If the trigger is an Escalation, then the escalationCode MUST be entered (if the processType attribute of the Process is set to executable). This “throws” the Escalation.

For an Intermediate Event attached to the boundary of an Activity:
  If the trigger is an Escalation, then the escalationCode MAY be entered. This Event “catches” the Escalation. If there is no escalationCode, then any Escalation SHALL trigger the Event. If there is an escalationCode, then only an Escalation that matches the escalationCode SHALL trigger the Event. |

8.3.5 Events

An Event is something that “happens” during the course of a Process. These Events affect the flow of the Process and usually have a cause or an impact. The term “event” is general enough to cover many things in a Process. The start of an Activity, the end of an Activity, the change of state of a document, a Message that arrives, etc., all could be considered Events. However, BPMN has restricted the use of Events to include only those types of Events that will affect the sequence or timing of Activities of a Process.
The **Event** element inherits the attributes and model associations of **FlowElement** (see Table 8.44), but adds no additional attributes or model associations:

The details for the types of **Events** (Start, Intermediate, and End) are defined in the Section “Event Definitions” on page 268.

### 8.3.6 Expressions

The **Expression** class is used to specify an Expression using natural-language text. These Expressions are not executable. The natural language text is captured using the documentation attribute, inherited from **BaseElement**.

Expression inherits the attributes and model associations of **BaseElement** (see Table 8.5), but adds no additional attributes or model associations.
Expressions are used in many places within BPMN to extract information from the different elements, normally data elements. The most common usage is when modeling decisions, where conditional Expressions are used to direct the flow along specific paths based on some criteria.

BPMN supports underspecified Expressions, where the logic is captured as natural-language descriptive text. It also supports formal Expressions, where the logic is captured in an executable form using a specified Expression language.

**Figure 8.21 - Expression class diagram**

**Expression**

The Expression class is used to specify an Expression using natural-language text. These Expressions are not executable and are considered underspecified.

The definition of an Expression can be done in two ways: it can be contained where it is used, or it can be defined at the Process level and then referenced where it is used.

The Expression element inherits the attributes and model associations of BaseElement (see Table 8.5), but does not have any additional attributes or model associations.

**Formal Expression**

The FormalExpression class is used to specify an executable Expression using a specified Expression language. A natural-language description of the Expression can also be specified, in addition to the formal specification.

The default Expression language for all Expressions is specified in the Definitions element, using the expressionLanguage attribute. It can also be overridden on each individual FormalExpression using the same attribute.

The FormalExpression element inherits the attributes and model associations of BaseElement (see Table 8.5), through the Expression element. Table 8.43 presents the additional attributes and model associations of the FormalExpression:
FlowElement is the abstract super class for all elements that can appear in a Process flow, which are FlowNodes (see page 99, which consist of Activities (see page 155), Choreography Activities (see page 331) Gateways (see page 295), and Events (see page 240)), Data Objects (see page 212), Data Associations (see page 228), and Sequence Flows (see page 97).
Figure 8.22 - FlowElement class diagram

The FlowElement element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.44 presents the additional attributes and model associations of the FlowElement element:
8.3.8 Flow Elements Container

**FlowElementsContainer** is an abstract super class for **BPMN** diagrams (or views) and defines the superset of elements that are contained in those diagrams. Basically, a FlowElementsContainer contains FlowElements, which are **Events** (see page 240), **Gateways** (see page 295), **Sequence Flows** (see page 97), **Activities** (see page 155), and **Choreography Activities** (see page 331).

There are four (4) types of FlowElementsContainers (see Figure 8.23): **Process**, **Sub-Process**, **Choreography**, and **Sub-Choreography**.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>categoryValueRef: Category-Value [0..*]</td>
<td>A reference to the Category Values that are associated with this Flow Element.</td>
</tr>
<tr>
<td>auditing: Auditing [0..1]</td>
<td>A hook for specifying audit related properties. Auditing can only be defined for a Process.</td>
</tr>
<tr>
<td>monitoring: Monitoring [0..1]</td>
<td>A hook for specifying monitoring related properties. Monitoring can only be defined for a Process.</td>
</tr>
</tbody>
</table>
Figure 8.23 - FlowElementsContainer class diagram

The FlowElementsContainer element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.45 presents the additional model associations of the FlowElementsContainer element.

Table 8.45 – FlowElementsContainer model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
</table>
| **flowElements**: Flow Element [0..*] | This association specifies the particular flow elements contained in a FlowElementContainer. Flow elements are Events, Gateways, Sequence Flows, Activities, Data Objects, Data Associations, and Choreography Activities. Note that:  
  - Choreography Activities MUST NOT be included as a flowElement for a Process.  
  - Activities, Data Associations, and Data Objects MUST NOT be included as a flowElement for a Choreography. |
| **laneSets**: LaneSet [0..*] | This attribute defines the list of LaneSets used in the FlowElementsContainer. LaneSets are not used for Choreographies or Sub-Choreographies. |
8.3.9 Gateways

Gateways are used to control how the Process flows (how Tokens flow) through Sequence Flows as they converge and diverge within a Process. If the flow does not need to be controlled, then a Gateway is not needed. The term “gateway” implies that there is a gating mechanism that either allows or disallows passage through the Gateway—that is, as tokens arrive at a Gateway, they can be merged together on input and/or split apart on output as the Gateway mechanisms are invoked.

Gateways, like Activities, are capable of consuming or generating additional control tokens, effectively controlling the execution semantics of a given Process. The main difference is that Gateways do not represent ‘work’ being done and they are considered to have zero effect on the operational measures of the Process being executed (cost, time, etc.).

The Gateway controls the flow of both diverging and converging Sequence Flows. That is, a single Gateway could have multiple input and multiple output flows. Modelers and modeling tools might want to enforce a best practice of a Gateway only performing one of these functions. Thus, it would take two sequential Gateways to first converge and then to diverge the Sequence Flows.

Figure 8.24 - Gateway class diagram

The details for the types of Gateways (Exclusive, Inclusive, Parallel, Event-Based, and Complex) is defined on page 295 for Processes and on page 355 for Choreographies.
The **Gateway** class is an abstract type. Its concrete subclasses define the specific semantics of individual **Gateway** types, defining how the **Gateway** behaves in different situations.

The **Gateway** element inherits the attributes and model associations of **FlowElement** (see Table 8.44). Table 8.46 presents the additional attributes of the **Gateway** element.

**Table 8.46 – Gateway attributes**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>gatewayDirection</strong>: GatewayDirection = Unspecified { Unspecified</td>
<td>Converging</td>
</tr>
</tbody>
</table>

- **Unspecified**: There are no constraints. The **Gateway** MAY have any number of **incoming** and **outgoing Sequence Flows**.
- **Converging**: This **Gateway** MAY have multiple **incoming Sequence Flows** but MUST have no more than one (1) **outgoing Sequence Flow**.
- **Diverging**: This **Gateway** MAY have multiple **outgoing Sequence Flows** but MUST have no more than one (1) **incoming Sequence Flow**.
- **Mixed**: This **Gateway** contains multiple **outgoing** and multiple **incoming Sequence Flows**.

### 8.3.10 Item Definition

**BPMN** elements, such as **DataObjects** and **Messages**, represent items that are manipulated, transferred, transformed or stored during **Process** flows. These items can be either physical items, such as the mechanical part of a vehicle, or information items such the catalog of the mechanical parts of a vehicle.

An important characteristics of items in **Process** is their structure. **BPMN** does not require a particular format for this data structure, but it does designate XML Schema as its default. The **structure** attribute references the actual data structure.

The default format of the data structure for all elements can be specified in the **Definitions** element using the **typeLanguage** attribute. For example, a **typeLanguage** value of [http://www.w3.org/2001/XMLSchema](http://www.w3.org/2001/XMLSchema) indicates that the data structures using by elements within that Definitions are in the form of XML Schema types. If unspecified, the default is XML schema. An Import is used to further identify the location of the data structure (if applicable). For example, in the case of data structures contributed by an XML schema, an Import would be used to specify the file location of that schema.

Structure definitions are always defined as separate entities, so they cannot be inlined in one of their usages. You will see that in every mention of structure definition there is a “reference” to the element. This is why this class inherits from **RootElement**.

An **ItemDefinition** element can specify an import reference where the proper definition of the structure is defined.
In cases where the data structure represents a collection, the multiplicity can be projected into the attribute `isCollection`. If this attribute is set to “true,” but the actual type is not a collection type, the model is considered as invalid. BPMN compliant tools might support an automatic check for these inconsistencies and report this as an error. The default value for this element is “false.”

The `itemKind` attribute specifies the nature of an item which can be a physical or an information item.

Figure 8.25 shows the `ItemDefinition` class diagram. When an `ItemDefinition` is defined it is contained in `Definitions`.

![ItemDefinition class diagram](image)

**Figure 8.25 - ItemDefinition class diagram**

The `ItemDefinition` element inherits the attributes and model associations `BaseElement` (see Table 8.5) through its relationship to `RootElement`. Table 8.47 presents the additional attributes and model associations for the `ItemDefinition` element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemKind: ItemKind = Information { Information</td>
<td>Physical }</td>
</tr>
<tr>
<td>structureRef: [Element [0..1]]</td>
<td>The concrete data structure to be used.</td>
</tr>
<tr>
<td>import: Import [0..1]</td>
<td>Identifies the location of the data structure and its format. If the <code>importType</code> attribute is left unspecified, the <code>typeLanguage</code> specified in the <code>Definitions</code> that contains this <code>ItemDefinition</code> is assumed.</td>
</tr>
<tr>
<td>isCollection: boolean = False</td>
<td>Setting this flag to <code>true</code> indicates that the actual data type is a collection.</td>
</tr>
</tbody>
</table>
8.3.11 Message

A Message represents the content of a communication between two Participants. In BPMN 2.0, a Message is a graphical decorator (it was a supporting element in BPMN 1.2). An ItemDefinition is used to specify the Message structure.

When displayed in a diagram:

- In a Message is a rectangle with converging diagonal lines in the upper half of the rectangle to give the appearance of an envelope (see Figure 8.26). It MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Message MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

Figure 8.26 - A Message

In addition, when used in a Choreography Diagram more than one Message MAY be used for a single Choreography Task. In this case, it is important to know the first (initiating) Message of the interaction. For return (non-initiating) Messages the symbol of the Message is shaded with a light fill (see Figure 8.27).

Figure 8.27 - A non-initiating Message

- Any Message sent by the non-initiating Participant or Sub-Choreography MUST be shaded with a light fill..

In a Collaboration, the communication itself is represented by a Message Flow (see the Section “Message Flow” below for more details). The Message can be optionally depicted as a graphical decorator on a Message Flow in a Collaboration (see Figure 8.28 and Figure 8.28).
In a **Choreography**, the communication is represented by a **Choreography Task** (see page 333). The **Message** can be depicted as a decorator with a **Choreography Task** in a **Choreography** (see Figure 8.29).

Figure 8.29 - Messages shown Associated with a Choreography Task

Figure 8.30 displays the class diagram showing the attributes and model associations for the **Message** element.
The Message element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to RootElement. Table 8.48 presents the additional attributes and model associations for the Message element:

![Diagram of Message class diagram]

### Table 8.48 – Message attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the Message.</td>
</tr>
<tr>
<td>itemRef: ItemDefinition [0..1]</td>
<td>An ItemDefinition is used to define the “payload” of the Message.</td>
</tr>
</tbody>
</table>

### 8.3.12 Resources

The Resource class is used to specify resources that can be referenced by Activities. These Resources can be Human Resources as well as any other resource assigned to Activities during Process execution time.

The definition of a Resource is “abstract,” because it only defines the Resource, without detailing how e.g., actual user IDs are associated at runtime. Multiple Activities can utilize the same Resource.
Every Resource can define a set of ResourceParameters. These parameters can be used at runtime to define query e.g., into an Organizational Directory. Every Activity referencing a parameterized Resource can bind values available in the scope of the Activity to these parameters.

![Resource class diagram](image)

**Figure 8.31 - Resource class diagram**

The Resource element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to RootElement. Table 8.51 presents the additional model associations for the Resource element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>This attribute specifies the name of the Resource.</td>
</tr>
<tr>
<td>resourceParameters: ResourceParameter [0..*]</td>
<td>This model association specifies the definition of the parameters needed at runtime to resolve the Resource.</td>
</tr>
</tbody>
</table>

As mentioned before, the Resource can define a set of parameters to define a query to resolve the actual resources (e.g., user ids).

The ResourceParameter element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to RootElement. Table 8.51 presents the additional model associations for the ResourceParameter element:
8.3.13 Sequence Flow

A **Sequence Flow** is used to show the order of **Flow Elements** in a **Process** or a **Choreography**. Each **Sequence Flow** has only one **source** and only one **target**. The **source** and **target** MUST be from the set of the following **Flow Elements**: **Events** (**Start**, **Intermediate**, and **End**), **Activities** (**Task** and **Sub-Process**; for **Processes**), **Choreography Activities** (**Choreography Task** and **Sub-Choreography**; for **Choreographies**), and **Gateways**.

- A **Sequence Flow** is line with a solid arrowhead that MUST be drawn with a solid single line (as seen in Figure 8.32).
- The use of text, color, size, and lines for a **Sequence Flow** MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

---

**Figure 8.32 - A Sequence Flow**

A **Sequence Flow** can optionally define a condition **Expression**, indicating that the **token** will be passed down the **Sequence Flow** only if the **Expression** evaluates to **true**. This **Expression** is typically used when the source of the **Sequence Flow** is a **Gateway** or an **Activity**.

- A **conditional outgoing Sequence Flow** from an **Activity** MUST be drawn with a mini-diamond marker at the beginning of the connector (as seen in Figure 8.33).
- If a **conditional Sequence Flow** is used from a source **Activity**, then there MUST be at least one other **outgoing Sequence Flow** from that **Activity**.
- **Conditional outgoing Sequence Flows** from a **Gateway** MUST NOT be drawn with a mini-diamond marker at the beginning of the connector.
- A source **Gateway** MUST NOT be of type **Parallel** or **Event**.

---

**Figure 8.33 - A Conditional Sequence Flow**
A **Sequence Flow** that has an **Exclusive**, **Inclusive**, or **Complex Gateway** or an **Activity** as its source can also be defined with as **default**. Such a **Sequence Flow** will have a marker to show that it is a **default** flow. The **default Sequence Flow** is taken (a token is passed) only if all the other outgoing **Sequence Flows** from the **Activity** or **Gateway** are not valid (i.e., their condition **Expressions are false**)

- A **default outgoing Sequence Flow** MUST be drawn with a slash marker at the beginning of the connector (as seen in Figure 8.34).

![Figure 8.34 - A Default Sequence Flow](image)

The **Sequence Flow** element inherits the attributes and model associations of **FlowElement** (see Table 8.44). Table 8.51 presents the additional attributes and model associations of the **Sequence Flow** element:
Table 8.51 – SequenceFlow attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>sourceRef: FlowNode</td>
<td>The FlowNode that the Sequence Flow is connecting from. For a Process: Of the types of FlowNode, only Activities, Gateways, and Events can be the source. However, Activities that are Event Sub-Processes are not allowed to be a source. For a Choreography: Of the types of FlowNode, only Choreography Activities, Gateways, and Events can be the source.</td>
</tr>
<tr>
<td>targetRef: FlowNode</td>
<td>The FlowNode that the Sequence Flow is connecting to. For a Process: Of the types of FlowNode, only Activities, Gateways, and Events can be the target. However, Activities that are Event Sub-Processes are not allowed to be a target. For a Choreography: Of the types of FlowNode, only Choreography Activities, Gateways, and Events can be the target.</td>
</tr>
<tr>
<td>conditionExpression: Expression [0..1]</td>
<td>An optional boolean Expression that acts as a gating condition. A token will only be placed on this Sequence Flow if this conditionExpression evaluates to true.</td>
</tr>
</tbody>
</table>
| isImmediate: boolean [0..1] | An optional boolean value specifying whether Activities or Choreography Activities not in the model containing the Sequence Flow can occur between the elements connected by the Sequence Flow. If the value is false, they MAY NOT occur. If the value is true, they MAY occur. Also see the isClosed attribute on Process, Choreography, and Collaboration. When the attribute has no value, the default semantics depends on the kind of model containing Sequence Flows:  
  • For non-executable Processes (public Processes and non-executable private Processes) and Choreographies no value has the same semantics as if the value were false.  
  • For an executable Processes no value has the same semantics as if the value were true.  
  • For executable Processes, the attribute MUST NOT be false. |

Flow Node

The FlowNode element is used to provide a single element as the source and target Sequence Flow associations (see Figure 8.35) instead of the individual associations of the elements that can connect to Sequence Flows (see the section above). Only the Gateway, Activity, Choreography Activity, and Event elements can connect to Sequence Flows and thus, these elements are the only ones that are sub-classes of FlowNode.

Since Gateway, Activity, Choreography Activity, and Event have their own attributes, model associations, and inheritances; the FlowNode element does not inherit from any other BPMN element. Table 8.52 presents the additional model associations of the FlowNode element:
8.3.14 Common Package XML Schemas

    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
8.4 Services

The Service package contains constructs necessary for modeling services, interfaces, and operations.

Figure 8.36 - The Service class diagram

8.4.1 Interface

An Interface defines a set of operations that are implemented by Services.

The Interface inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to RootElement. Table 8.65 presents the additional attributes and model associations of the Interface:
8.4.2 EndPoint

The actual definition of the service address is out of scope of BPMN 2.0. The EndPoint element is an extension point and extends from RootElement. The EndPoint element MAY be extended with endpoint reference definitions introduced in other specifications (e.g., WS-Addressing).

EndPoints can be specified for Participants.

8.4.3 Operation

An Operation defines Messages that are consumed and, optionally, produced when the Operation is called. It can also define zero or more errors that are returned when operation fails. The Operation inherits the attributes and model associations of BaseElement (see Table 8.5). Table 8.66 below presents the additional attributes and model associations of the Operation:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>operations: Operation [1..*]</td>
<td>This attribute specifies operations that are defined as part of the Interface. An Interface has at least one Operation.</td>
</tr>
<tr>
<td>callableElements: CallableElement [0..*]</td>
<td>The CallableElements that use this Interface.</td>
</tr>
<tr>
<td>implementationRef: Element [0..1]</td>
<td>This attribute allows to reference a concrete artifact in the underlying implementation technology representing that interface, such as a WSDL porttype.</td>
</tr>
</tbody>
</table>
### Service Package XML Schemas

</xsd:complexType>
9 Collaboration

Note – The contents of this chapter are REQUIRED for BPMN Choreography Modeling Conformance, BPMN Process Modeling Conformance, or for BPMN Complete Conformance. However, this chapter is NOT REQUIRED for BPMN Process Execution Conformance or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 2.

The Collaboration package contains classes which are used for modeling Collaborations, which is a collection of Participants shown as Pools, their interactions as shown by Message Flows, and MAY include Processes within the Pools and/or Choreographies between the Pools (see Figure 9.1). A Choreography is an extended type of Collaboration. When a Collaboration is defined it is contained in Definitions.

Figure 9.1 - Classes in the Collaboration package
The Collaboration element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship toRootElement. Table 9.1 presents the additional attributes and model associations for the Collaboration element:

Table 9.1 - Collaboration Attributes and Model Associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the Collaboration.</td>
</tr>
<tr>
<td>choreographyRef:</td>
<td>The choreographyRef model association defines the Choreographies that can be shown between the Pools of the Collaboration. A Choreography specifies a business contract (or the order in which messages will be exchanged) between interacting Participants. See page 325 for more details on Choreography. The participantAssociations (see below) are used to map the Participants of the Choreography to the Participants of the Collaboration. The MessageFlowAssociations (see below) are used to map the Message Flows of the Choreography to the Message Flows of the Collaboration. The conversationAssociations (see below) are used to map the Conversations of the Choreography to the Conversations of the Collaboration. Note that this attribute is not applicable for Choreography or GlobalConversation which are a subtypes of Collaboration. Thus, a Choreography cannot reference another Choreography.</td>
</tr>
<tr>
<td>CorrelationKey [0..*]</td>
<td>This association specifies CorrelationKeys used to associate Messages to a particular Collaboration.</td>
</tr>
<tr>
<td>conversationAssociations:</td>
<td>This attribute provides a list of mappings from the Conversations of a referenced Collaboration to the Conversations of another Collaboration. It is used when:</td>
</tr>
<tr>
<td>ConversationAssociation [0..*]</td>
<td>• When a Choreography is referenced by a Collaboration.</td>
</tr>
<tr>
<td>ConversationNode [0..*]</td>
<td>The conversations model aggregation relationship allows a Collaboration to contain Conversation elements, in order to group Message Flows of the Collaboration and associate correlation information, as is REQUIRED for the definitional Collaboration of a Process model. The Conversation elements will be visualized if the Collaboration is a Collaboration, but not for a Choreography.</td>
</tr>
<tr>
<td>ConversationLink [0..*]</td>
<td>This provides the Conversation Links that are used in the Collaboration.</td>
</tr>
<tr>
<td>Artifact [0..*]</td>
<td>This attribute provides the list of Artifacts that are contained within the Collaboration.</td>
</tr>
</tbody>
</table>
A set of Messages Flow of a particular Collaboration MAY belong to a Conversation. A Conversation is a set of Message Flows that share a particular purpose—i.e., they all relate to the handling of a single order (see page 125 for more information about Conversations).

### 9.1 Basic Collaboration Concepts

A **Collaboration** usually contains two (2) or more **Pools**, representing the **Participants** in the **Collaboration**. The **Message** exchange between the **Participants** is shown by a **Message Flow** that connects two (2) **Pools** (or the objects within the **Pools**). The **Messages** associated with the **Message Flows** MAY also be shown. See Figure 9.3, Figure 9.4, and Figure 9.5 for examples of **Collaborations**.

A **Pool** MAY be empty, a “black box,” or MAY show a **Process** within. **Choreographies** MAY be shown “in between” the **Pools** as they bisect the **Message Flows** between the **Pools**. All combinations of **Pools**, **Processes**, and a **Choreography** are allowed in a **Collaboration**.

### Table 9.1 - Collaboration Attributes and Model Associations

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>participants</td>
<td>This provides the list of <strong>Participants</strong> that are used in the <strong>Collaboration</strong>. <strong>Participants</strong> are visualized as <strong>Pools</strong> in a <strong>Collaboration</strong> and as <strong>Participant Bands</strong> in <strong>Choreography Activities</strong> in a <strong>Choreography</strong>.</td>
</tr>
</tbody>
</table>
| participantAssociations  | This attribute provides a list of mappings from the **Participants** of a referenced **Collaboration** to the **Participants** of another **Collaboration**. It is used in the following situations:  
|                          | • When a **Choreography** is referenced by the **Collaboration**.  
|                          | • When a **definitional Collaboration** for a **Process** is referenced through a **Call Activity** (and mapped to **definitional Collaboration** of the calling **Process**). |
| messageFlow              | This provides the list of **Message Flows** that are used in the **Collaboration**. **Message Flows** are visualized in **Collaboration** (as dashed line) and hidden in **Choreography**. |
| messageFlowAssociations  | This attribute provides a list of mappings for the **Message Flows** of the **Collaboration** to **Message Flows** of a referenced model. It is used in the following situation:  
|                          | • When a **Choreography** is referenced by a **Collaboration**. This allows the “wiring up” of the **Collaboration Message Flows** to the appropriate **Choreography Activities**. |
| IsClosed                 | A boolean value specifying whether **Message Flows** not modeled in the **Collaboration** can occur when the **Collaboration** is carried out.  
|                          | • If the value is **true**, they MAY NOT occur.  
|                          | • If the value is **false**, they MAY occur. |
9.1.1 Use of BPMN Common Elements

Some BPMN elements are common to both Process and Choreography, as well as Collaboration; they are used in these diagrams. The next few sections will describe the use of Messages, Message Flows, Participants, Sequence Flows, Artifacts, Correlations, Expressions, and Services in Choreography.

9.2 Pool and Participant

A Pool is the graphical representation of a Participant in a Collaboration. A Participant (see page 115) can be a specific PartnerEntity (e.g., a company) or can be a more general PartnerRole (e.g., a buyer, seller, or manufacturer). A Pool MAY or MAY NOT reference a Process. A Pool is NOT REQUIRED to contain a Process, i.e., it can be a “black box.”

- A Pool is a square-cornered rectangle that MUST be drawn with a solid single line (see Figure 9.2).
- The label for the Pool MAY be placed in any location and direction within the Pool, but MUST be separated from the contents of the Pool by a single line.
- If the Pool is a black box (i.e., does not contain a Process), then the label for the Pool MAY be placed anywhere within the Pool without a single line separator.
- One, and only one, Pool in a diagram MAY be presented without a boundary. If there is more than one Pool in the diagram, then the remaining Pools MUST have a boundary.

The use of text, color, size, and lines for a Pool MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
</tbody>
</table>

Figure 9.2 - A Pool

To help with the clarity of the Diagram, a Pool extends the entire length of the Diagram, either horizontally or vertically. However, there is no specific restriction to the size and/or positioning of a Pool. Modelers and modeling tools can use Pools in a flexible manner in the interest of conserving the “real estate” of a Diagram on a screen or a printed page.

A Pool acts as the container for the Sequence Flows between Activities (of a contained Process). The Sequence Flows can cross the boundaries between Lanes of a Pool (see page 313 for more details on Lanes), but cannot cross the boundaries of a Pool. That is, a Process is fully contained within the Pool. The interaction between Pools is shown through Message Flows.

Another aspect of Pools is whether or not there is any Activity detailed within the Pool. Thus, a given Pool MAY be shown as a “White Box,” with all details (e.g., a Process) exposed, or as a “Black Box,” with all details hidden. No Sequence Flows are associated with a “Black Box” Pool, but Message Flows can attach to its boundaries (see Figure 9.3).
For a “White Box” Pool, the Activities within are organized by Sequence Flows. Message Flows can cross the Pool boundary to attach to the appropriate Activity (see Figure 9.4).
A **Collaboration** can contain two (2) or more **Pools** (i.e., **Participants**). However, a **Process** that represents the work performed from the point of view of the modeler or the modeler's organization can be considered "internal" and is NOT REQUIRED to be surrounded by the boundary of the **Pool**, while the other **Pools** in the Diagram MUST have their boundary (see Figure 9.5).

![Figure 9.5 - Main (Internal) Pool without boundaries](image)

**BPMN** specifies a marker for **Pools**: a **multi-instance** marker May be displayed for a **Pool** (see Figure 9.6). The marker is used if the **Participant** defined for the **Pool** is a **multi-instance Participant**. See page 118 for more information on **Participant** multiplicity.

- The marker for a **Pool** that is a **multi-instance** MUST be a set of three vertical lines in parallel.
- The marker, if used, MUST be centered at the bottom of the shape.
9.2.1 Participants

A Participant represents a specific PartnerEntity (e.g., a company) and/or a more general PartnerRole (e.g., a buyer, seller, or manufacturer) that are Participants in a Collaboration. A Participant is often responsible for the execution of the Process enclosed in a Pool; however, a Pool MAY be defined without a Process.

Figure 9.7 displays the class diagram of the Participant and its relationships to other BPMN elements. When Participants are defined they are contained within a Collaboration, which includes the sub-types of Choreography, GlobalConversation, or GlobalChoreographyTask.
Figure 9.7 - The Participant Class Diagram

The Participant element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 9.2 presents the additional attributes and model associations for the Participant element:
PartnerEntity

A PartnerEntity is one of the possible types of Participant (see the section above).

The PartnerEntity element inherits the attributes and model associations of BaseElement (see Figure 8.5). Table 9.3 presents the additional attributes and model associations for the PartnerEntity element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>Name is a text description of the Participant. The name of the Participant can be displayed directly or it can be substituted by the associated PartnerRole or PartnerEntity. Potentially, both the PartnerEntity name and PartnerRole name can be displayed for the Participant.</td>
</tr>
<tr>
<td>processRef: Process [0..1]</td>
<td>The processRef attribute identifies the Process that the Participant uses in the Collaboration. The Process will be displayed within the Participant’s Pool.</td>
</tr>
<tr>
<td>partnerRoleRef: PartnerRole [0..*]</td>
<td>The partnerRoleRef attribute identifies a PartnerRole that the Participant plays in the Collaboration. Both a PartnerRole and a PartnerEntity MAY be defined for the Participant. This attribute is derived from the participantRefs of PartnerRole.</td>
</tr>
<tr>
<td>partnerEntityRef: PartnerEntity [0..*]</td>
<td>The partnerEntityRef attribute identifies a PartnerEntity that the Participant plays in the Collaboration. Both a PartnerRole and a PartnerEntity MAY be defined for the Participant. This attribute is derived from the participantRefs of PartnerEntity.</td>
</tr>
<tr>
<td>interfaceRef: Interface [0..*]</td>
<td>This association defines Interfaces that a Participant supports. The definition of Interfaces is provided on page 104.</td>
</tr>
<tr>
<td>participantMultiplicity: participant-Multiplicity [0..1]</td>
<td>The participantMultiplicityRef model association is used to define Participants that represent more than one (1) instance of the Participant for a given interaction. See the next section for more details on ParticipantMultiplicity.</td>
</tr>
<tr>
<td>endPointRefs: EndPoint [0..*]</td>
<td>This attribute is used to specify the address (or endpoint reference) of concrete services realizing the Participant.</td>
</tr>
</tbody>
</table>

Table 9.3 – PartnerEntity attributes
PartnerRole

A PartnerRole is one of the possible types of Participant (see the section above).

The PartnerRole element inherits the attributes and model associations of BaseElement (see Figure 8.5). Table 9.4 presents the additional attributes and model associations for the PartnerRole element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the PartnerRole.</td>
</tr>
<tr>
<td>participantRef: Participant [0..*]</td>
<td>Specifies how the PartnerRole participates in Collaborations and Choreographies.</td>
</tr>
</tbody>
</table>

ParticipantMultiplicity

ParticipantMultiplicity is used to define the multiplicity of a Participant.

For example, a manufacturer can request a quote from multiple suppliers in a Collaboration.

![Figure 9.8 - A Pool with a Multiple Participant](image)

The following figure shows the Participant class diagram.

![Figure 9.9 - The Participant Multiplicity class diagram](image)
The multi-instance marker will be displayed in bottom center of the Pool (Participant - see Figure 9.9, above), or the Participant Band of a Choreography Activity (see page 331), when the ParticipantMultiplicity is associated with the Participant, and the maximum attribute is either not set, or has a value of two (2) or more.

Table 9.5 presents the attributes for the ParticipantMultiplicity element:

Table 9.5 – ParticipantMultiplicity attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>minimum: integer = 0</td>
<td>The minimum attribute defines minimum number of Participants that MUST be involved in the Collaboration. If a value is specified in the maximum attribute, it MUST be greater or equal to this minimum value.</td>
</tr>
<tr>
<td>maximum: integer [0..1] = 1</td>
<td>The maximum attribute defines maximum number of Participants that MAY be involved in the Collaboration. The value of maximum MUST be one (1) or greater, AND MUST be equal or greater than the minimum value.</td>
</tr>
</tbody>
</table>

Table 9.6 presents the Instance attributes of the ParticipantMultiplicity element:

Table 9.6 – ParticipantMultiplicity Instance attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>numParticipants: integer [0..1]</td>
<td>The current number of the multiplicity of the Participant for this Choreography or Collaboration Instance.</td>
</tr>
</tbody>
</table>

ParticipantAssociation

These elements are used to do mapping between two elements that both contain Participants. There are situations where the Participants in different diagrams can be defined differently because they were developed independently, but represent the same thing. The ParticipantAssociation provides the mechanism to match up the Participants.

A ParticipantAssociation is used when an (outer) diagram with Participants contains an (inner) diagram that also has Participants. There are four (4) usages of ParticipantAssociation. It is used when:

- A Collaboration references a Choreography for inclusion between the Collaboration’s Pools (Participants). The Participants of the Choreography (the inner diagram) need to be mapped to the Participants of the Collaboration (the outer diagram).

- A Call Conversation references a Collaboration or GlobalConversation. Thus, the Participants of the Collaboration or GlobalConversation (the inner diagram) need to be mapped to the Participants referenced by the Call Conversation (the outer element). Each Call Conversation contains its own set of ParticipantAssociations.

- A Call Choreography references a Choreography or GlobalChoreographyTask. Thus, the Participants of the Choreography or GlobalChoreographyTask (the inner diagram) need to be mapped to the Participants referenced by the Call Choreography (the outer element). Each Call Choreography contains its own set of ParticipantAssociations.
• A **Call Activity** within a **Process** that has a **definitional Collaboration** references another **Process** that also has a **definitional Collaboration**. The **Participants** of the **definitional Collaboration** of the called **Process** (the inner diagram) need to be mapped to the **Participants** of the **definitional Collaboration** of the calling **Process** (the outer diagram).

A **ParticipantAssociation** can be owned by the outer diagram or one its elements. Figure 9.10 shows the class diagram for the **ParticipantAssociation** element.

![ParticipantAssociation class diagram](image)

**Figure 9.10 - ParticipantAssociation class diagram**

The **ParticipantAssociation** element inherits the attributes and model associations of **BaseElement** (see Table 8.5). Table 9.7 presents the additional model associations for the **ParticipantAssociation** element:
9.2.2 Lanes

A Lane is a sub-partition within a Process (often within a Pool) and will extend the entire length of the Process level, either vertically (see Figure 10.123) or horizontally (see Figure 10.124). See page 313 for more information on Lanes.

9.3 Message Flow

A Message Flow is used to show the flow of Messages between two Participants that are prepared to send and receive them.

- A Message Flow MUST connect two separate Pools. They connect either to the Pool boundary or to Flow Objects within the Pool boundary. They MUST NOT connect two objects within the same Pool.
- A Message Flow is a line with an open circle line start and an open arrowhead line end that MUST be drawn with a dashed single line (see Figure 9.11).
- The use of text, color, size, and lines for a Message Flow MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

![Message Flow Diagram]

Figure 9.11 - A Message Flow

In Collaboration Diagrams (the view showing the Choreography Process Combined with Orchestration Processes), a Message Flow can be extended to show the Message that is passed from one Participant to another (see Figure 9.12).

Table 9.7 – ParticipantAssociation model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>innerParticipantRef</td>
<td>This attribute defines the Participant of the referenced element (e.g., a Choreography to be used in a Collaboration) that will be mapped to the parent element (e.g., the Collaboration).</td>
</tr>
<tr>
<td>outerParticipantRef</td>
<td>This attribute defines the Participant of the parent element (e.g., a Collaboration references a Choreography) that will be mapped to the referenced element (e.g., the Choreography).</td>
</tr>
</tbody>
</table>
If a **Choreography** is included in the **Collaboration**, then the **Message Flow** will “pass-through” a **Choreography Task** as it connects from one **Participant** to another (see Figure 9.13).

**Figure 9.12 - A Message Flow with an Attached Message**

**Figure 9.13 - A Message Flow passing through a Choreography Task**
Figure 9.14 displays the class diagram of a Message Flow and its relationships to other BPMN elements. When a Message Flow is defined it is contained either within a Collaboration, a Choreography, or a GlobalChoreographyTask.

The Message Flow element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 9.8 presents the additional attributes and model associations for the Message Flow element:
9.3.1 Interaction Node

The InteractionNode element is used to provide a single element as the source and target Message Flow associations (see Figure 9.14, above) instead of the individual associations of the elements that can connect to Message Flows (see the section above). Only the Pool/Participant, Activity, and Event elements can connect to Message Flows. The InteractionNode element is also used to provide a single element for source and target of Conversation Links, see page 134.

The InteractionNode element does not have any attributes or model associations and does not inherit from any other BPMN element. Since Pools/Participants, Activities, and Events have their own attributes, model associations, and inheritances, additional attributes and model associations for the InteractionNode element are not necessary.

9.3.2 Message Flow Associations

These elements are used to do mapping between two elements that both contain Message Flows. The MessageFlowAssociation provides the mechanism to match up the Message Flows.

A MessageFlowAssociation is used when an (outer) diagram with Message Flows contains an (inner) diagram that also has Message Flows. It is used when:

- A Collaboration references a Choreography for inclusion between the Collaboration's Pools (Participants). The Message Flows of the Choreography (the inner diagram) need to be mapped to the Message Flows of the Collaboration (the outer diagram).

- A Collaboration references a Conversation that contains Message Flows. The Message Flows of the Conversation can serve as a partial requirement for the Collaboration. Thus, the Message Flows of the Conversation (the inner diagram) need to be mapped to the Message Flows of the Collaboration (the outer diagram).

- A Choreography references a Conversation that contains Message Flows. The Message Flows of the Conversation can serve as a partial requirement for the Choreography. Thus, the Message Flows of the Conversation (the inner diagram) need to be mapped to the Message Flows of the Choreography (the outer diagram).

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>Name is a text description of the Message Flow.</td>
</tr>
<tr>
<td>sourceRef: InteractionNode</td>
<td>The InteractionNode that the Message Flow is connecting from. Of the types of InteractionNode, only Pools/Participants, Activities, and Events can be the source of a Message Flow.</td>
</tr>
<tr>
<td>targetRef: InteractionNode</td>
<td>The InteractionNode that the Message Flow is connecting to. Of the types of InteractionNode, only Pools/Participants, Activities, and Events can be the target of a Message Flow.</td>
</tr>
<tr>
<td>messageRef: Message [0..1]</td>
<td>The messageRef model association defines the Message that is passed via the Message Flow. See page 93 for more details.</td>
</tr>
</tbody>
</table>
Figure 9.15 shows the class diagram for the MessageFlowAssociation element.

The MessageFlowAssociation element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 9.9 presents the additional model associations for the MessageFlowAssociation element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>innerMessageFlowRef: Message Flow</td>
<td>This attribute defines the Message Flow of the referenced element (e.g., a Choreography to be used in a Collaboration) that will be mapped to the parent element (e.g., the Collaboration).</td>
</tr>
<tr>
<td>outerMessageFlowRef: Message Flow</td>
<td>This attribute defines the Message Flow of the parent element (e.g., a Collaboration references a Choreography) that will be mapped to the referenced element (e.g., the Choreography).</td>
</tr>
</tbody>
</table>

9.4 Conversations

The Conversation diagram is particular usage of and an informal description of a Collaboration diagram. In general, it is a simplified version of Collaboration, but Conversation diagrams do maintain all the features of a Collaboration. In particular, Processes can appear within the Participants (Pools) of Conversation diagrams, to show how Conversation and Activities are related.

The view includes two (2) additional graphical elements that do not exist in other BPMN views:

- Conversation Node elements (Conversation, Sub-Conversation, and Call Conversation)
- A Conversation Link
A **Conversation** is a logical grouping of **Message** exchanges (**Message Flows**) that can share a **Correlation**. A **Conversation** is the logical relation of **Message** exchanges. The logical relation, in practice, often concerns a business object(s) of interest, e.g., “Order,” “Shipment and Delivery,” and “Invoice.” Hence, a **Conversation** is associated with a set of name-value pairs, or a **Correlation Key** (e.g., “Order Identifier,” “Delivery Identifier”), which is recorded in the **Messages** that are exchanged. In this way, a **Message** can be routed to the specific **Process instance** responsible for receiving and processing the **Message**.

Figure 9.16 shows a simple example of a **Conversation** diagram.

![Figure 9.16 - A Conversation diagram](image)

Figure 9.17 shows a variation of the example above where the **Conversation** node has been expanded into its component **Message Flows**. Note that the diagram looks the same as a simple **Collaboration** diagram (as in Figure 9.3, above).

![Figure 9.17 - A Conversation diagram where the Conversation is expanded into Message Flows](image)

**Message** exchanges are related to each other and reflect distinct business scenarios. The relation is sometimes simple, e.g., a request followed by a response (and can be described as part of a structural interface of a service, e.g., as a WSDL operation definition). However for commercial business transactions managed through **Business Processes**, the relation can be complex, involving long-running, reciprocal **Message** exchanges, and that could extend beyond bilateral to complex, multilateral **Collaborations**. For example, in logistics, stock replenishments involve the following types scenarios: creation of sales orders; assignment of carriers for shipments combining different sales orders; crossing customs/quarantine; processing payment and investigating exceptions.
In addition to an orchestration Process, Conversations are relevant to a Choreography, but the Conversations are not visualized in a Choreography. The difference is that a Choreography provides a multi-party perspective of a Conversation. This is because the Message exchanges modeled using Choreography Activities concern multiple Participants, unlike an orchestration Process where the Message sending and receiving elements relate to one Participant only. Other than the difference in perspective, the notion of Conversation remains the same across Choreography and orchestration - and the Message exchanges of a Conversation will ultimately be executed through an orchestration Process.

Since Collaboration provides a top-down, design-time modeling perspective for Message exchanges and their Conversations, an abstracted view of the all Conversations pertaining to a domain being modeled is available through a Conversation diagram. A Conversation diagram, as depicted in Figure 9.18, shows Conversations (as hexagons) between Participants. This provides a “bird’s eye” perspective of the different Conversations which relate to the domain.

Figure 9.18 - Conversation diagram depicting several conversations between Participants in a related domain

Figure 9.18, above, depicts 13 distinct Conversations between collaborating Participants in a logistics domain. As examples, Retailer and Supplier are involved in a Delivery Negotiations Conversation, and Consignee converses with Retailer and Supplier through Delivery/Dispatch Plan and Shipment Schedule Conversations respectively. More than two participants MAY be involved in a Conversation, e.g., Consignee, Consolidator and Shipper in Detailed Shipment
Schedule. The association of Participants to a Conversation are constrained to indicate whether one or many of Participants are involved. For example, one instance of Retailer converses with one instance of Supplier for Deliver Negotiations. However, one instance of Shipper converses with multiple instances of Carrier (indicated by the multi-instance symbol of the Pool for Carrier) for Carrier Planning. Note, multiplicity in constraints of Conversation diagrams means one or more (not zero or more).

The behavior of different Conversations is modeled through separate Choreographies, detailing the Message exchange sequences. In practice, Conversations which are closely related could be combined in the same Choreography models – e.g., a Message exchange in the Delivery Negotiation leads to Shipment Schedule, Delivery Planning and Delivery/Dispatch Conversations and these could be combined together in the same Choreography. Alternatively, they could be separated in different models.

Figure 9.19 shows a subset of the larger Conversation diagram of Figure 9.18, above. Figure 9.20 and Figure 9.21 show the drill down into the "Delivery Negotiations" Sub-Conversation. This expands the Conversation with the Message Flows, providing a structural view of a Conversation without the “clutter” of sequencing details in the same diagram. Figure 9.19 also indicates the CorrelationKey involved in the Message Flows of the Conversation. For example, Order Id is necessary for in all Messages of Message Flows in Delivery Negotiation. In addition, some Message Flows also require Variation Id (for dealing with shipment variations on a per line item basis).

![Figure 9.19 - An example of a Sub-Conversation](image)

Figure 9.20 shows a how the Sub-Conversation of Figure 9.19, above, is expanded into a set of Message Flows and a lower-level Conversation.
Figure 9.20 - An example of a Sub-Conversation expanded to a Conversation and Message Flow

Figure 9.21 shows how the Conversation of Figure 9.20, above, is also expanded into a set of Message Flows, combined with the previous Message Flows. Note that the newly exposed Message Flows of the lower-level Conversation will be correlated by the CorrelationKey of both the lower-level Conversation (Variation Id) and the higher-level Sub-Conversations (Order Id).

Figure 9.21 - An example of a Sub-Conversation that is fully expanded

In Figure 9.19, above, a hierarchical structure of Conversations can be seen with one set of Message Flows occurring within another in a parent-child relationship. In particular, after Planned Order Variations (keyed on Order Id) at the parent, a number of Message Flows of the child follow till Retailer Order and Delivery Variations Ack (keyed on Variation Id and Order Id). The remaining Message Flows (keyed on Order Id) are at the parent level. The child Conversation, as such, is part of the parent Conversation. Nesting is indicated graphically on a Conversation symbol (by a “+”), indicating a Sub-Conversation or a Call Conversation calling a Collaboration. Nesting can go to an arbitrary number of levels.
A common dependency between Conversations is overlap. Overlap occurs when two or more Conversations have some Message exchanges in common but not others. As an example in Figure 9.18, above, a Message is sent as part of Detailed Shipment Schedule (keyed on Carrier Schedule Id) to trigger Delivery Monitoring (keyed on Shipment Id). During Delivery Monitoring, Message could be sent to Detailed Shipment Schedule (to request modifications when transportation exceptions occur).

Splits and joins are special types of overlap scenarios. A Conversation split arises when, as part of a Conversation, a message is exchanged between two or more Participants that at the same time spawns a new, distinct Conversation (either between the same set of Participants or another set). Additionally, no further Message exchanges are shared by the split Conversations as well as no subsequent merges of them occur. An example is Delivery Planning which leads to Carrier Planning and Special Cover. A Conversation join occurs when several Conversations are merged into one Conversation and no further Message exchanges occur in the original Conversations, i.e., these Conversations are finalized. The generalization of a split and join is a Conversation refactor where Conversations are split into parallel Conversations and then are merged at a later point in time.

### 9.4.1 Conversation Node

ConversationNode is the abstract super class for all elements that can comprise the Conversation elements of a Collaboration diagram, which are Conversation (see page 132), Sub-Conversation (see page 132), and Call Conversation (see page 133).
Figure 9.22 - Metamodel of ConversationNode Related Elements

ConversationNodes are linked to and from Participants using Conversation Links (see page 134).

The ConversationNode element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 9.10 presents the additional attributes and model associations for the ConversationNode element:
### 9.4.2 Conversation

A **Conversation** is an atomic element for a **Conversation (Collaboration)** diagram. It represents a set of **Message Flows** grouped together based on a concept and/or a **CorrelationKey**. A **Conversation** will involve two (2) or more **Participants**.

- A **Conversation** is a hexagon that MUST be drawn with a single thin line (see Figure 9.23).

![Figure 9.23 – A Communication element](image)

The **Conversation** element inherits the attributes and model associations of **ConversationNode** (see Table 9.10), but does not contain any additional attributes or model associations.

### 9.4.3 Sub-Conversation

A **Sub-Conversation** is a **ConversationNode** that is a hierarchical division within the parent **Collaboration**. A **Sub-Conversation** is a graphical object within a **Collaboration**, but it also can be “opened up” to show the lower-level details of the **Conversation**, which consist of **Message Flows**, **Conversations**, and/or other **Sub-Conversations**. The **Sub-Conversation** shares the **Participants** of its parent **Conversation**.

- A **Sub-Conversation** is a hexagon that MUST be drawn with a single thin line (see Figure 9.24).
- The **Sub-Conversation** marker MUST be a small square with a plus sign (+) inside. The square MUST be positioned at the bottom center of the shape.

### Table 9.10 – ConversationNode Model Associations

<tbody>
<tr>
<td>name: string [0..1]</td>
<td>Name is a text description of the ConversationNode element.</td>
</tr>
<tr>
<td>participantRefs: Participant [2..*]</td>
<td>This provides the list of Participants that are used in the ConversationNode from the list provided by the ConversationNode’s parent Conversation. This reference is visualized through a Conversation Link (see page 134).</td>
</tr>
<tr>
<td>messageFlowRefs: MessageFlow [0..*]</td>
<td>A reference to all Message Flows (and consequently Messages) grouped by a Conversation element.</td>
</tr>
<tr>
<td>correlationKeys: CorrelationKey [0..*]</td>
<td>This is a list of the ConversationNode’s CorrelationKeys, which are used to group Message Flows for the ConversationNode.</td>
</tr>
</tbody>
</table>
The **Sub-Conversation** element inherits the attributes and model associations of **ConversationNode** (see Table 9.10). Table 9.11 presents the additional model associations for the **Sub-Conversation** element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>conversationNodes:</td>
<td>The <strong>ConversationNodes</strong> model aggregation relationship allows a <strong>Sub-Conversation</strong> to contain other <strong>ConversationNodes</strong>, in order to group <strong>Message Flows</strong> of the <strong>Sub-Conversation</strong> and associate correlation information.</td>
</tr>
<tr>
<td>ConversationNode [0..*]</td>
<td></td>
</tr>
</tbody>
</table>

### 9.4.4 Call Conversation

A **Call Conversation** identifies a place in the **Conversation** (**Collaboration**) where a global **Conversation** or a **GlobalConversation** is used.

- If the **Call Conversation** calls a **GlobalConversation**, then the shape will be the same as a **Conversation**, but the boundary of the shape will **MUST** have a thick line (see Figure 9.25).
- If the **Call Conversation** calls a **Collaboration**, then the shape will be the same as a **Sub-Conversation**, but the boundary of the shape will **MUST** have a thick line (see Figure 9.26).

---

The **Call Conversation** element inherits the attributes and model associations of **ConversationNode** (see Table 9.10). Table 9.12 presents the additional model associations for the **Call Conversation** element:
### 9.4.5 Global Conversation

A GlobalConversation is a reusable, atomic Conversation definition that can be called from within any Collaboration by a Call Conversation.

The GlobalConversation element inherits the attributes and model associations and Collaboration (see Table 9.1), but does not have any additional attributes or model associations.

A GlobalConversation is a restricted type of Collaboration, it is an "empty Collaboration."

- A GlobalConversation MUST NOT contain any ConversationNodes.

Since a GlobalConversation does not have any Flow Elements, it does not require MessageFlowAssociations, ParticipantAssociations, or ConversationAssociations or Artifacts.

It is basically a set of Participants, Message Flows, and CorrelationKeys intended for reuse. Also, the Collaboration attribute choreographyRef is not applicable to GlobalConversation.

### 9.4.6 Conversation Link

Conversation Links are used to connect ConversationNodes to and from Participants (Pools -- see Figure 9.27).

- Conversation Links MUST be drawn with double thin lines.
Processes can appear in the Participants (Pools) of Conversation diagrams, as shown in Figure 9.28. The invoicing and ordering Conversations have links into Activities and Events of the Process in the Order Processor. The other two Conversations do not have their links "expanded". Conversation Links into Activities that are not Send or Receive Tasks indicate that the Activity will send or receive Messages of the Conversation at some level of nesting.
Figure 9.28 – Conversation links to Activities and Events
The **Conversation Link** element inherits the attributes and model associations of **BaseElement** (see Table 8.5). Table 9.13 presents the additional attributes and model associations for the **Conversation Link** element:

**Table 9.13 – Conversation Link Attributes and Model Associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>This attribute specifies the name of the Conversation Link.</td>
</tr>
<tr>
<td>sourceRef: InteractionNode</td>
<td>The InteractionNode that the Conversation Link is connecting from. A Conversation Link MUST connect to exactly one ConversationNode. If the sourceRef is not a ConversationNode, then the targetRef MUST be a ConversationNode.</td>
</tr>
<tr>
<td>targetRef: InteractionNode</td>
<td>The InteractionNode that the Conversation Link is connecting to. A Conversation Link MUST connect to exactly one ConversationNode. If the targetRef is not a ConversationNode, then the sourceRef MUST be a ConversationNode.</td>
</tr>
</tbody>
</table>

**Conversation Links** for **Call Conversations** show the names of **Participants** in nested **Collaboration** or global **Collaborations**, as identified by **ParticipantAssociations**. For example, Figure 9.30 has a **Collaboration** on the left with a **Call Conversations** to a **Collaboration** on the right. The **Conversation Links** on the left indicate...
which Participants in the called Collaboration on the right correspond to which Participants in the calling Collaboration on the left. For example, the Credit Agency Participants on the right corresponds to the Financial Company Participant on the left. ParticipantAssociations (not shown) tie each Participant in the Collaboration on the left to a Participant in the Collaboration on the right. They can be used to show the names of Participants in nested Collaboration or global Collaborations.

Figure 9.30 – Call Conversation Links

9.4.7 Conversation Association

A ConversationAssociation is used within Collaborations and Choreographies to apply a reusable Conversation to the Message Flows of those diagrams.

A ConversationAssociation is used when a diagram references a Conversation to provide Message correlation information and/or to logically group Message Flows. It is used when:

- A Collaboration references a Choreography for inclusion between the Collaboration’s Pools (Participants). The ConversationNodes of the Choreography (the inner diagram) need to be mapped to the ConversationNodes of the Collaboration (the outer diagram).
The ConversationAssociation element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 9.14 presents the additional model associations for the ConversationAssociation element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>innerConversationNodeRef:</td>
<td>This attribute defines the ConversationNodes of the referenced element (e.g., a Choreography to be used in a Collaboration) that will be mapped to the parent element (e.g., the Collaboration).</td>
</tr>
<tr>
<td>ConversationNode [0..1]</td>
<td></td>
</tr>
<tr>
<td>outerConversationNodeRef:</td>
<td>This attribute defines the ConversationNodes of the parent element (e.g., a Collaboration references a Choreography) that will be mapped to the referenced element (e.g., the Choreography).</td>
</tr>
<tr>
<td>ConversationNode [0..*]</td>
<td></td>
</tr>
</tbody>
</table>

### 9.4.8 Correlations

Correlations are the mechanism that is used to assign the Messages to the proper Process instance, and can be defined for the Message Flows that belong to the a Conversation. Correlations can be used to specify Conversations between Processes that follow a fairly simple Conversation pattern in the sense that:

- The conceptual data of the Conversation is well known and defined by the participating Processes. However this doesn’t mandate that underlying type systems are identical. It is sufficient that the data is known “conceptually” on a (potentially very high) business level.
- A Conversation takes place by means of simple Message exchange between Processes, no additional agreements MUST be considered.
- There exists send and receive Tasks accepting the conceptual data of the Conversation. (An Order send by a Task...
of a Process should be received by at least one Task of the participating Process).

• The correlation itself is defined in terms of correlation fields, which denote a subset of the conceptual data that should be used for the correlation. (For example, if the conceptual data comprises of an order than the correlation field might be denoted by the order ID).

In some applications it is useful to allow more Messages to be sent between Participants when a Collaboration is carried out than are contained in the Collaboration model. This enables Participants to exchange other Messages as needed without changing the Collaboration. If the isClosed attribute of a Collaboration has a value of false or no value, then Participants MAY send Messages to each other without additional Message Flows in the Collaboration. If the isClosed attribute of a Collaboration has a value of true, then Participants MAY NOT send Messages to each other without additional Message Flows in the Collaboration. If a Collaboration contains a Choreography, then the value of the isClosed attribute MUST be the same in both. Restrictions on unmodeled messaging specified with isClosed apply only under the Collaboration containing the restriction. PartnerEntities and PartnerRoles of the Participants MAY send Messages to each other under other Choreographies, Collaborations, and Conversations.

9.5 Process Within Collaboration

Processes can be included in a Collaboration diagram. A Participant/Pool within the Collaboration can contain a Process (but they are NOT REQUIRED). An example of this is shown in Figure 9.4, above.

When a Lane (in a Process) represents a Conversation, the Flow Elements in the Lane (or elements nested or called in them) that send or receive Messages MUST do so as part of the Conversation represented by the Lane.

9.6 Choreography within Collaboration

Choreographies can be included in a Collaboration diagram. A Collaboration specifies how the Participants and Message Flows in the Choreography are matched up with the Participants and Message Flows in the Collaboration. A Collaboration uses ParticipantAssociations and MessageFlowAssociations for this purpose.

To handle the Participants, the innerParticipant of a ParticipantAssociation refers to a Participant in the Choreography, while the outerParticipant refers to a Participant in the Collaboration containing the Choreography. This mapping matches the Participant Bands of the Choreography Activities in the Choreography to the Pools in the Collaboration. Thus, the names in the Participant Bands are NOT REQUIRED (see Figure 9.32).
To handle **Message Flows**, the `innerMessageFlow` of a `MessageFlowAssociation` refers to a `Message Flow` in the **Choreography**, while the `outerMessageFlow` refers to a `Message Flow` in the **Collaboration** containing the **Choreography**. This mapping matches the **Message Flows** of the **Choreography** (which are not visible) to the **Message Flows** in the **Collaboration** (which are visible). This allows the **Message Flows** of the **Collaboration** to be “wired up” through the appropriate **Choreography Activity** in the **Choreography** (see Figure 9.32).

The **ParticipantAssociations** might be derived from the `partnerEntities` or `partnerRoles` of the **Participants**. For example, if a **Choreography Activity** has a **Participant** with the same `partnerEntity` as a **Participant** in the **Collaboration** containing the **Choreography**, then these two (2) **Participants** could be assumed to be the inner and outer **Participants** of a **ParticipantAssociation**. Similarly, **Message Flows** that reference the same **Message** in a **Call Choreography Activity** and the **Collaboration**, could be automatically synchronized by a **MessageFlowAssociation**, if only one **Message Flow** has that **Message**.

10 Process

Note – The content of this chapter is REQUIRED for BPMN Process Modeling Conformance or for BPMN Complete Conformance. However, this chapter is NOT REQUIRED for BPMN Process Choreography Conformance, BPMN Process Execution Conformance, or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 2.

A Process describes a sequence or flow of Activities in an organization with the objective of carrying out work. In BPMN a Process is depicted as a graph of Flow Elements, which are a set of Activities, Events, Gateways, and Sequence Flows that define finite execution semantics (see Figure 10.1). Processes can be defined at any level from enterprise-wide Processes to Processes performed by a single person. Low-level Processes can be grouped together to achieve a common business goal.

Figure 10.1 - An Example of a Process

Note that BPMN uses the term Process specifically to mean a set of flow elements. It uses the terms Collaboration and Choreography when modeling the interaction between Processes.

The Process package contains classes which are used for modeling the flow of Activities, Events, and Gateways, and how they are sequenced within a Process (see Figure 10.2). When a Process is defined it is contained within Definitions.
Figure 10.2 - Process class diagram

A **Process** is a **CallableElement**, allowing it to be referenced and reused by other **Processes** via the **Call Activity** construct. In this capacity, a **Process** **MAY** reference a set of **Interfaces** that define its external behavior.

A **Process** is a reusable element and can be imported and used within other **Definitions**.

Figure 10.3 shows the details of the attributes and model associations of a **Process**.
The Process element inherits the attributes and model associations of CallableElement (see Table 10.24) and of FlowElementContainer (see Table 8.45). Table 10.1 presents the additional attributes and model associations of the Process element:

Table 10.1 – Process Attributes & Model Associations

</tr>
<tr>
<td>supports</td>
<td>Modelers can declare that they intend all executions or performances of one Process to also be valid for another Process. This means they expect all the executions or performances of the first Processes to also follow the steps laid out in the second Process.</td>
</tr>
<tr>
<td>properties</td>
<td>Modeler-defined properties MAY be added to a Process. These properties are contained within the Process. All Tasks and Sub Processes SHALL have access to these properties.</td>
</tr>
<tr>
<td>resources</td>
<td>Defines the resource that will perform or will be responsible for the Process. The resource, e.g., a performer, can be specified in the form of a specific individual, a group, an organization role or position, or an organization. Note that the assigned resources of the Process does not determine the assigned resources of the Activities that are contained by the Process. See more details about resource assignment on page 158.</td>
</tr>
</tbody>
</table>
In addition, a Process instance has attributes whose values MAY be referenced by Expressions (see Table 10.2). These values are only available when the Process is being executed.

### 10.1 Basic Process Concepts

#### 10.1.1 Types of BPMN Processes

**Business Process** modeling is used to communicate a wide variety of information to a wide variety of audiences. BPMN is designed to cover many types of modeling and allows the creation of end-to-end Business Processes. There are three basic types of BPMN Processes:

- **Private Non-executable (internal) Business Processes**
- **Private Executable (internal) Business Processes**
- **Public Processes**

**Private (Internal) Business Processes** are those internal to a specific organization. These Processes have been generally called workflow or BPM Processes (see Figure 10.4). Another synonym typically used in the Web services area is the Orchestration of services. There are two (2) types of private Processes: executable and non-executable. An executable Process is a Process that has been modeled for the purpose of being executed according to the semantics defined in
Chapter 14 (see page 440). Of course, during the development cycle of the Process, there will be stages where the Process does not have enough detail to be “executable.” A non-executable Process is a private Process that has been modeled for the purpose of documenting Process behavior at a modeler-defined level of detail. Thus, information needed for execution, such as formal condition Expressions are typically not included in a non-executable Process.

If a swimlanes-like notation is used (e.g., a Collaboration, see below) then a private Business Process will be contained within a single Pool. The Process flow is therefore contained within the Pool and cannot cross the boundaries of the Pool. The flow of Messages can cross the Pool boundary to show the interactions that exist between separate private Business Processes.

![Diagram of a private Business Process]

**Figure 10.4 - Example of a private Business Process**

**Public Processes**

A public Process represents the interactions between a private Business Process and another Process or Participant (see Figure 10.5). Only those Activities that are used to communicate to the other Participant(s), plus the order of these Activities, are included in the public Process. All other “internal” Activities of the private Business Process are not shown in the public Process. Thus, the public Process shows to the outside world the Messages, and the order of these Messages, that are needed to interact with that Business Process. Public Processes can be modeled separately or within a Collaboration to show the flow of Messages between the public Process Activities and other Participants. Note that the public type of Process was named “abstract” in BPMN 1.2.

![Diagram of a public Process]

**Figure 10.5 - Example of a public Process**

### 10.1.2 Use of BPMN Common Elements

Some BPMN elements are common to both Process and Choreography, as well as Collaboration; they are used in these diagrams. The next few sections will describe the use of Messages, Message Flows, Participants, Sequence Flows, Artifacts, Correlations, Expressions, and Services in Choreography.
The key graphical elements of **Gateways** and **Events** are also common to both **Choreography** and **Process**. Since their usage has a large impact, they are described in major sections of this chapter (see page 240 for **Events** and page 295 for **Gateways**).

### 10.2 Activities

An **Activity** is work that is performed within a **Business Process**. An **Activity** can be atomic or non-atomic (compound). The types of **Activities** that are a part of a **Process** are: **Task**, **Sub-Process**, and Call **Activity**, which allows the inclusion of re-usable **Tasks** and **Processes** in the diagram. However, a **Process** is not a specific graphical object. Instead, it is a set of graphical objects. The following sections will focus on the graphical objects **Sub-Process** and **Task**.

**Activities** represent points in a **Process** flow where work is performed. They are the executable elements of a **BPMN Process**.

The **Activity** class is an abstract element, sub-classing from **FlowElement** (as shown in Figure 10.6).

Concrete sub-classes of **Activity** specify additional semantics above and beyond that defined for the generic **Activity**.

![Activity class diagram](image)

**Figure 10.6 - Activity class diagram**

The **Activity** class is the abstract super class for all concrete **Activity** types.
The Activity element inherits the attributes and model associations of FlowElement (see Table 8.44). Table 10.3 presents the additional attributes and model associations of the Activity element:

**Table 10.3 Activity attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>isForCompensation</strong>: boolean = false</td>
<td>A flag that identifies whether this Activity is intended for the purposes of compensation. If false, then this Activity executes as a result of normal execution flow. If true, this Activity is only activated when a Compensation Event is detected and initiated under Compensation Event visibility scope (see page 288 for more information on scopes).</td>
</tr>
<tr>
<td><strong>loopCharacteristics</strong>: LoopCharacteristics [0..1]</td>
<td>An Activity MAY be performed once or MAY be repeated. If repeated, the Activity MUST have loopCharacteristics that define the repetition criteria (if the isExecutable attribute of the Process is set to true).</td>
</tr>
<tr>
<td><strong>resources</strong>: ResourceRole [0..*]</td>
<td>Defines the resource that will perform or will be responsible for the Activity. The resource, e.g., a performer, can be specified in the form of a specific individual, a group, an organization role or position, or an organization.</td>
</tr>
<tr>
<td><strong>default</strong>: SequenceFlow [0..1]</td>
<td>The Sequence Flow that will receive a token when none of the conditionExpressions on other outgoing Sequence Flows evaluate to true. The default Sequence Flow should not have a conditionExpression. Any such Expression SHALL be ignored.</td>
</tr>
<tr>
<td><strong>properties</strong>: Property [0..*]</td>
<td>Modeler-defined properties MAY be added to an Activity. These properties are contained within the Activity.</td>
</tr>
<tr>
<td><strong>boundaryEventRefs</strong>: BoundaryEvent [0..*]</td>
<td>This references the Intermediate Events that are attached to the boundary of the Activity.</td>
</tr>
<tr>
<td><strong>dataInputAssociations</strong>: DataInputAssociation [0..*]</td>
<td>An optional reference to the DataInputAssociations. A DataInputAssociation defines how the DataInput of the Activity’s InputOutputSpecification will be populated.</td>
</tr>
<tr>
<td><strong>dataOutputAssociations</strong>: DataOutputAssociation [0..*]</td>
<td>An optional reference to the DataOutputAssociations.</td>
</tr>
</tbody>
</table>
In addition, an Activity instance has attributes whose values MAY be referenced by Expressions. These values are only available when the Activity is being executed.

Table 10.4 presents the instance attributes of the Activity element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>state: string = None</td>
<td>See Figure 13.2 (&quot;The Lifecycle of a BPMN Activity&quot;) in Section 13.2.2 for permissible values.</td>
</tr>
</tbody>
</table>

### Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 42 for the entire set of objects and how they MAY be sources or targets of Sequence Flows.

- An Activity MAY be a target for Sequence Flows; it can have multiple incoming Sequence Flows. Incoming Sequence Flows MAY be from an alternative path and/or parallel paths.
- If the Activity does not have an incoming Sequence Flow, then the Activity MUST be instantiated when the Process is instantiated.
- There are two (2) exceptions to this: Compensation Activities and Event Sub-Processes.

Note – If the Activity has multiple incoming Sequence Flows, then this is considered uncontrolled flow. This means that when a token arrives from one of the Paths, the Activity will be instantiated. It will not wait for the arrival of tokens from the other paths. If another token arrives from the same path or another path, then a separate instance of the Activity will be created. If the flow needs to be controlled, then the flow should converge on a Gateway that precedes the Activities (see 295 for more information on Gateways).

- An Activity MAY be a source for Sequence Flows; it can have multiple outgoing Sequence Flows. If there are multiple outgoing Sequence Flows, then this means that a separate parallel path is being created for each Sequence Flow (i.e., tokens will be generated for each outgoing Sequence Flow from the Activity).
- If the Activity does not have an outgoing Sequence Flow, then the Activity marks the end of one or more paths in the Process. When the Activity ends and there are no other parallel paths active, then the Process...
MUST be completed.

◆ There are two (2) exceptions to this: **Compensation Activities** and **Event Sub-Processes**.

**Message Flow Connections**

See Section “Message Flow Connection Rules” on page 43 for the entire set of objects and how they MAY be **sources or targets of Message Flows**.

**Note** – All **Message Flows** MUST connect two separate **Pools**. They MAY connect to the **Pool** boundary or to Flow Objects within the **Pool** boundary. They MUST NOT connect two objects within the same **Pool**.

◆ An **Activity** MAY be the target of a **Message Flow**; it can have zero (0) or more **incoming Message Flows**.

◆ An **Activity** MAY be a source of a **Message Flow**; it can have zero (0) or more **outgoing Message Flows**.

### 10.2.1 Resource Assignment

The following sections define how **Resources** can be defined for an **Activity**. Figure 10.7 displays the class diagram for the **BPMN** elements used for **Resource** assignment.

![Figure 10.7 - The class diagram for assigning Resources](image-url)

**Resource Role**

The **ResourceRole** element inherits the attributes and model associations of **BaseElement** (see Table 8.5). Table 10.5 presents the additional model associations of the **ResourceRole** element:
Expression Assignment

Resources can be assigned to an Activity using Expressions. These Expressions MUST return Resource entity related data types, like Users or Groups. Different Expressions can return multiple Resources. All of them are assigned to the respective subclass of the ResourceRole element, for example as potential owners. The semantics is defined by the subclass.

The ResourceAssignmentExpression element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.6 presents the additional model associations of the ResourceAssignmentExpression element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression: Expression</td>
<td>The element ResourceAssignmentExpression MUST contain an Expression which is used at runtime to assign resource(s) to a ResourceRole element.</td>
</tr>
</tbody>
</table>

Parameterized Resource Assignment

Resources support query parameters which are passed to the Resource query at runtime. Parameters MAY refer to Task instance data using Expressions. During Resource query execution, an infrastructure can decide which of the Parameters defined by the Resource are used. It MAY use zero (0) or more of the Parameters specified. It MAY also override certain Parameters with values defined during Resource deployment. The deployment mechanism for Tasks and Resources is out of scope for this specification. Resource queries are evaluated to determine the set of Resources, e.g. people, assigned to the Activity. Failed Resource queries are treated like Resource queries that return an empty result set. Resource queries return one Resource or a set of Resources.

The ResourceParameterBinding element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.7 presents the additional model associations of the ResourceParameterBinding element:
Table 10.7 – ResourceParameterBinding model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>parameterRef: ResourceParameter</td>
<td>Reference to the parameter defined by the Resource.</td>
</tr>
<tr>
<td>expression: Expression</td>
<td>The Expression that evaluates the value used to bind the ResourceParameter.</td>
</tr>
</tbody>
</table>

### 10.2.2 Performer

The Performer class defines the resource that will perform or will be responsible for an Activity. The performer can be specified in the form of a specific individual, a group, an organization role or position, or an organization.

The Performer element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to ResourceRole, but does not have any additional attributes or model associations.

### 10.2.3 Tasks

A Task is an atomic Activity within a Process flow. A Task is used when the work in the Process cannot be broken down to a finer level of detail. Generally, an end-user and/or applications are used to perform the Task when it is executed.

A Task object shares the same shape as the Sub-Process, which is a rectangle that has rounded corners (see Figure 10.8).

- A Task is a rounded corner rectangle that MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Task MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.
  - A boundary drawn with a thick line SHALL be reserved for Call Activity (Global Tasks) (see page 194).
  - A boundary drawn with a dotted line SHALL be reserved for Event Sub-Processes (see page 181) and thus are not allowed for Tasks.
  - A boundary drawn with a double line SHALL be reserved for Transaction Sub-Processes (see page 184) and thus are not allowed for Tasks.

Figure 10.8 - A Task object

BPMN specifies three types of markers for Task: a Loop marker or a Multi-Instance marker and a Compensation marker. A Task MAY have one or two of these markers (see Figure 10.9).
◆ The marker for a **Task** that is a standard *loop* MUST be a small line with an arrowhead that curls back upon itself. See page 196 for more information on *loop* **Activities**.

◆ The *loop* **Marker** MAY be used in combination with the *compensation* **marker**.

◆ The marker for a **Task** that is a *multi-instance* MUST be a set of three vertical lines. See page 198 for more information on *multi-instance** Activities**.

◆ If the *multi-instance instances* are set to be performed in sequence rather than parallel, then the marker will be rotated 90 degrees (see Figure 10.49, below).

◆ The *multi-instance* **marker** MAY be used in combination with the *compensation* **marker**.

◆ The marker for a **Task** that is used for *compensation* MUST be a pair of left facing triangles (like a tape player “rewind” button). See page 311 for more information on *compensation*.

◆ The **Compensation** **Marker** MAY be used in combination with the *loop* **marker** or the *multi-instance marker**.

All the markers that are present MUST be grouped and the whole group centered at the bottom of the shape.

![Figure 10.9 - Task markers](image)

Figure 10.10 displays the class diagram for the Task element.

![Figure 10.10 - The Task class diagram](image)

The **Task** inherits the attributes and model associations of **Activity** (see Table 10.3). There are no further attributes or model associations of the **Task**.
Types of Tasks

There are different types of Tasks identified within BPMN to separate the types of inherent behavior that Tasks might represent. The list of Task types MAY be extended along with any corresponding indicators. A Task which is not further specified is called Abstract Task (this was referred to as the None Task in BPMN 1.2). The notation of the Abstract Task is shown in Figure 10.8.

Service Task

A Service Task is a Task that uses some sort of service, which could be a Web service or an automated application.

A Service Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a graphical marker in the upper left corner of the shape that indicates that the Task is a Service Task (see Figure 10.11).

A Service Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a marker that distinguishes the shape from other Task types (as shown in Figure 10.11).

![Figure 10.11 - A Service Task Object](image)

The Service Task inherits the attributes and model associations of Activity (see Table 10.3). In addition the following constraints are introduced when the Service Task references an Operation: The Service Task has exactly one inputSet and at most one outputSet. It has a single Data Input with an ItemDefinition equivalent to the one defined by the Message referenced by the inMessageRef attribute of the associated Operation. If the Operation defines output Messages, the Service Task has a single Data Output that has an ItemDefinition equivalent to the one defined by the Message referenced by the outMessageRef attribute of the associated Operation.

The actual Participant whose service is used can be identified by connecting the Service Task to a Participant using a Message Flows within the definitional Collaboration of the Process – see Table 10.1.
The Service Task inherits the attributes and model associations of Activity (see Table 10.3). Table 10.8 presents additional the model associations of the Service Task:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>implementation: string</td>
<td>This attribute specifies the technology that will be used to send and receive the Messages. Valid values are &quot;##unspecified&quot; for leaving the implementation technology open, &quot;##WebService&quot; for the Web service technology or a URI identifying any other technology or coordination protocol. A Web service is the default technology.</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>This attribute specifies the operation that is invoked by the Service Task.</td>
</tr>
</tbody>
</table>

Send Task

A Send Task is a simple Task that is designed to send a Message to an external Participant (relative to the Process). Once the Message has been sent, the Task is completed.

The actual Participant which the Message is sent can be identified by connecting the Send Task to a Participant using a Message Flows within the definitional Collaboration of the Process – see Table 10.1.

A Send Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a filled envelope marker (the same marker as a throw Message Event) in the upper left corner of the shape that indicates that the Task is a Send Task.
A **Send Task** is a rounded corner rectangle that MUST be drawn with a single thin line and includes a filled envelope marker that distinguishes the shape from other **Task** types (as shown in Figure 10.13).

![Figure 10.13 - A Send Task Object](image)

The **Send Task** inherits the attributes and model associations of **Activity** (see Table 10.3). In addition the following constraints apply when the **Send Task** references a **Message**: The **Send Task** has at most one **inputSet** and one **Data Input**. If the **Data Input** is present, it MUST have an **ItemDefinition** equivalent to the one defined by the associated **Message**. At execution time, when the **Send Task** is executed, the data automatically moves from the **Data Input** on the **Send Task** into the **Message** to be sent. If the **Data Input** is not present, the **Message** will not be populated with data from the **Process**.

Table 10.9 presents the additional model associations of the **Send Task**:

---

Business Process Model and Notation, v2.0
Receive Task

A **Receive Task** is a simple **Task** that is designed to wait for a **Message** to arrive from an external **Participant** (relative to the **Process**). Once the **Message** has been received, the **Task** is completed.

The actual **Participant** from which the **Message** is received can be identified by connecting the **Receive Task** to a **Participant** using a **Message Flows** within the definitional **Collaboration** of the **Process** – see Table 10.1.

A **Receive Task** is often used to start a **Process**. In a sense, the **Process** is bootstrapped by the receipt of the **Message**. In order for the **Receive Task** to instantiate the **Process** its **instantiate** attribute MUST be set to **true** and it MUST NOT have any incoming **Sequence Flow**.

A **Receive Task** object shares the same shape as the **Task**, which is a rectangle that has rounded corners. However, there is an unfilled envelope marker (the same marker as a **catch Message Event**) in the upper left corner of the shape that indicates that the **Task** is a **Receive Task**.

A **Receive Task** is a rounded corner rectangle that MUST be drawn with a single thin line and includes an unfilled envelope marker that distinguishes the shape from other **Task** types (as shown in Figure 10.15). If the **instantiate** attribute is set to **true**, the envelope marker looks like a **Message Start Event** (as shown in Figure 10.16).

---

**Table 10.9 – Send Task model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>messageRef</strong>: Message [0..1]</td>
<td>A <strong>Message</strong> for the <strong>messageRef</strong> attribute MAY be entered. This indicates that the <strong>Message</strong> will be sent by the <strong>Task</strong>. The <strong>Message</strong> in this context is equivalent to an <em>out-only</em> message pattern (Web service). One or more corresponding outgoing <strong>Message Flows</strong> MAY be shown on the diagram. However, the display of the <strong>Message Flows</strong> is NOT REQUIRED. The <strong>Message</strong> is applied to all outgoing <strong>Message Flows</strong> and the <strong>Message</strong> will be sent down all outgoing <strong>Message Flows</strong> at the completion of a single <em>instance</em> of the <strong>Task</strong>.</td>
</tr>
<tr>
<td><strong>operationRef</strong>: Operation</td>
<td>This attribute specifies the operation that is invoked by the <strong>Send Task</strong>.</td>
</tr>
<tr>
<td><strong>implementation</strong>: string = ##webService</td>
<td>This attribute specifies the technology that will be used to send and receive the <strong>Messages</strong>. Valid values are &quot;##unspecified&quot; for leaving the implementation technology open, &quot;##WebService&quot; for the Web service technology or a URI identifying any other technology or coordination protocol. A Web service is the default technology.</td>
</tr>
</tbody>
</table>

---

**Figure 10.15 - A Receive Task Object**
The **Receive Task** inherits the attributes and model associations of **Activity** (see Table 10.3). In addition the following constraints apply when the **Receive Task** references a **Message**: The **Receive Task** has at most one **outputSet** and at most one **Data output**. If the **Data output** is present, it MUST have an **ItemDefinition** equivalent to the one defined by the associated **Message**. At execution time, when the **Receive Task** is executed, the data automatically moves from the **Message** to the **Data Output** on the **Receive Task**. If the **Data Output** is not present, the payload within the **Message** will not flow out of the **Receive Task** and into the **Process**.

Table 10.10 presents the additional attributes and model associations of the **Receive Task**: 
Table 10.10 – Receive Task attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageRef: Message [0..1]</td>
<td>A Message for the messageRef attribute MAY be entered. This indicates that the Message will be received by the Task. The Message in this context is equivalent to an in-only message pattern (Web service). One (1) or more corresponding incoming Message Flows MAY be shown on the diagram. However, the display of the Message Flows is NOT REQUIRED. The Message is applied to all incoming Message Flows, but can arrive for only one (1) of the incoming Message Flows for a single instance of the Task.</td>
</tr>
<tr>
<td>instantiate: boolean = false</td>
<td>Receive Tasks can be defined as the instantiation mechanism for the Process with the instantiate attribute. This attribute MAY be set to true if the Task is the first Activity (i.e., there are no incoming Sequence Flows). Multiple Tasks MAY have this attribute set to true.</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>This attribute specifies the operation through which the Receive Task receives the Message.</td>
</tr>
<tr>
<td>implementation: string = ##webService</td>
<td>This attribute specifies the technology that will be used to send and receive the Messages. Valid values are &quot;##unspecified&quot; for leaving the implementation technology open, &quot;##WebService&quot; for the Web service technology or a URI identifying any other technology or coordination protocol A Web service is the default technology.</td>
</tr>
</tbody>
</table>

User Task

A User Task is a typical “workflow” Task where a human performer performs the Task with the assistance of a software application and is scheduled through a task list manager of some sort.

A User Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a human figure marker that distinguishes the shape from other Task types (as shown in Figure 10.17).

Figure 10.17 - A User Task Object

See “User Task” on page 167 within the larger section of “Human Interactions” for the details of User Tasks.
**Manual Task**

A **Manual Task** is a **Task** that is expected to be performed without the aid of any business process execution engine or any application. An example of this could be a telephone technician installing a telephone at a customer location.

A **Manual Task** is a rounded corner rectangle that MUST be drawn with a single thin line and includes a hand figure marker that distinguishes the shape from other **Task** types (as shown in Figure 10.17).

![Figure 10.18 - A Manual Task Object](image)

See “Manual Task” on page 170 within the larger section of “Human Interactions” for the details of **Manual Tasks**.

**Business Rule**

A **Business Rule Task** provides a mechanism for the **Process** to provide input to a Business Rules Engine and to get the output of calculations that the Business Rules Engine might provide. The **InputOutputSpecification** of the **Task** (see page 218) will allow the **Process** to send data to and receive data from the Business Rules Engine.

A **Business Rule Task** object shares the same shape as the **Task**, which is a rectangle that has rounded corners. However, there is a graphical marker in the upper left corner of the shape that indicates that the **Task** is a **Business Rule Task** (see Figure 10.11).

A **Business Rule Task** is a rounded corner rectangle that MUST be drawn with a single thin line and includes a marker that distinguishes the shape from other **Task** types (as shown in Figure 10.19).

![Figure 10.19 - A Business Rule Task Object](image)

The **Business Rule Task** inherits the attributes and model associations of **Activity** (see Table 10.3). Table 10.11 presents the additional attributes of the **Business Rule Task**:
A Script Task is executed by a business process engine. The modeler or implementer defines a script in a language that the engine can interpret. When the Task is ready to start, the engine will execute the script. When the script is completed, the Task will also be completed.

A Script Task object shares the same shape as the Task, which is a rectangle that has rounded corners. However, there is a graphical marker in the upper left corner of the shape that indicates that the Task is a Script Task (see Figure 10.11).

A Script Task is a rounded corner rectangle that MUST be drawn with a single thin line and includes a marker that distinguishes the shape from other Task types (as shown in Figure 10.20).

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>implementation: string = ##unspecified</td>
<td>This attribute specifies the technology that will be used to implement the Business Rule Task. Valid values are &quot;##unspecified&quot; for leaving the implementation technology open, &quot;##WebService&quot; for the Web service technology or a URI identifying any other technology or coordination protocol. The default technology for this task is unspecified.</td>
</tr>
</tbody>
</table>

Figure 10.20 - A Script Task Object

The Script Task inherits the attributes and model associations of Activity (see Table 10.3). Table 10.12 presents the additional attributes of the Script Task:
10.2.4 Human Interactions

Tasks with Human involvement

In many business workflows, human involvement is needed to complete certain Tasks specified in the workflow model. BPMN specifies two different types of Tasks with human involvement, the Manual Task and the User Task.

A User Task is executed by and managed by a business process runtime. Attributes concerning the human involvement, like people assignments and UI rendering can be specified in great detail. A Manual Task is neither executed by nor managed by a business process runtime.

Notation

Both, the Manual Task and User Task share the same shape, which is a rectangle that has rounded corners. Manual Tasks and User Tasks have a Icons to indicate the human involvement is REQUIRED to complete the Task (see Figure 10.15 and Figure 10.17, above).

Manual Task

A Manual Task is a Task that is not managed by any business process engine. It can be considered as an unmanaged Task, unmanaged in the sense of that the business process engine doesn’t track the start and completion of such a Task. An example of this could be a paper based instruction for a telephone technician to install a telephone at a customer location.

Table 10.12 – Script Task attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>scriptFormat: string [0..1]</td>
<td>Defines the format of the script. This attribute value MUST be specified with a mime-type format. And it MUST be specified if a script is provided.</td>
</tr>
<tr>
<td>script: string [0..1]</td>
<td>The modeler MAY include a script that can be run when the Task is performed. If a script is not included, then the Task will act as the equivalent of an Abstract Task.</td>
</tr>
</tbody>
</table>

Figure 10.21 - Manual Task class diagram
The **User Task** inherits the attributes and model associations of **Activity** (see Table 10.3), but does not have any additional attributes or model associations.

**User Task**

A **User Task** is a typical “workflow” **Task** where a human performer performs the **Task** with the assistance of a software application. The lifecycle of the **Task** is managed by a software component (called task manager) and is typically executed in the context of a **Process**.

![User Task class diagram](image)

**Figure 10.22 - User Task class diagram**

The **User Task** can be implemented using different technologies, specified by the implementation attribute. Besides the Web service technology, any technology can be used. A **User Task** for instance can be implemented using WS-HumanTask by setting the implementation attribute to "http://docs.oasis-open.org/ns/bpel4people/ws-humantask/protocol/200803."

The **User Task** inherits the attributes and model associations of **Activity** (see Table 10.3). Table 10.13 presents the additional attributes and model associations of the **User Task**. If implementations extend these attributes (e.g., to introduce subjects or descriptions with presentation parameters), they SHOULD use attributes defined by the OASIS WS-HumanTask specification.
BPMN User Tasks need to be rendered on user interfaces like forms clients, portlets, etc. The Rendering element provides an extensible mechanism for specifying UI renderings for User Tasks (Task UI). The element is optional. One or more rendering methods can be provided in a Task definition. A User Task can be deployed on any compliant implementation, irrespective of the fact whether the implementation supports specified rendering methods or not. The Rendering element is the extension point for renderings. Things like language considerations are opaque for the Rendering element because the rendering applications typically provide Multilanguage support. Where this is not the case, providers of certain rendering types can decide to extend the rendering type in order to provide language information for a given rendering. The content of the rendering element is not defined by this specification.

### Human Performers

People can be assigned to Activities in various roles (called “generic human roles” in WS-HumanTask). BPMN 1.2 traditionally only has the Performer role. In addition to supporting the Performer role, BPMN 2.0 defines a specific HumanPerformer element allowing specifying more specific human roles as specialization of HumanPerformer, such as PotentialOwner.
The `HumanPerformer` element inherits the attributes and model associations of `ResourceRole` (see Table 10.5), through its relationship to `Performer`, but does not have any additional attributes or model associations.

**Potential Owners**

Potential owners of a **User Task** are persons who can claim and work on it. A potential owner becomes the actual owner of a **Task**, usually by explicitly claiming it.

**XML Schema for Human Interactions**

**Table 10.15 – ManualTask XML schema**

```xml
<xsd:element name="manualTask" type="tManualTask" substitutionGroup="flowElement"/>
<xsd:complexType name="tManualTask">
    <xsd:complexContent>

                <xsd:enumeration value="##WebService"/>
            </xsd:restriction>
        </xsd:simpleType>
    </xsd:union>
</xsd:simpleType>
```

Table 10.17 – HumanPerformer XML schema

```xml
<xsd:element name="humanPerformer" type="tHumanPerformer" substitutionGroup="performer"/>
<xsd:complexType name="tHumanPerformer">
    <xsd:complexContent>
        <xsd:extension base="tPerformer">
            <xsd:sequence>
                <xsd:element ref="peopleAssignment" minOccurs="1" maxOccurs="1"/>
            </xsd:sequence>
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```
Examples

Consider the following sample procurement Process from the Buyer perspective (see Figure 10.24).

The Process comprises of two User Tasks

- **Approve Order**: After the quotation handling, the order needs to be approved by some regional manager to continue with the order and shipment handling.

- **Review Order**: Once the order has been shipped to the Buyer, the order and shipment documents will be reviewed again by someone.

The details of the Resource and resource assignments are not shown in the BPMN above. See below XML sample of the “Buyer” Process for the Resource usage and resource assignments for potential owners.

Table 10.19 – XML serialization of Buyer process

```xml
<?xml version="1.0" encoding="UTF-8"?>

10.2.5 Sub-Processes

A **Sub-Process** is an **Activity** whose internal details have been modeled using **Activities**, **Gateways**, **Events**, and **Sequence Flows**. A **Sub-Process** is a graphical object within a **Process**, but it also can be “opened up” to show a lower-level **Process**. **Sub-Processes** define a contextual **scope** that can be used for attribute visibility, transactional **scope**, for the handling of **exceptions** (see page 283 for more details), of **Events**, or for **compensation** (see page 311 for more details).

There are different types of **Sub-Processes**, which will be described in the next five (5) sections.

**Embedded Sub-Process (Sub-Process)**

A **Sub-Process** object shares the same shape as the **Task** object, which is a rounded rectangle.

- A **Sub-Process** is a rounded corner rectangle that MUST be drawn with a single thin line.
  - The use of text, color, size, and lines for a **Sub-Process** MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41 with the exception that:
    - A boundary drawn with a thick line SHALL be reserved for **Call Activity (Sub-Processes)** (see page 189).
    - A boundary drawn with a dotted line SHALL be reserved for **Event Sub-Processes** (see page 181).
    - A boundary drawn with a double line SHALL be reserved for **Transaction Sub-Processes** (see page 184).

The **Sub-Process** can be in a collapsed view that hides its details (see Figure 10.25) or a **Sub-Process** can be in an expanded view that shows its details within the view of the **Process** in which it is contained (see Figure 10.26). In the collapsed form, the **Sub-Process** object uses a marker to distinguish it as a **Sub-Process**, rather than a **Task**.

- The **Sub-Process** marker MUST be a small square with a plus sign (+) inside. The square MUST be positioned at the bottom center of the shape.
They are used to create a context for exception handling that applies to a group of Activities (see page 283 for more details). Compensations can be handled similarly (see page 311 for more details).

Expanded Sub-Processes can be used as a mechanism for showing a group of parallel Activities in a less-cluttered, more compact way. In Figure 10.27, Activities “C” and “D” are enclosed in an unlabeled expanded Sub-Process. These two Activities will be performed in parallel. Notice that the expanded Sub-Process does not include a Start Event or an End Event and the Sequence Flows to/from these Events. This usage of expanded Sub-Processes for “parallel boxes” is the motivation for having Start and End Events being optional objects.
BPMN specifies five (5) types of standard markers for Sub-Processes. The (Collapsed) Sub-Process marker, seen in Figure 10.24, can be combined with four (4) other markers: a loop marker or a multi-instance marker, a Compensation marker, and an Ad-Hoc marker. A collapsed Sub-Process MAY have one to three of these other markers, in all combinations except that loop and multi-instance cannot be shown at the same time (see Figure 10.28).

- The marker for a Sub-Process that loops MUST be a small line with an arrowhead that curls back upon itself.
- The loop marker MAY be used in combination with any of the other markers except the multi-instance marker.
- The marker for a Sub-Process that has multiple instances MUST be a set of three vertical lines in parallel.
- The multi-instance marker MAY be used in combination with any of the other markers except the loop marker.
- The marker for an ad-hoc Sub-Process MUST be a “tilde” symbol.
- The ad-hoc marker MAY be used in combination with any of the other markers.
- The marker for a Sub-Process that is used for compensation MUST be a pair of left facing triangles (like a tape player “rewind” button).
- The Compensation marker MAY be used in combination with any of the other markers.
- All the markers that are present MUST be grouped and the whole group centered at the bottom of the Sub-Process.

The Sub-Process now corresponds to the Embedded Sub-Process of BPMN 1.2. The Reusable Sub-Process of BPMN 1.2 corresponds to the Call Activity (calling a Process - see page 189).
Figure 10.28 shows the class diagram related to Sub-Processes.

Figure 10.29 - The Sub-Process class diagram

The Sub-Process element inherits the attributes and model associations of Activity (see Table 10.3) and of FlowElementContainer (see Table 8.45). Table 10.3 presents the additional attributes of the Sub-Process element:

Table 10.20 – Sub-Process attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
</table>
| triggeredByEvent: boolean = false | A flag that identifies whether this Sub-Process is an Event Sub-Process.  
  - If false, then this Sub-Process is a normal Sub-Process.  
  - If true, then this Sub-Process is an Event Sub-Process and is subject to additional constraints (see page 181). |
| artifacts: Artifact [0..*] | This attribute provides the list of Artifacts that are contained within the Sub-Process. |

Reusable Sub-Process (Call Activity)

The reusable Sub-Process of BPMN 1.2 corresponds to the Call Activity that calls a pre-defined Process. See details of a Call Activity on page 189.

Event Sub-Process

An Event Sub-Process is a specialized Sub-Process that is used within a Process (or Sub-Process). A Sub-Process is defined as an Event Sub-Process when its triggeredByEvent attribute is set to true.
An Event Sub-Process is not part of the normal flow of its parent Process—there are no incoming or outgoing Sequence Flows.

- An Event Sub-Process MUST NOT have any incoming or outgoing Sequence Flows.

An Event Sub-Process MAY or MAY NOT occur while the parent Process is active, but it is possible that it will occur many times. Unlike a standard Sub-Process, which uses the flow of the parent Process as a trigger, an Event Sub-Process has a Start Event with a trigger. Each time the Start Event is triggered while the parent Process is active, then the Event Sub-Process will start.

- The Start Event of an Event Sub-Process MUST have a defined trigger.
- The Start Event trigger (EventDefinition) MUST be from the following types: Message, Error, Escalation, Compensation, Conditional, Signal, and Multiple (see page 268 for more details).
- An Event Sub-Process MUST have one and only one Start Event.

An Event Sub-Process object shares the same basic shape as the Sub-Process object, which is a rounded rectangle.

- An Event Sub-Process is a rounded corner rectangle that MUST be drawn with a single thin dotted line (see Figure 10.30 and Figure 10.31).
- The use of text, color, size, and lines for an Event Sub-Process MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41 with the exception that:
- If the Event Sub-Process is collapsed, then its Start Event will be used as a marker in the upper left corner of the shape (see Figure 10.30).

![Figure 10.30 - An Event Sub-Process object (Collapsed)](image1)

![Figure 10.31 - An Event Sub-Process object (expanded)](image2)
There are two (2) possible consequences to the parent Process when an Event Sub-Process is triggered: 1) the parent Process can be interrupted, and 2) the parent Process can continue its work (not interrupted). This is determined by the type of Start Event that is used. See page 249 for the list of interrupting and non-interrupting Event Sub-Process Start Events.

Figure 10.32 provides an example of a Sub-Process that includes three (3) Event Sub-Processes. The first Event Sub-Process is triggered by a Message, does not interrupt the Sub-Process, and can occur multiple times. The second Event Sub-Process is used for compensation and will only occur after the Sub-Process has completed. The third Event Sub-Process handles errors that occur while the Sub-Process is active and will stop (interrupt) the Sub-Process if triggered.

Figure 10.32 - An example that includes Event Sub-Processes
A Transaction is a specialized type of Sub-Process which will have a special behavior that is controlled through a transaction protocol (such as WS-Transaction). The boundary of the Sub-Process will be double-lined to indicate that it is a Transaction (see Figure 10.33).

- A Transaction Sub-Process is a rounded corner rectangle that MUST be drawn with a double thin line.
- The use of text, color, size, and lines for a transaction Sub-Process MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

Figure 10.33 - A Transaction Sub-Process
Figure 10.34 - A Collapsed Transaction Sub-Process

The **Transaction Sub-Process** element inherits the attributes and model associations of **Activities** (see Table 10.3) through its relationship to **Sub-Process**. Table 10.21 presents the additional attributes and model associations of the **Transaction Sub-Process**:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>method: TransactionMethod</td>
<td>The method is an attribute that defines the Transaction method used to commit or cancel a Transaction. For executable Processes, it SHOULD be set to a technology specific URI, e.g., <a href="http://schemas.xmlsoap.org/ws/2004/10/wsat">http://schemas.xmlsoap.org/ws/2004/10/wsat</a> for WS-AtomicTransaction, or <a href="http://docs.oasis-open.org/ws-tx/wsba/2006/06/AtomicOutcome">http://docs.oasis-open.org/ws-tx/wsba/2006/06/AtomicOutcome</a> for WS-BusinessActivity. For compatibility with BPMN 1.1, it can also be set to &quot;##compensate&quot;, &quot;##store&quot;, or &quot;##image&quot;.</td>
</tr>
</tbody>
</table>

There are three basic outcomes of a **Transaction**:

1. **Successful completion**: this will be shown as a normal **Sequence Flow** that leaves the **Transaction Sub-Process**.

2. **Failed completion (Cancel)**: When a **Transaction** is cancelled, the **Activities** inside the **Transaction** will be subjected to the cancellation actions, which could include rolling back the **Process** and **compensation** (see page 311 for more information on compensation) for specific **Activities**. Note that other mechanisms for interrupting a **Transaction Sub-Process** will not cause compensation (e.g., Error, Timer, and anything for a non-Transaction Activity). A **Cancel Intermediate Event**, attached to the boundary of the **Activity**, will direct the flow after the
Transaction has been rolled back and all compensation has been completed. The Cancel Intermediate Event can only be used when attached to the boundary of a Transaction Sub-Process. It cannot be used in any normal flow and cannot be attached to a non-Transaction Sub-Process. There are two mechanisms that can signal the cancellation of a Transaction:

- A Cancel End Event is reached within the Transaction Sub-Process. A Cancel End Event can only be used within a transaction Sub-Process.
- A cancel Message can be received via the transaction protocol that is supporting the execution of the Transaction Sub-Process.

3. Hazard: This means that something went terribly wrong and that a normal success or cancel is not possible. Error Intermediate Events are used to show Hazards. When a Hazard happens, the Activity is interrupted (without compensation) and the flow will continue from the Error Intermediate Event.

The behavior at the end of a successful Transaction Sub-Process is slightly different than that of a normal Sub-Process. When each path of the Transaction Sub-Process reaches a non-Cancel End Event(s), the flow does not immediately move back up to the higher-level parent Process, as does a normal Sub-Process. First, the transaction protocol needs to verify that all the Participants have successfully completed their end of the Transaction. Most of the time this will be true and the flow will then move up to the higher-level Process. But it is possible that one of the Participants can end up with a problem that causes a Cancel or a Hazard. In this case, the flow will then move to the appropriate Intermediate Event, even though it had apparently finished successfully.

Ad-Hoc Sub-Process

An Ad-Hoc Sub-Process is a specialized type of Sub-Process that is a group of Activities that have no REQUIRED sequence relationships. A set of Activities can be defined for the Process, but the sequence and number of performances for the Activities is determined by the performers of the Activities.

A Sub-Process is marked as being ad-hoc with a “tilde” symbol placed at the bottom center of the Sub-Process shape (see Figure 10.35 and Figure 10.36). 

- The marker for an Ad-Hoc Sub-Process MUST be a “tilde” symbol.
- The Ad-Hoc Marker MAY be used in combination with any of the other markers.

Figure 10.35 - A collapsed Ad-Hoc Sub-Process
The Ad-Hoc Sub-Process element inherits the attributes and model associations of Activities (see Table 10.3) through its relationship to Sub-Process. Table 10.22 presents the additional model associations of the Ad-Hoc Sub-Process:

### Table 10.22 – Ad-hoc Sub-Process model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>completionCondition: Expression</td>
<td>This Expression defines the conditions when the Process will end. When the Expression is evaluated to true, the Process will be terminated.</td>
</tr>
<tr>
<td>ordering: AdHocOrdering = Parallel { Parallel</td>
<td>Sequential }</td>
</tr>
<tr>
<td>cancelRemaining-Instances: boolean = true</td>
<td>This attribute is used only if ordering is parallel. It determines whether running instances are cancelled when the completionCondition becomes true.</td>
</tr>
</tbody>
</table>

Activities within the Process are generally disconnected from each other. During execution of the Process, any one or more of the Activities MAY be active and they MAY be performed multiple times. The performers determine when Activities will start, what the next Activity will be, and so on.

Examples of the types of Processes that are Ad-Hoc include computer code development (at a low level), sales support, and writing a book chapter. If we look at the details of writing a book chapter, we could see that the Activities within this Process include: researching the topic, writing text, editing text, generating graphics, including graphics in the text, organizing references, etc. (see Figure 10.37). There MAY be some dependencies between Tasks in this Process, such as writing text before editing text, but there is not necessarily any correlation between an instance of writing text to an instance of editing text. Editing can occur infrequently and based on the text of many instances of the writing text Task.
Although there is no explicit Process structure, some sequence and data dependencies can be added to the details of the Process. For example, we can extend the book chapter Ad-Hoc Sub-Process shown above and add Data Objects, Data Associations, and even Sequence Flows (Figure 10.38).

Ad-Hoc Sub-Processes restrict the use of BPMN elements that would normally be used in Sub-Processes.

- The list of BPMN elements that MUST be used in an Ad-Hoc Sub-Process: Activity.
- The list of BPMN elements that MAY be used in an Ad-Hoc Sub-Process: Data Object, Sequence Flow, Association, Data Association, Group, Message Flow (as a source or target), Gateway, and Intermediate Event.
- The list of BPMN elements that MUST NOT be used in an Ad-Hoc Sub-Process: Start Event, End Event, Conversations (graphically), Conversation Links (graphically), and Choreography Activities.
The **Data Objects** as inputs into the **Tasks** act as an additional constraint for the performance of those **Tasks**. The **performers** still determine when the **Tasks** will be performed, but they are now constrained in that they cannot start the **Task** without the appropriate input. The addition of **Sequence Flows** between the **Tasks** (e.g., between “Generate Graphics” and “Include Graphics in Text”) creates a dependency where the performance of the first **Task** MUST be followed by a performance of the second **Task**. This does not mean that the second **Task** is to be performed immediately, but there MUST be a performance of the second **Task** after the performance of the first **Task**.

It is a challenge for a BPM engine to monitor the status of **Ad-Hoc Sub-Processes**, usually these kind of **Processes** are handled through groupware applications (such as e-mail), but **BPMN** allows modeling of **Processes** that are not necessarily executable, although there are some process engines that can follow an **Ad-Hoc Sub-Process**. Given this, at some point the **Ad-Hoc Sub-Process** will have complete and this can be determined by evaluating a completionCondition that evaluates **Process** attributes that will have been updated by an **Activity** in the **Process**.

### 10.2.6 Call Activity

A **Call Activity** identifies a point in the **Process** where a global **Process** or a Global **Task** is used. The **Call Activity** acts as a ‘wrapper’ for the invocation of a global **Process** or Global **Task** within the execution. The activation of a call **Activity** results in the transfer of control to the called global **Process** or Global **Task**.
The BPMN 2.0 Call Activity corresponds to the Reusable Sub-Process of BPMN 1.2. A BPMN 2.0 Sub-Process corresponds to the Embedded Sub-Process of BPMN 1.2 (see the previous section).

A Call Activity object shares the same shape as the Task and Sub-Process, which is a rectangle that has rounded corners. However, the target of what the Activity calls will determine the details of its shape.

- If the Call Activity calls a Global Task, then the shape will be the same as a Task, but the boundary of the shape will MUST have a thick line (see Figure 10.39).
- The Call Activity MUST display the marker of the type of Global Task (e.g., the Call Activity would display the User Task marker if calling a Global User Task).

- If the Call Activity calls a Process, then there are two (2) options:
  - The details of the called Process can be hidden and the shape of the Call Activity will be the same as a collapsed Sub-Process, but the boundary of the shape MUST have a thick line (see Figure 10.40).
  - If the details of the called Process are available, then the shape of the Call Activity will be the same as a expanded Sub-Process, but the boundary of the shape MUST have a thick line (see Figure 10.41).
When a Process with a definition Collaboration, calls a Process that also has a definition Collaboration, the Participants of the two (2) Collaborations can be matched to each other using ParticipantAssociations of the Collaboration of the calling Process.

A Call Activity MUST fulfill the data requirements, as well as return the data produced by the CallableElement being invoked (see Figure 10.41). This means that the elements contained in the Call Activity’s InputOutputSpecification MUST exactly match the elements contained in the referenced CallableElement. This includes DataInputs, DataOutputs, InputSets, and OutputSets.
A **Call Activity** can override properties and attributes of the element being called, potentially changing the behavior of the called element based on the calling context. For example, when the **Call Activity** defines one or more **ResourceRole** elements, the elements defined by the **CallableElement** are ignored and the elements defined in the **Call Activity** are used instead. Also, **Events** that are propagated along the hierarchy (errors and escalations) are propagated from the called element to the **Call Activity** (and can be handled on its boundary).

The **Call Activity** inherits the attributes and model associations of **Activity** (see Table 10.3). Table 10.23 presents the additional model associations of the **Call Activity**:

**Table 10.23 – CallActivity model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>calledElement: CallableElement [0..1]</td>
<td>The element to be called, which will be either a <strong>Process</strong> or a <strong>GlobalTask</strong>. Other <strong>CallableElements</strong>, such as <strong>Choreography</strong>, <strong>GlobalChoreographyTask</strong>, <strong>Conversation</strong>, and <strong>GlobalCommunication</strong> MUST NOT be called by the <strong>Call Conversation</strong> element.</td>
</tr>
</tbody>
</table>
Callable Element

CallableElement is the abstract super class of all Activities that have been defined outside of a Process or Choreography but which can be called (or reused), by a Call Activity, from within a Process or Choreography. It MAY reference Interfaces that define the service operations that it provides. The BPMN elements that can be called by Call Activities (i.e., are CallableElements) are: Process and GlobalTask (see Figure 10.43).

CallableElements are RootElements, which can be imported and used in other Definitions. When CallableElements (e.g., Process) are defined, they are contained within Definitions.

---

**Figure 10.43 - CallableElement class diagram**

The CallableElement inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to RootElement. Table 10.24 presents the additional attributes and model associations of the CallableElement:
When a CallableElement is exposed as a Service, it has to define one or more InputOutputBinding elements. An InputOutputBinding element binds one Input and one Output of the InputOutputSpecification to an Operation of a Service Interface. Table 10.25 presents the additional model associations of the InputOutputBinding:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>The descriptive name of the element.</td>
</tr>
<tr>
<td>supportedInterfaceRefs: Interface [0..*]</td>
<td>The Interfaces describing the external behavior provided by this element.</td>
</tr>
<tr>
<td>ioBinding: InputOutputBinding [0..*]</td>
<td>The InputOutputBinding defines a combination of one InputSet and one OutputSet in order to bind this to an operation defined in an interface.</td>
</tr>
<tr>
<td>inputDataRef: DataInput</td>
<td>A reference to one specific DataInput defined as part of the InputOutputSpecification of the Activity.</td>
</tr>
<tr>
<td>outputDataRef: DataOutput</td>
<td>A reference to one specific DataOutput defined as part of the InputOutputSpecification of the Activity.</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>A reference to one specific Operation defined as part of the Interface of the Activity.</td>
</tr>
</tbody>
</table>

10.2.7 Global Task

A Global Task is a reusable, atomic Task definition that can be called from within any Process by a Call Activity.
The `GlobalTask` inherits the attributes and model associations of `CallableElement` (see Table 10.24). Table 10.26 presents the additional model associations of the `GlobalTask`:

### Table 10.26 – Global Task model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>resources: ResourceRole [0..*]</td>
<td>Defines the resource that will perform or will be responsible for the GlobalTask. In the case where the Call Activity that references this GlobalTask defines its own resources, they will override the ones defined here.</td>
</tr>
</tbody>
</table>

### Types of Global Task

There are different types of Tasks identified within BPMN to separate the types of inherent behavior that Tasks might represent. The types of Global Tasks are only a subset of standard Tasks types. Only `GlobalUserTask`, `GlobalManualTask`, `GlobalScriptTask` and `GlobalBusinessRuleTask` are defined in BPMN. For the sake of efficiency in this specification, the list of Task types is presented once on page 160. The behavior, attributes, and model associations defined in that section also apply to the corresponding types of Global Tasks.
10.2.8 Loop Characteristics

Activities MAY be repeated sequentially, essentially behaving like a loop. The presence of LoopCharacteristics signifies that the Activity has looping behavior. LoopCharacteristics is an abstract class. Concrete subclasses define specific kinds of looping behavior.

The LoopCharacteristics inherits the attributes and model associations of BaseElement (see Table 8.5). There are no further attributes or model associations of the LoopCharacteristics.

However, each Loop Activity instance has attributes whose values MAY be referenced by Expressions. These values are only available when the Loop Activity is being executed.

Figure 10.45 displays the class diagram for an Activity’s loop characteristics, including the details of both the standard loop and a multi-instance.

![LoopCharacteristics class diagram](image)

The LoopCharacteristics element inherits the attributes and model associations of BaseElement (see Table 8.5), but does not have any further attributes or model associations. However, a Loop Activity does have additional instance attributes as shown in Table 10.27.
The StandardLoopCharacteristics class defines looping behavior based on a boolean condition. The Activity will loop as long as the boolean condition is true. The condition is evaluated for every loop iteration, and MAY be evaluated at the beginning or at the end of the iteration. In addition, a numeric cap can be optionally specified. The number of iterations MAY NOT exceed this cap.

- The marker for a Task or a Sub-Process that is a standard loop MUST be a small line with an arrowhead that curls back upon itself (see Figure 10.46 and Figure 10.47).
- The loop Marker MAY be used in combination with the Compensation Marker.

---

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>loopCounter:</td>
<td>The LoopCounter attribute is used at runtime to count the number of loops and is automatically updated by the process engine.</td>
</tr>
</tbody>
</table>

---

Standard Loop Characteristics

The StandardLoopCharacteristics class defines looping behavior based on a boolean condition. The Activity will loop as long as the boolean condition is true. The condition is evaluated for every loop iteration, and MAY be evaluated at the beginning or at the end of the iteration. In addition, a numeric cap can be optionally specified. The number of iterations MAY NOT exceed this cap.

- The marker for a Task or a Sub-Process that is a standard loop MUST be a small line with an arrowhead that curls back upon itself (see Figure 10.46 and Figure 10.47).
- The loop Marker MAY be used in combination with the Compensation Marker.
Multi-Instance Characteristics

The MultiInstanceLoopCharacteristics class allows for creation of a desired number of Activity instances. The instances MAY execute in parallel or MAY be sequential. Either an Expression is used to specify or calculate the desired number of instances or a data driven setup can be used. In that case a data input can be specified, which is able to handle a collection of data. The number of items in the collection determines the number of Activity instances. This data input can be produced by an input Data Association. The modeler can also configure this loop to control the tokens produced.

- The marker for a Task or Sub-Process that is a multi-instance MUST be a set of three vertical lines.
- If the multi-instance instances are set to be performed in parallel rather than sequential (the isSequential attribute set to false), then the lines of the marker will vertical (see Figure 10.48).
- If the multi-instance instances are set to be performed in sequence rather than parallel (the isSequential attribute set to true), then the marker will be horizontal (see Figure 10.49).
- The Multi-Instance marker MAY be used in combination with the Compensation marker.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>testBefore: boolean = false</td>
<td>Flag that controls whether the loop condition is evaluated at the beginning (testBefore = true) or at the end (testBefore = false) of the loop iteration.</td>
</tr>
<tr>
<td>loopMaximum: integer [0..1]</td>
<td>Serves as a cap on the number of iterations.</td>
</tr>
<tr>
<td>loopCondition: Expression [0..1]</td>
<td>A boolean Expression that controls the loop. The Activity will only loop as long as this condition is true. The looping behavior MAY be underspecified, meaning that the modeler can simply document the condition, in which case the loop cannot be formally executed.</td>
</tr>
</tbody>
</table>

Table 10.28 – StandardLoopCharacteristics attributes and model associations

Figure 10.48 - Activity Multi-Instance marker for parallel instances

Figure 10.49 - Activity Multi-Instance marker for sequential instances
The MultiInstanceLoopCharacteristics element inherits the attributes and model associations of BaseElement (see Table 8.5), through its relationship to LoopCharacteristics. Table 10.29 presents the additional attributes and model associations for the MultiInstanceLoopCharacteristics element.

### Table 10.29 - MultiInstanceLoopCharacteristics attributes and model associations

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>inputDataItem</strong></td>
<td>A Data Input, representing for every Activity instance the single item of the collection stored in the loopDataInput. This Data Input can be the source of DataInputAssociation to a data input of the Activity’s InputOutputSpecification. The type of this Data Input MUST the scalar of the type defined for the loopDataInput.</td>
</tr>
</tbody>
</table>
Table 10.29 - MultiInstanceLoopCharacteristics attributes and model associations

<table>
<thead>
<tr>
<th>attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>outputDataItem</strong>: DataOutput [0..1]</td>
<td>A Data Output, representing for every Activity instance the single item of the collection stored in the loopDataOutput. This Data Output can be the target of DataOutputAssociation to a data output of the Activity's InputOutputSpecification. The type of this Data Output MUST the scalar of the type defined for the loopDataOutput.</td>
</tr>
</tbody>
</table>
| **behavior**: MultiInstanceBehavior = all { None | One | All | Complex } | The attribute behavior acts as a shortcut for specifying when events SHALL be thrown from an Activity instance that is about to complete. It can assume values of None, One, All, and Complex, resulting in the following behavior:  
  - **None**: the EventDefinition which is associated through the noneEvent association will be thrown for each instance completing;  
  - **One**: the EventDefinition referenced through the oneEvent association will be thrown upon the first instance completing;  
  - **All**: no Event is ever thrown; a token is produced after completion of all instances  
  - **Complex**: the complexBehaviorDefinitions are consulted to determine if and which Events to throw.  
  For the behaviors of none and one, a default SignalEventDefinition will be thrown which automatically carries the current runtime attributes of the MI Activity. Any thrown Events can be caught by boundary Events on the Multi-Instance Activity. |
| **complexBehaviorDefinition**: ComplexBehaviorDefinition [0..*] | Controls when and which Events are thrown in case behavior is set to complex. |
| **completionCondition**: Expression [0..1] | This attribute defines a boolean Expression that when evaluated to true, cancels the remaining Activity instances and produces a token. |
| **oneBehaviorEventRef**: EventDefinition [0..1] | The EventDefinition which is thrown when behavior is set to one and the first internal Activity instance has completed. |
| **noneBehaviorEventRef**: EventDefinition [0..1] | The EventDefinition which is thrown when the behavior is set to none and an internal Activity instance has completed. |

Table 10.30 lists all instance attributes available at runtime. For each instance of the Multi-Instance Activity (outer instance), there exist a number of generated (inner) instances of the Activity at runtime.
Complex Behavior Definition

This element controls when and which Events are thrown in case behavior of the Multi-Instance Activity is set to complex.

The ComplexBehaviorDefinition element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.31 presents the additional attributes and model associations for the ComplexBehaviorDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>loopCounter: integer</td>
<td>This attribute is provided for each generated (inner) instance of the Activity. It contains the sequence number of the generated instance, i.e., if this value of some instance in n, the instance is the n-th instance that was generated.</td>
</tr>
<tr>
<td>numberOfInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the total number of inner instances created for the Multi-Instance Activity.</td>
</tr>
<tr>
<td>numberOfActiveInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the number of currently active inner instances for the Multi-Instance Activity. In case of a sequential Multi-Instance Activity, this value can't be greater than 1. For parallel Multi-Instance Activities, this value can't be greater than the value contained in numberOfInstances.</td>
</tr>
<tr>
<td>numberOfCompletedInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the number of already completed inner instances for the Multi-Instance Activity.</td>
</tr>
<tr>
<td>numberOfTerminatedInstances: integer</td>
<td>This attribute is provided for the outer instance of the Multi-Instance Activity only. This attribute contains the number of terminated inner instances for the Multi-Instance Activity. The sum of numberOfTerminatedInstances, numberOfCompletedInstances, and numberOfActiveInstances always sums up to numberOfInstances.</td>
</tr>
</tbody>
</table>

```
10.3 Items and Data

A traditional requirement of Process modeling is to be able to model the items (physical or information items) that are created, manipulated, and used during the execution of a Process. An important aspect of this is the ability to capture the structure of that data and to query or manipulate that structure.

BPMN does not itself provide a built-in model for describing structure of data or an Expression language for querying that data. Instead it formalizes hooks that allow for externally defined data structures and Expression languages. In addition, BPMN allows for the co-existence of multiple data structure and Expression languages within the same model. The compatibility and verification of these languages is outside the scope of this specification and becomes the responsibility of the tool vendor.

BPMN designates XML Schema and XPath as its default data structure and Expression languages respectively, but vendors are free to substitute their own languages.

10.3.1 Data Modeling

A traditional requirement of Process modeling is to be able to model the items (physical or information items) that are created, manipulated, and used during the execution of a Process.

This requirement is realized in BPMN through various constructs: Data Objects, ItemDefinition, Properties, Data Inputs, Data Outputs, Messages, Input Sets, Output Sets, and Data Associations.

Item-Aware Elements

Several elements in BPMN are subject to store or convey items during process execution. These elements are referenced generally as “item-aware elements.” This is similar to the variable construct common to many languages. As with variables, these elements have an ItemDefinition.

Table 10.50 – Transaction XML schema

```xml
<xsd:element name="transaction" type="tTransaction" substitutionGroup="flowElement"/>
<xsd:complexType name="tTransaction">
  <xsd:complexContent>
    <xsd:extension base="tSubProcess">
      <xsd:attribute name="method" type="tTransactionMethod" default="Compensate"/>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>

<xsd:simpleType name="tTransactionMethod">
  <xsd:restriction base="xsd:string">
    <xsd:enumeration value="Compensate"/>
    <xsd:enumeration value="Image"/>
    <xsd:enumeration value="Store"/>
  </xsd:restriction>
</xsd:simpleType>
```
The data structure these elements hold is specified using an associated ItemDefinition. An ItemAwareElement MAY be underspecified, meaning that the structure attribute of its ItemDefinition is optional if the modeler does not wish to define the structure of the associated data.

The elements in the specification defined as item-aware elements are: Data Objects, Data Object References, Data Stores, Properties, DataInputs and DataOutputs.

Figure 10.50 - ItemAware class diagram

The ItemAwareElement element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.51 presents the additional model associations of the ItemAwareElement element:

Table 10.51 – ItemAwareElement model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>itemSubjectRef: ItemDefinition [0..1]</td>
<td>Specification of the items that are stored or conveyed by the ItemAwareElement.</td>
</tr>
<tr>
<td>dataState: DataState [0..1]</td>
<td>A reference to the DataState, which defines certain states for the data contained in the Item.</td>
</tr>
</tbody>
</table>
Data Objects

The primary construct for modeling data within the Process flow is the DataObject element. A DataObject has a well-defined lifecycle, with resulting access constraints.

DataObject

The Data Object class is an item-aware element. Data Object elements MUST be contained within Process or Sub-Process elements. Data Object elements are visually displayed on a Process diagram. Data Object References are a way to reuse Data Objects in the same diagram. They can specify different states of the same Data Object at different points in a Process. Data Object Reference cannot specify item definitions, and Data Objects cannot specify states. The names of Data Object References are derived by concatenating the name of the referenced Data Object the state of the Data Object Reference in square brackets as follows: <Data Object Name> [ <Data Object Reference State> ]

![DataObject class diagram](image)

Figure 10.51 - DataObject class diagram

The DataObject element inherits the attributes and model associations of FlowElement (see Table 8.44) and ItemAwareElement (Table 10.52). Table 10.54 presents the additional attributes of the DataObject element:
The Data Object Reference element inherits the attributes and model associations of ItemAwareElement (Table 10.52) and FlowElement (see Table 8.44). Table 10.53 presents the additional attributes of the Data Object Reference element:

### Table 10.53 – DataObjectReference attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataObjectRef</td>
<td>The Data Object referenced by the Data Object Reference.</td>
</tr>
</tbody>
</table>

States

Data Object elements can optionally reference a DataState element, which is the state of the data contained in the Data Object (see an example of DataStates used for Data Objects in Figure 7.8). The definition of these states, e.g. possible values and any specific semantic are out of scope of this specification. Therefore, BPMN adopters can use the State element and the BPMN extensibility capabilities to define their states.

The DataState element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.54 presents the additional attributes and model associations of the DataObject element:

### Table 10.54 – DataState attributes and model associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Defines the name of the DataState.</td>
</tr>
</tbody>
</table>

Data Objects representing a Collection of Data

A DataObject element that references an ItemDefinition marked as collection has to be visualized differently, compared to single instance data structures. The notation looks as follows:

Single instance (see Figure 10.52)
Visual representations of Data Objects

Data Object can appear multiple times in a Process diagram. Each of these appearances references the same Data Object instance. Multiple occurrences of a Data Object in a diagram are allowed to simplify diagram connections.

Lifecycle and Accessibility

The lifecycle of a Data Object is tied to the lifecycle of its parent Process or Sub-Process. When a Process or Sub-Process is instantiated, all Data Objects contained within it are also instantiated. When a Process or Sub-Process instance is disposed, all Data Object instances contained within it are also disposed. At this point the data within these instances are no longer available.

The accessibility of a Data Object is driven by its lifecycle. The data within a Data Object can only be accessed when there is guaranteed to be a live Data Object instance present. As a result, a Data Object can only be accessed by its immediate parent (Process or Sub-Process), or by its sibling Flow Elements and their children, including Data Object References referencing the Data Object.

For example: Consider the follow structure.

Process A
  Data object 1
  Task A
  Sub-process A
    Data object 2
    Task B
  Sub-process B
    Data object 3
    Sub-process C
      Data object 4
      Task C
  Task D

“Data object 2” can be accessed by: “Sub-Process A” and “Task B.”

“Data object 3” can be accessed by: “Sub-Process B,” “Sub-Process C,” “Task C,” and “Task D.”

“Data object 4” can be accessed by: “Sub-Process C” and “Task C.”

Data Stores

A DataStore provides a mechanism for Activities to retrieve or update stored information that will persist beyond the scope of the Process. The same DataStore can be visualized, through a Data Store Reference, in one (1) or more places in the Process.

The Data Store Reference is an ItemAwareElement and can thus be used as the source or target for a Data Association. When data flows into or out of a Data Store Reference, it is effectively flowing into or out of the DataStore that is being referenced.

The notation looks as follows (see Figure 10.54):

![Data Store](image)

Figure 10.54 - A Data Store
The **DataStore** element inherits the attributes and model associations of **FlowElement** (see Table 8.44) through its relationship to **RootElement**, and **ItemAwareElement** (see Table 10.51). Table 10.55 presents the additional attributes of the **DataStore** element:

### Table 10.55 – Data Store attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>A descriptive name for the element.</td>
</tr>
<tr>
<td>capacity: integer</td>
<td>Defines the capacity of the Data Store. This is not needed if the isUnlimited attribute is set to true.</td>
</tr>
<tr>
<td>isUnlimited: boolean</td>
<td>If isUnlimited is set to true, then the capacity of a Data Store is set as unlimited and will override any value of the capacity attribute.</td>
</tr>
</tbody>
</table>

The **Data Store Reference** element inherits the attributes and model associations of **FlowElement** (see Table 8.44) and **ItemAwareElement** (see Table 10.51). Table 10.56 presents the additional model associations of the **Data Store Reference** element:
Properties

Properties, like Data Objects, are item-aware elements. But, unlike Data Objects, they are not visually displayed on a Process diagram. Certain flow elements MAY contain properties, in particular only Processes, Activities and Events MAY contain Properties.

The Property class is a DataElement element that acts as a container for data associated with flow elements. Property elements MUST be contained within a FlowElement. Property elements are not visually displayed on a Process diagram.

Table 10.56 – Data Store attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataStoreRef: DataStore</td>
<td>Provides the reference to a global DataStore.</td>
</tr>
</tbody>
</table>

Figure 10.56 - Property class diagram

The Property element inherits the attributes and model associations of ItemAwareElement (Table 10.51). Table 10.54 presents the additional attributes of the Property element:
Lifecycle and Accessibility

The lifecycle of a Property is tied to the lifecycle of its parent Flow Element. When a Flow Element is instantiated, all Properties contained by it are also instantiated. When a Flow Element instance is disposed, all Property instances contained by it are also disposed. At this point the data within these instances are no longer available.

The accessibility of a Property is driven by its lifecycle. The data within a Property can only be accessed when there is guaranteed to be a live Property instance present. As a result, a Property can only be accessed by its parent Process, Sub-Process, or Flow Element. In case the parent is a Process or Sub-Process, then a property can be accesses by the immediate children (including children elements) of that Process or Sub-Process. For example: Consider the follow structure.

```
Process A
  Task A
  Sub-Process A
    Task B
    Sub-Process B
      Sub-Process C
        Task C
    Task D
```

The Properties of “Sub-Process A” are accessible by: “Sub-Process A” and “Task B.”

The Properties of “Task C” are accessible by: “Task C.”

Data Inputs and Outputs

Activities and Processes often need data in order to execute. In addition they can produce data during or as a result of execution. Data requirements are captured as Data Inputs and InputSets. Data that is produced is captured using Data Outputs and OutputSets. These elements are aggregated in a InputOutputSpecification class.

Certain Activities and CallableElements contain a InputOutputSpecification element to describe their data requirements. Execution semantics are defined for the InputOutputSpecification and they apply the same way to all elements that extend it. Not every Activity type defines inputs and outputs, only Tasks, CallableElements (Global Tasks and Processes) MAY define their data requirements. Embedded Sub-Processes MUST NOT define Data Inputs and Data Outputs directly, however they MAY define them indirectly via MultiInstanceLoopCharacteristics.
The `InputOutputSpecification` element inherits the attributes and model associations of `BaseElement` (see Table 8.5). Figure 10.54 presents the additional attributes and model associations of the `InputOutputSpecification` element:
Data Input

A Data Input is a declaration that a particular kind of data will be used as input of the InputOutputSpecification. There may be multiple Data Inputs associated with an InputOutputSpecification.

The Data Input is an item-aware element. Data Inputs are visually displayed on a Process diagram to show the inputs to the top-level Process or to show the inputs of a called Process (i.e. one that is referenced by a Call Activity, where the Call Activity has been expanded to show the called Process within the context of a calling Process).

- Visualized Data Inputs have the same notation as Data Objects, except that they MUST contain a small, unfilled block arrow (see Figure 10.58).
- Data Inputs MAY have incoming Data Associations.
  - If the Data Input is directly contained by the top-level Process, it MUST not be the target of Data Associations within the underlying model. Only Data Inputs that are contained by Activities or Events MAY be the target of Data Associations in the model.
  - If the Process is being called from a Call Activity, the Data Associations that target the Data Inputs of the Call Activity in the underlying model MAY be visualized such that they connect to the corresponding Data Inputs of the called Process, visually crossing the Call Activity boundary. But note that this is visualization only. In the underlying model, the Data Associations target the Data Inputs of the Call Activity and not the Data Inputs of the called Process.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>inputSets: InputSet [1..*]</td>
<td>A reference to the InputSets defined by the InputOutputSpecification. Every InputOutputSpecification MUST define at least one InputSet.</td>

<td>A reference to the OutputSets defined by the InputOutputSpecification. Every Data Interface MUST define at least one OutputSet.</td>
</tr>
<tr>
<td>dataInputs: DataInput [0..*]</td>
<td>An optional reference to the Data Inputs of the InputOutputSpecification. If the InputOutputSpecification defines no Data Input, it means no data is REQUIRED to start the Activity. This is an ordered set.</td>
</tr>
<tr>
<td>dataOutputs: DataOutput [0..*]</td>
<td>An optional reference to the Data Outputs of the InputOutputSpecification. If the InputOutputSpecification defines no Data Output, it means no data is REQUIRED to finish the Activity. This is an ordered set.</td>
</tr>
</tbody>
</table>
The “optional” attribute defines if a **DataInput** is valid even if the state is “unavailable”. The default value is `false`. If the value of this attribute is `true`, then the execution of the **Activity** will not begin until a value is assigned to the **DataInput** element, through the corresponding **Data Associations**.

**States**

**DataInput** elements can optionally reference a **DataState** element, which is the state of the data contained in the **DataInput**. The definition of these states, e.g., possible values, and any specific semantics are out of scope of this specification. Therefore, **BPMN** adopters can use the **DataState** element and the **BPMN** extensibility capabilities to define their states.

![Data Input class diagram](image)

The **DataInput** element inherits the attributes and model associations of **BaseElement** (see Table 8.5) and **ItemAwareElement** (Table 10.52). Table 10.59 presents the additional attributes and model associations of the **DataInput** element:
A **Data Output** is a declaration that a particular kind of data can be produced as output of the **InputOutputSpecification**. There MAY be multiple **Data Outputs** associated with a **InputOutputSpecification**.

The **Data Output** is an item-aware element. **Data Output** are visually displayed on a top-level **Process** diagram to show the outputs of the **Process** (i.e. one that is referenced by a Call Activity, where the **Call Activity** has been expanded to show the called **Process** within the context of a calling **Process**).

- **Visualized Data Outputs** have the same notation as **Data Objects**, except that they MUST contain a small, filled block arrow (see Figure 10.60).

- **Data Outputs** MAY have **outgoing DataAssociations**.
  - If the **Data Output** is directly contained by the top-level **Process**, it MUST not be the source of **Data Associations** within the underlying model. Only **Data Outputs** that are contained by **Activities** or **Events** MAY be the target of **Data Associations** in the model.
  - If the **Process** is being called from a **Call Activity**, the **Data Associations** that target the **Data Outputs** of the **Call Activity** in the underlying model MAY be visualized such that they connect to the corresponding **Data Outputs** of the called **Process**, visually crossing the **Call Activity** boundary. But note that this is visualization only. In the underlying model, the **Data Associations** originate the **Data Outputs** of the **Call Activity** and not the **Data Outputs** of the called **Process**.

Figure 10.60 - A Data Output

States

DataOutput elements can optionally reference a DataState element, which is the state of the data contained in the DataOutput. The definition of these states, e.g., possible values, and any specific semantics are out of scope of this specification. Therefore, BPMN adopters can use the DataState element and the BPMN extensibility capabilities to define their states.

Figure 10.61 - Data Output class diagram

The DataOutput element inherits the attributes and model associations of BaseElement (see Table 8.5) and ItemAwareElement (Table 10.52). Table 10.60 presents the additional attributes and model associations of the DataInput element:
The following describes the mapping of data inputs and outputs to the specific Activity and Event implementations:

**Service Task Mapping**

If the Service Task is associated with an Operation there MUST be a Message Data Input on the Service Task and it MUST have an itemDefinition equivalent to the one defined by the Message referred to by the inMessageRef attribute of the operation. If the operation defines output Messages, there MUST be a single Data Output and it MUST have an itemDefinition equivalent to the one defined by Message referred to by the outMessageRef attribute of the Operation.

**Send Task Mapping**

If the Send Task is associated with a Message, there MUST be at most inputSet set and at most one Data Input on the Send Task. If the Data Input is present, it MUST have an itemDefinition equivalent to the one defined by the associated Message. If the Data Input is not present, the Message will not be populated with data at execution time.

**Recieve Task Mapping**

If the Receive Task is associated with a Message, there MUST be at most outputSet set and at most one Data Output on the Receive Task. If the Data Output is present, it MUST have an itemDefinition equivalent to the one defined by the associated Message. If the Data Output is not present, the payload within the Message will not flow out of the Receive Task and into the Process.

**User Task Mapping**

User Tasks have access to the Data Input, Data Output and the data aware elements available in the scope of the User Task.
Call Activity Mapping

The DataInputs and DataOutputs of the Call Activity are mapped to the corresponding elements in the CallableElement without any explicit DataAssociation.

Script Task Mapping

Script Tasks have access to the Data Input, Data Output and the data aware elements available in the scope of the Script Task.

Events

If any of the EventDefinitions for the Event is associated with an element that has an ItemDefinition (such as a Message, Escalation, Error, or Signal), the following constraints apply:

- If the Event is associated with multiple EventDefinitions, there MUST be one Data Input (in the case of throw Events) or one Data Output (in the case of catch Event) for each EventDefinition. The order of the EventDefinitions and the order of the Data Inputs/Outputs determine which Data Input/Output corresponds with which EventDefinition.

- For each EventDefinition and Data Input/Output pair, if the Data Input/Output is present, it MUST have an ItemDefinition equivalent to the one defined by the Message, Escalation, Error, or Signal on the associated EventDefinition. In the case of a throw Event, if the Data Input is not present, the Message, Escalation, Error, or Signal will not be populated with data. In the case of a catch Event, if the Data Output is not present, the payload within the Message, Escalation, Error, or Signal will not flow out of the Event and into the Process.

InputSet

An InputSet is a collection of DataInput elements that together define a valid set of data inputs for a InputOutputSpecification. An InputOutputSpecification MUST have at least one InputSet element. An InputSet MAY reference zero or more DataInput elements. A single DataInput MAY be associated with multiple InputSet elements, but it MUST always be referenced by at least one InputSet.

An “empty” InputSet, one that references no DataInput elements, signifies that the Activity requires no data to start executing (this implies that either there are no data inputs or they are referenced by another input set).

InputSet elements are contained by InputOutputSpecification elements; the order in which these elements are included defines the order in which they will be evaluated.
The `InputSet` element inherits the attributes and model associations of `BaseElement` (see Table 8.5). Table 10.61 presents the additional attributes and model associations of the `InputSet` element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>name</code>: string [0..1]</td>
<td>A descriptive name for the input set.</td>
</tr>
<tr>
<td><code>dataInputRefs</code>: DataInput [0..*]</td>
<td>The <code>DataInput</code> elements that collectively make up this data requirement.</td>
</tr>
<tr>
<td><code>optionalInputRefs</code>: DataInput [0..*]</td>
<td>The <code>DataInput</code> elements that are a part of the <code>InputSet</code> that can be in the state of “unavailable” when the <code>Activity</code> starts executing. This association MUST NOT reference a <code>DataInput</code> that is not listed in the <code>dataInputRefs</code>.</td>
</tr>
<tr>
<td><code>whileExecutingInputRefs</code>: DataInput [0..*]</td>
<td>The <code>DataInput</code> elements that are a part of the <code>InputSet</code> that can be evaluated while the <code>Activity</code> is executing. This association MUST NOT reference a <code>DataInput</code> that is not listed in the <code>dataInputRefs</code>.</td>
</tr>
<tr>
<td><code>outputSetRefs</code>: OutputSet [0..*]</td>
<td>Specifies an <code>Input/Output</code> rule that defines which <code>OutputSet</code> is expected to be created by the <code>Activity</code> when this <code>InputSet</code> became valid. This attribute is paired with the <code>inputSetRefs</code> attribute of <code>OutputSets</code>. This combination replaces the <code>IORules</code> attribute for <code>Activities</code> in BPMN 1.2.</td>
</tr>
</tbody>
</table>
OutputSet

An OutputSet is a collection of DataOutputs elements that together can be produced as output from an Activity or Event. An InputOutputSpecification element MUST define at least one OutputSet element. An OutputSet MAY reference zero or more DataOutput elements. A single DataOutput MAY be associated with multiple OutputSet elements, but it MUST always be referenced by at least one OutputSet.

An “empty” OutputSet, one that is associated with no DataOutput elements, signifies that the Activity produces no data.

The implementation of the element where the OutputSet is defined determines the OutputSet that will be produced. So it is up to the Activity implementation or the Event, to define which OutputSet will be produced.

Figure 10.63 - OutputSet class diagram

The OutputSet element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.62 presents the additional attributes and model associations of the OutputSet element:
Data Associations

Data Associations are used to move data between Data Objects, Properties, and inputs and outputs of Activities, Processes, and GlobalTasks. Tokens do not flow along a Data Association, and as a result they have no direct effect on the flow of the Process.

The purpose of retrieving data from Data Objects or Process Data Inputs is to fill the Activities inputs and later push the output values from the execution of the Activity back into Data Objects or Process Data Outputs.

DataAssociation

The DataAssociation class is a BaseElement contained by an Activity or Event, used to model how data is pushed into or pulled from item-aware elements. DataAssociation elements have one or more sources and a target; the source of the association is copied into the target.

The ItemDefinition from the souceRef and targetRef MUST have the same ItemDefinition or the DataAssociation MUST have a transformation Expression that transforms the source ItemDefinition into the target ItemDefinition.
Figure 10.64 - DataAssociation class diagram

 Optionally, **Data Associations** can be visually represented in the diagram by using the Association connector style (see Figure 10.65 and Figure 10.66).

Figure 10.65 - A Data Association

The core concepts of a DataAssociation are that they have sources, a target, and an optional transformation.

When a data association is “executed,” data is copied to the target. What is copied depends if there is a transformation defined or not.

If there is no transformation defined or referenced, then only one source MUST be defined, and the contents of this source will be copied into the target.
If there is a transformation defined or referenced, then this transformation Expression will be evaluated and the result of the evaluation is copied into the target. There can be zero (0) to many sources defined in this case, but there is no requirement that these sources are used inside the Expression.

In any case, sources are used to define if the data association can be “executed,” if any of the sources is in the state of “unavailable,” then the data association cannot be executed, and the Activity or Event where the data association is defined MUST wait until this condition is met.

Data Associations are always contained within another element that defines when these data associations are going to be executed. Activities define two (2) sets of data associations, while Events define only 1 (one).

For Events, there is only one set, but they are used differently for catch or throw Events. For a catch Event, data associations are used to push data from the Message received into Data Objects and properties. For a throw Event, data associations are used to fill the Message that is being thrown.

As DataAssociation are used in different stages of the Process and Activity lifecycle, the possible sources and targets vary according to that stage. This defines the scope of possible elements that can be referenced as source and target. For example: when an Activity starts executing, the scope of valid targets include the Activity data inputs, while at the end of the Activity execution, the scope of valid sources include Activity data outputs.

The DataAssociation element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.63 presents the additional model associations of the DataAssociation element:

<table>

</tr>
</tbody>
</table>

Assignment

The Assignment class is used to specify a simple mapping of data elements using a specified Expression language.

The default Expression language for all Expressions is specified in the Definitions element, using the expressionLanguage attribute. It can also be overridden on each individual Assignment using the same attribute.

The Assignment element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.64 presents the additional attributes of the Assignment element:
The **DataInputAssociation** can be used to associate an ItemAwareElement element with a DataInput contained in an Activity. The source of such a DataAssociation can be every ItemAwareElement accessible in the current scope, e.g., a Data Object, a Property or an Expression.

The DataInputAssociation element inherits the attributes and model associations of DataAssociation (see Table 10.64), but does not contain any additional attributes or model associations.

### DataOutputAssociation

The **DataOutputAssociation** can be used to associate a DataOutput contained within an ACTIVITY with any ItemAwareElement accessible in the scope the association will be executed in. The target of such a DataAssociation can be every ItemAwareElement accessible in the current scope, e.g., a Data Object, a Property or an Expression.

The DataOutputAssociation element inherits the attributes and model associations of DataAssociation (see Table 10.64), but does not contain any additional attributes or model associations.

### Data Objects associated with a Sequence Flow

Figure 10.67 repeats Figure 10.66, above, and shows how Data Associations are used to represent inputs and outputs of Activities.

Alternatively, Data Objects MAY be directly associated with a Sequence Flow connector (see Figure 10.68) to represent the same input/output relationships. This is a visual short cut that normalizes two Data Associations (e.g., as seen in Figure 10.67, above): one from a item-aware element (e.g., an Activity) contained by the source of the Sequence Flow, connecting to the Data Object, and the other from the Data Object connecting to a item-aware element contained by the target of the Sequence Flow.

Business Process Model and Notation, v2.0 231
10.3.2 Execution Semantics for Data

When an element that defines a InputOutputSpecification is ready to begin execution by means of Sequence Flow or Event being caught, the inputs of the interface are filled with data coming from elements in the context, such as Data Objects or Properties. The way to represent these assignments is the Data Association elements.

Each defined InputSet element will be evaluated in the order they are included in the InputOutputSpecification. For each InputSet, the data inputs it references will be evaluated if it is valid.

All data associations that define as target the data input will be evaluated, and if any of the sources of the data association is “unavailable,” then the InputSet is “unavailable” and the next InputSet is evaluated.

The first InputSet where all data inputs are “available” (by means of data associations) is used to start the execution of the Activity. If no InputSet is “available,” then the execution will wait until this condition is met.

The time and frequency of when and how often this condition is evaluated is out of scope this specification. Implementations will wait for the sources of data associations to become available and then re-evaluate the InputSets.

In the case of throw and catch Events, given their nature, the execution semantics for data is different.

When a throw Event is activated, all DataInputAssociations of the event are executed, filling the Data Inputs of the Event. Finally, DataInputs are then copied to the elements thrown by the Event (Messages, Signals, etc). Since there are no InputSets defined for Events, the execution will never wait.

When a catch Event is activated, Data Outputs of the event are filled with the element that triggered the Event. Then all DataOutputAssociations of the Event are executed. There are no OutputSets defined for Events.

To allow invoking a Process from both a Call Activity and via Message Flow, the Start Event and End Event support an additional case.

In the case of a Start Event, the Data Inputs of the enclosing process are available as targets to the DataOutputAssociations of the Event. This way the Process Data Inputs can be filled using the elements that triggered the Start Event.

In the case of a End Event, the Data Outputs of the enclosing process are available as sources to the DataInputAssociations of the Event. This way the resulting elements of the End Event can use the Process Data Outputs as sources.
Once an InputSet becomes "available", all Data Associations whose target is any of the Data Inputs of the InputSet are executed. These executions fill the Activity Data Inputs and the execution of the Activity can begin. When an Activity finishes execution, all Data Associations whose sources are any of the Data Outputs of the OutputSet are executed. These executions copy the values from the Data Outputs back to the container's context (Data Object, Properties, etc).

Execution Semantics for DataAssociation

The execution of any Data Associations MUST follow these semantics:

- If the Data Association specifies a "transformation" Expression, this expression is evaluated and the result is copied to the targetRef. This operation replaces completely the previous value of the targetRef element.

- For each "assignment" element specified:
  - Evaluate the Assignment's "from" expression and obtain the *source value*.
  - Evaluate the Assignment's "to" expression and obtain the *target element*. The *target element* can be any element in the context or a sub-element of it (e.g. a DataObject or a sub-element of it).
  - Copy the *source value* to the *target element*.

- If no "transformation" Expression nor any "assignment" elements are defined in the Data Association:
  - Copy the Data Association "sourceRef" value into the "targetRef". Only one sourceRef element is allowed in this case.

10.3.3 Usage of Data in XPath Expressions

BPMN extensibility mechanism enables the usage of various languages for Expressions and queries. This section describes how XPath is used in BPMN. It introduces a mechanism to access BPMN Data Objects, BPMN Properties, and various instance attributes from XPath Expressions.

The accessibility by the Expression language is defined based on the entities accessibility by the Activity that contains the Expression. All elements accessible from the enclosing element of an XPath Expression MUST be made available to the XPath processor.

BPMN Data Objects and BPMN Properties are defined using ItemDefinition. The XPath binding assumes that the ItemDefinition is either an XSD complex type or an XSD element. If XSD element is used it MUST be manifested as a node-set XPath variable with a single member node. If XSD complex type is used it MUST be manifested as a node-set XPath variable with one member node containing the anonymous document element that contains the actual value of the BPMN Data Object or Property.

Access to BPMN Data Objects

Table 10.65 introduces an XPath function used to access BPMN Data Objects. Argument processName names Process and is of type string. Argument dataObjectName names Data Object and is of type string. It MUST be a literal string.
Because XPath 1.0 functions do not support returning faults, an empty node set is returned in the event of an error.

**Access to BPMN Data Input and Data Output**

Table 10.66 introduces XPath functions used to access BPMN Data Inputs and BPMN Data Outputs. Argument `dataInputName` names a Data Input and is of type string. Argument `dataOutput` names a Data Output and is of type string.

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element getDataInput</strong></td>
<td>This extension function returns the value of the submitted Data Input. Argument <code>dataInputName</code> names a Data Input and is of type string.</td>
</tr>
<tr>
<td><strong>Element getDataOutput</strong></td>
<td>This extension function returns the value of the submitted Data Output. Argument <code>dataOutputName</code> names a Data Output.</td>
</tr>
</tbody>
</table>

**Access to BPMN Properties**

Table 10.67 introduces XPath functions used to access BPMN Properties.

Argument `processName` names Process and is of type string. Argument `propertyName` names property and is of type string. Argument `activityName` names Activity and is of type string. Argument `eventName` names Event and is of type string. These strings MUST be literal strings. The XPath extension functions return value of the submitted property.

Because XPath 1.0 functions do not support returning faults, an empty node set is returned in the event of an error.
Table 10.67 – XPath Extension Functions for Properties

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element getProcessProperty</strong> ('processName', 'propertyName')</td>
<td>This extension function returns value of submitted Process property. Argument processName is optional. If omitted, the Process enclosing the Activity that contains the Expression is assumed. In order to access Properties defined in a parent Process the processName MUST be used. Otherwise it MUST be omitted.</td>
</tr>
<tr>
<td><strong>Element getActivityProperty</strong> ('activityName', 'propertyName')</td>
<td>This extension function returns value of submitted Activity property.</td>
</tr>
<tr>
<td><strong>Element getEventProperty</strong> ('eventName', 'propertyName')</td>
<td>This extension function returns value of submitted Event property.</td>
</tr>
</tbody>
</table>

For BPMN Instance Attributes

Table 10.68 introduces XPath functions used to access BPMN instance Attributes.

Argument **processName** names Process and is of type string. Argument **attributeName** names instance attribute and is of type string. Argument **activityName** names Activity and is of type string. These strings MUST be literal strings.

These functions return value of the submitted instance Activity. Because XPath 1.0 functions do not support returning faults, an empty node set is returned in the event of an error.

Table 10.68 – XPath extension functions for instance attributes

<table>
<thead>
<tr>
<th>XPath Extension Function</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element getProcessInstanceAttribute</strong> ('processName','attributeName')</td>
<td>This extension function returns value of submitted Process instance attribute. Argument processName is optional. If omitted, the Process enclosing the Activity that contains the Expression is assumed. In order to access instance Attributes of a parent Process the processName MUST be used. Otherwise it MUST be omitted.</td>
</tr>
<tr>
<td><strong>Element getChoreographyInstanceAttribute</strong> ('attributeName')</td>
<td>This extension function returns value of submitted Choreography instance attribute.</td>
</tr>
<tr>
<td><strong>Element getActivityInstanceAttribute</strong> ('activityName', 'attributeName')</td>
<td>This extension function returns value of submitted Activity instance attribute. User Task and loop are examples of Activities.</td>
</tr>
</tbody>
</table>

    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```
10.4 Events

An Event is something that “happens” during the course of a Process. These Events affect the flow of the Process and usually have a cause or an impact and in general require or allow for a reaction. The term “event” is general enough to cover many things in a Process. The start of an Activity, the end of an Activity, the change of state of a document, a Message that arrives, etc., all could be considered Events.

Events allow for the description of “event-driven” Processes. In these Processes, there are three main types of Events:

- **Start Events** (see page 245), which indicate where a Process will start.
- **End Events** (see page 253), which indicate where a path of a Process will end.
- **Intermediate Events** (see page 257), which indicate where something happens somewhere between the start and end of a Process.

Within these three types, Events come in two flavors:

- **Events** that catch a trigger. All Start Events and some Intermediate Events are catching Events.
- **Events** that throw a Result. All End Events and some Intermediate Events are throwing Events that MAY eventually be caught by another Event. Typically the trigger carries information out of the scope where the throw Event occurred into the scope of the catching Events. The throwing of a trigger MAY be either implicit as defined by this standard or an extension to it or explicit by a throw Event.

Table 10.80 – Property XML schema

```xml
<xsd:element name="property" type="tProperty" />
<xsd:complexType name="tProperty">
    <xsd:complexContent>
        <xsd:extension base="tBaseElement">
            <xsd:attribute name="name" type="xsd:string"/>
            <xsd:attribute name="itemSubjectRef" type="xsd:QName"/>
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```
10.4.1 Concepts

Depending on the type of the Event there are different strategies to forward the trigger to catching Events: publication, direct resolution, propagation, cancellations, and compensations.

With publication a trigger MAY be received by any catching Events in any scope of the system where the trigger is published. Events for which publication is used are grouped to Conversations. Published Events MAY participate in several Conversations. Messages are triggers, which are generated outside of the Pool they are published in. They typically describe B2B communication between different Processes in different Pools. When Messages need to reach a specific Process instance, correlation is used to identify the particular instance. Signals are triggers generated in the Pool they are published. They are typically used for broadcast communication within and across Processes, across Pools, and between Process diagrams.

Timer and Conditional triggers are implicitly thrown. When they are activated they wait for a time based or status based condition respectively to trigger the catch Event.
A trigger that is propagated is forwarded from the location where the Event has been thrown to the innermost enclosing scope instance (e.g., Process level) which has an attached Event being able to catch the trigger. Error triggers are critical and suspend execution at the location of throwing. Escalations are non critical and execution continues at the location of throwing. If no catching Event is found for an error or escalation trigger, this trigger is unresolved.

Termination, compensation, and cancellation are directed towards a Process or a specific Activity instance. Termination indicates that all Activities in the Process or Activity should be immediately ended. This includes all instances of multi-instances. It is ended without compensation or Event handling.

Compensation of a successfully completed Activity triggers its compensation handler. The compensation handler is either user defined or implicit. The implicit compensation handler of a Sub Process calls all compensation handlers of its enclosed Activities in the reverse order of Sequence Flow dependencies. If compensation is invoked for an Activity that has not yet completed, or has not completed successfully, nothing happens (in particular, no error is raised).

Cancellation will terminate all running Activities and compensate all successfully completed Activities in the Sub-Process it is applied to. If the Sub-Process is a Transaction, the Transaction is rolled back.

Data Modeling and Events

Some Events (like the Message, Escalation, Error, Signal, and Multiple Event) have the capability to carry data. Data Association is used to push data from a Catch Event to a data element. For such Events, the following constraints apply:

- If the Event is associated with multiple EventDefinitions, there MUST be one Data Input (in the case of throw Events) or one Data Output (in the case of catch Events) for each EventDefinition. The order of the EventDefinitions and the order of the Data Inputs/Outputs determine which Data Input/Output corresponds with which EventDefinition.

- For each EventDefinition and Data Input/Output pair, if the Data Input/Output is present, it MUST have an ItemDefinition equivalent to the one defined by the Message, Escalation, Error, or Signal on the associated EventDefinition. In the case of a throw Event, if the Data Input is not present, the Message, Escalation, Error, or Signal will not be populated with data. In the case of a catch Event, if the Data Output is not present, the payload within the Message, Escalation, Error, or Signal will not flow out of the Event and into the Process.

The execution behavior is then as follows:

- For throw Events: When the Event is activated, the data in the Data Input is automatically assigned to the Message, Escalation, Error, or Signal referenced by the corresponding EventDefinition.

- For catch Events: When the trigger of the Event occurs (for example, the Message is received), the data is automatically assigned to the Data Output that corresponds to the EventDefinition that described that trigger.

Common Event attributes

The Event element inherits the attributes and model associations of FlowElement (see Table 8.44). Table 10.81 presents the additional model associations of the Event element:
Common Catch Event attributes

The `CatchEvent` element inherits the attributes and model associations of `Event` element (see Table 10.81). Table 10.82 presents the additional attributes and model associations of the `CatchEvent` element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
</table>
| `eventDefinitionRefs`: EventDefinition [0..*] | References the reusable EventDefinitions that are triggers expected for a `catch Event`. Reusable EventDefinitions are defined as top-level elements. These EventDefinitions can be shared by different `catch` and `throw` Events.  
  - If there is no EventDefinition defined, then this is considered a `catch None Event` and the Event will not have an internal marker (see Figure 10.91).  
  - If there is more than one EventDefinition defined, this is considered a `Catch Multiple Event` and the Event will have the pentagon internal marker (see Figure 10.90).  
  This is an ordered set. |
| `eventDefinitions`: EventDefinition [0..*] | Defines the event EventDefinitions that are triggers expected for a `catch Event`. These EventDefinitions are only valid inside the current Event.  
  - If there is no EventDefinition defined, then this is considered a `catch None Event` and the Event will not have an internal marker (see Figure 10.91).  
  - If there is more than one EventDefinition defined, this is considered a `catch Multiple Event` and the Event will have the pentagon internal marker (see Figure 10.90).  
  This is an ordered set. |
| `dataOutputAssociations`: Data OutputAssociation [0..*] | The Data Associations of the `catch Event`.  
  The dataOutputAssociation of a `catch Event` is used to assign data from the Event to a data element that is in the scope of the Event.  
  For a `catch Multiple Event`, multiple Data Associations might be REQUIRED, depending on the individual triggers of the Event. |
Common Throw Event Attributes

The `ThrowEvent` element inherits the attributes and model associations of `Event` element (see Table 10.81). Table 10.83 presents the additional attributes and model associations of the `ThrowEvent` element.

</tbody>
</table>
Implicit Throw Event

A sub-type of throw Event is the ImplicitThrowEvent. This is a non-graphical Event that is used for Multi-Instance Activities (see page 198). The ImplicitThrowEvent element inherits the attributes and model associations of ThrowEvent (see Table 10.84), but does not have any additional attributes or model associations.

10.4.2 Start Event

As the name implies, the Start Event indicates where a particular Process will start. In terms of Sequence Flows, the Start Event starts the flow of the Process, and thus, will not have any incoming Sequence Flows—no Sequence Flow can connect to a Start Event.

The Start Event shares the same basic shape of the Intermediate Event and End Event, a circle with an open center so that markers can be placed within the circle to indicate variations of the Event.

- A Start Event is a circle that MUST be drawn with a single thin line (see Figure 10.70).
- The use of text, color, size, and lines for a Start Event MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41 with the exception that:
  - The thickness of the line MUST remain thin so that the Start Event can be distinguished from the Intermediate and End Events.

![Figure 10.70 - Start Event](image)

Throughout this document, we discuss how Sequence Flows are used within a Process. To facilitate this discussion, we employ the concept of a token that will traverse the Sequence Flows and pass through the elements in the Process. A token is a theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it “traverses” the structure of the Process.

Note – A token does not traverse a Message Flow since it is a Message that is passed down a Message Flow (as the name implies).
Semantics of the **Start Event** include:

- A **Start Event** is **OPTIONAL**: a **Process** level—a top-level **Process**, a **Sub-Process** (embedded), or a Global **Process** (called **Process**)—MAY (is NOT REQUIRED to) have a **Start Event**.

**Note** – A **Process** MAY have more than one **Process** level (i.e., it can include Expanded **Sub-Processes** or **Call Activities** that call other **Processes**). The use of **Start** and **End Events** is independent for each level of the Diagram.

- If a **Process** is complex and/or the starting conditions are not obvious, then it is RECOMMENDED that a **Start Event** be used.
- If a **Start Event** is not used, then the implicit **Start Event** for the **Process** SHALL NOT have a **trigger**.
- If there is an **End Event**, then there MUST be at least one **Start Event**.
- All **Flow Objects** that do not have an **incoming Sequence Flow** (i.e., are not a target of a **Sequence Flow**) SHALL be instantiated when the **Process** is instantiated.
- Exceptions to this are **Activities** that are defined as being **Compensation Activities** (it has the **Compensation** marker). **Compensation Activities** are not considered a part of the *normal flow* and MUST NOT be instantiated when the **Process** is instantiated. See page 311 for more information on **Compensation Activities**.
- An exception to this is a catching **Link Intermediate Event**, which is not allowed to have **incoming Sequence Flows**. See page 275 for more information on **Link Intermediate Events**.
- An exception to this is an **Event Sub-Process**, which is not allowed to have **incoming Sequence Flows** and will only be instantiated when its **Start Event** is triggered. See page 181 for more information on **Event Sub-Processes**.
- There MAY be multiple **Start Events** for a given **Process** level.
- Each **Start Event** is an independent **Event**. That is, a **Process instance** SHALL be generated when the **Start Event** is triggered.

If the **Process** is used as a global **Process** (a callable **Process** that can be invoke from **Call Activities** of other **Processes**) and there are multiple **None Start Events**, then when flow is transferred from the parent **Process** to the global **Process**, only one of the global **Process’s Start Events** will be triggered. The **targetRef** attribute of a **Sequence Flow incoming** to the **Call Activity** object can be extended to identify the appropriate **Start Event**.

**Note** – The behavior of **Process** can be harder to understand if there are multiple **Start Events**. It is RECOMMENDED that this feature be used sparingly and that the modeler be aware that other readers of the Diagram could have difficulty understanding the intent of the Diagram.

When the **trigger** for a **Start Event** occurs, a new **Process** will be instantiated and a **token** will be generated for each **outgoing Sequence Flow** from that **Event**.

**Start Event Triggers**

**Start Events** can be used for three types of **Processes**:

- **Top-level Processes**
- **Sub-Processes** *(embedded)*
- **Global Process** *(called)*
- **Event Sub-Processes**

The next three (3) sections describe the types of **Start Events** that can be used for each of these three types of **Processes**.

**Start Events for Top-level Processes**

There are many ways that *top-level Processes* can be started (instantiated). The *trigger* for a **Start Event** is designed to show the general mechanisms that will instantiate that particular **Process**. There are seven (7) types of **Start Events** for *top-level Processes* in BPMN (see Table 10.84): None, Message, Timer, Conditional, Signal, Multiple, and Parallel.

A top-level **Process** that has at least one (1) **None Start Event** MAY be called by a **Call Activity** in another **Process**. The **None Start Event** is used for invoking the **Process** from the **Call Activity**. All other types of **Start Events** are only applicable when the **Process** is used as a top-level **Process**.

**Table 10.84 – Top-Level Process Start Event Types**

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The <strong>None Start Event</strong> does not have a defined trigger. There is no specific EventDefinition subclass (see page 268) for <strong>None Start Events</strong>. If the <strong>Start Event</strong> has no associated EventDefinition, then the Event MUST be displayed without a marker (see the figure on the right).</td>
<td><img src="figure.png" alt="None" /></td>
</tr>
<tr>
<td>Message</td>
<td>A <strong>Message</strong> arrives from a <strong>Participant</strong> and triggers the start of the <strong>Process</strong>. See page 93 for more details on <strong>Messages</strong>. If there is only one (1) EventDefinition associated with the <strong>Start Event</strong> and that EventDefinition is of the subclass MessageEventDefinition, then the <strong>Event</strong> is a <strong>Message Start Event</strong> and MUST be displayed with an envelope marker (see the figure to the right). The actual <strong>Participant</strong> from which the <strong>Message</strong> is received can be identified by connecting the <strong>Event</strong> to a <strong>Participant</strong> using a <strong>Message Flow</strong> within the definitional <strong>Collaboration</strong> of the <strong>Process</strong> – see Table 10.1.</td>
<td><img src="figure.png" alt="Message" /></td>
</tr>
<tr>
<td>Timer</td>
<td>A specific time-date or a specific cycle (e.g., every Monday at 9am) can be set that will trigger the start of the <strong>Process</strong>. If there is only one (1) EventDefinition associated with the <strong>Start Event</strong> and that EventDefinition is of the subclass TimerEventDefinition, then the <strong>Event</strong> is a <strong>Timer Start Event</strong> and MUST be displayed with a clock marker (see the figure to the right).</td>
<td><img src="figure.png" alt="Timer" /></td>
</tr>
</tbody>
</table>
Start Events for Sub-Processes

There is only one (1) type of Start Event for Sub-Processes in BPMN (see Figure 10.82): None.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Conditional</td>
<td>This type of event is triggered when a condition such as “S&amp;P 500 changes by more than 10% since opening”, or “Temperature above 300°C” become true. The condition Expression for the Event MUST become false and then true before the Event can be triggered again. The Condition Expression of a Conditional Start Event MUST NOT refer to the data context or instance attribute of the Process (as the Process instance has not yet been created). Instead, it MAY refer to static Process attributes and states of entities in the environment. The specification of mechanisms to access such states is out of scope of the standard. If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass ConditionalEventDefinition, then the Event is a Conditional Start Event and MUST be displayed with a lined paper marker (see the figure to the right).</td>
</tr>
<tr>
<td>Signal</td>
<td>A Signal arrives that has been broadcast from another Process and triggers the start of the Process. Note that the Signal is not a Message, which has a specific target for the Message. Multiple Processes can have Start Events that are triggered from the same broadcasted Signal. If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass SignalEventDefinition, then the Event is a Signal Start Event and MUST be displayed with a triangle marker (see the figure to the right).</td>
</tr>
<tr>
<td>Multiple</td>
<td>This means that there are multiple ways of triggering the Process. Only one of them is REQUIRED. There is no specific EventDefinition subclass for Multiple Start Events. If the Start Event has more than one associated EventDefinition, then the Event MUST be displayed with the Multiple Event marker (a pentagon—see the upper figure to the right).</td>
</tr>
<tr>
<td>Parallel Multiple</td>
<td>This means that there are multiple triggers REQUIRED before the Process can be instantiated. All of the types of triggers that are listed in the Start Event MUST be triggered before the Process is instantiated. There is no specific EventDefinition subclass for Parallel Multiple Start Events. If the Start Event has more than one associated EventDefinition and the parallelMultiple attribute of the Start Event is true, then the Event MUST be displayed with the Parallel Multiple Event marker (an open plus sign—see the figure to the right).</td>
</tr>
</tbody>
</table>
Start Events for Event Sub-Processes

A Start Event can also initiate an inline Event Sub-Process (see page 181). In that case, the same Event types as for boundary Events are allowed (see Table 10.86), namely: Message, Timer, Escalation, Error, Compensation, Conditional, Signal, Multiple, and Parallel.

- An Event Sub-Process MUST have a single Start Event.

### Table 10.85 – Sub-Process Start Event Types

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The None Start Event is used for all Sub-Processes, either embedded or called (reusable). Other types of triggers are not used for a Sub-Process, since the flow of the Process (a token) from the parent Process is the trigger of the Sub-Process. If the Sub-Process is called (reusable) and has multiple Start Events, some of the other Start Events MAY have triggers, but these Start Events would not be used in the context of a Sub-Process. When the other Start Events are triggered, they would instantiate top-level Processes.</td>
<td><img src="image" alt="Marker" /></td>
</tr>
</tbody>
</table>

### Table 10.86 – Event Sub-Process Start Event Types

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message</td>
<td>If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass MessageEventDefinition, then the Event is a Message Start Event and uses an envelope marker (see the figures to the right). For a Message Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right). For a Message Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right). The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10.1.</td>
<td><img src="image" alt="Interrupting" /> <img src="image" alt="Non-Interrupting" /></td>
</tr>
</tbody>
</table>
Timer

If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass TimerEventDefinition, then the Event is a Timer Start Event and uses a clock marker (see the figures to the right).

For a Timer Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For a Timer Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).

Escalation

Escalation Event Sub-Processes implement measures to expedite the completion of a business Activity, should it not satisfy a constraint specified on its execution (such as a time-based deadline).

The Escalation Start Event is only allowed for triggering an in-line Event Sub-Process.

If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass EscalationEventDefinition, then the Event is an Escalation Start Event and uses an arrowhead marker (see the figures to the right).

For an Escalation Event Sub-Process that interrupts its containing Process, the boundary of the Event is solid (see the upper figure to the right).

For an Escalation Event Sub-Process that does not interrupt its containing Process, the boundary of the Event is dashed (see the lower figure on the right).

Error

The Error Start Event is only allowed for triggering an in-line Event Sub-Process.

If there is only one (1) EventDefinition associated with the Start Event and that EventDefinition is of the subclass ErrorEventDefinition, then the Event is an Error Start Event and uses a lightning marker (see the figures to the right).

Given the nature of Errors, an Event Sub-Process with an Error trigger will always interrupt its containing Process.
### Table 10.86 – Event Sub-Process Start Event Types

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compensation</td>
<td>The <strong>Compensation Start Event</strong> is only allowed for triggering an in-line <strong>Compensation Event Sub-Process</strong> (see “Compensation Handler” on page 311). This type of <strong>Event</strong> is triggered when compensation occurs. If there is only one (1) <strong>EventDefinition</strong> associated with the <strong>Start Event</strong> and that <strong>EventDefinition</strong> is of the subclass CompensationEventDefinition, then the <strong>Event</strong> is a <strong>Compensation Start Event</strong> and uses a double triangle marker (see the figure to the right). This <strong>Event</strong> does not interrupt the <strong>Process</strong> since the <strong>Process</strong> has to be completed before this <strong>Event</strong> can be triggered.</td>
</tr>
<tr>
<td>Conditional</td>
<td>If there is only one (1) <strong>EventDefinition</strong> associated with the <strong>Start Event</strong> and that <strong>EventDefinition</strong> is of the subclass ConditionalEventDefinition, then the <strong>Event</strong> is a <strong>Conditional Start Event</strong> and uses an lined page marker (see the figures to the right). For a <strong>Conditional Event Sub-Process</strong> that interrupts its containing <strong>Process</strong>, then the boundary of the <strong>Event</strong> is solid (see the upper figure to the right). For a <strong>Conditional Event Sub-Process</strong> that does not interrupt its containing <strong>Process</strong>, the boundary of the Event is dashed (see the lower figure on the right).</td>
</tr>
<tr>
<td>Signal</td>
<td>If there is only one (1) <strong>EventDefinition</strong> associated with the <strong>Start Event</strong> and that <strong>EventDefinition</strong> is of the subclass SignalEventDefinition, then the <strong>Event</strong> is a <strong>Signal Start Event</strong> and uses an triangle marker (see the figures to the right). For a <strong>Signal Event Sub-Process</strong> that interrupts its containing <strong>Process</strong>, then the boundary of the Event is solid (see the upper figure to the right). For a <strong>Signal Event Sub-Process</strong> that does not interrupt its containing <strong>Process</strong>, the boundary of the <strong>Event</strong> is dashed (see the lower figure on the right).</td>
</tr>
</tbody>
</table>
Attributes for Start Events

For Start Events, the following additional attribute exists:

The Start Event element inherits the attributes and model associations of CatchEvent (see Table 10.82). Table 10.87 presents the additional attributes of the Start Event element:

Table 10.87 – Start Event attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>isInterrupting: boolean = true</td>
<td>This attribute only applies to Start Events of Event Sub-Processes; it is ignored for other Start Events. This attribute denotes whether the Sub-Process encompassing the Event Sub-Process should be cancelled or not. If the encompassing Sub-Process is not cancelled, multiple instances of the Event Sub-Process can run concurrently. This attribute cannot be applied to Error Events (where it’s always true), or Compensation Events (where it doesn’t apply).</td>
</tr>
</tbody>
</table>
Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 41 for the entire set of objects and how they MAY be a source or target of a Sequence Flow.

- A Start Event MUST NOT be a target for Sequence Flows; it MUST NOT have incoming Sequence Flows.
- An exception to this is when a Start Event is used in an Expanded Sub-Process and is attached to the boundary of that Sub-Process. In this case, a Sequence Flow from the higher-level Process MAY connect to that Start Event in lieu of connecting to the actual boundary of the Sub-Process.
- A Start Event MUST be a source for a Sequence Flow.
- Multiple Sequence Flows MAY originate from a Start Event. For each Sequence Flow that has the Start Event as a source, a new parallel path SHALL be generated.
- The conditionExpression attribute for all outgoing Sequence Flows MUST be set to None.
- When a Start Event is not used, then all Flow Objects that do not have an incoming Sequence Flow SHALL be the start of a separate parallel path.
- Each path will have a separate unique token that will traverse the Sequence Flow.

Message Flow Connections

Note – All Message Flows MUST connect two separate Pools. They MAY connect to the Pool boundary or to Flow Objects within the Pool boundary. They MUST NOT connect two objects within the same Pool.

See Section “Message Flow Connection Rules” on page 43 for the entire set of objects and how they MAY be a source or targets of a Message Flow.

- A Start Event MAY be the target for a Message Flow; it can have zero (0) or more incoming Message Flows. Each Message Flow targeting a Start Event represents an instantiation mechanism (a trigger) for the Process. Only one of the triggers is REQUIRED to start a new Process.
- A Start Event MUST NOT be a source for a Message Flow; it MUST NOT have outgoing Message Flows.

10.4.3 End Event

As the name implies, the End Event indicates where a Process will end. In terms of Sequence Flows, the End Event ends the flow of the Process, and thus, will not have any outgoing Sequence Flows—no Sequence Flow can connect from an End Event.

The End Event shares the same basic shape of the Start Event and Intermediate Event, a circle with an open center so that markers can be placed within the circle to indicate variations of the Event.

- An End Event is a circle that MUST be drawn with a single thick line (see Figure 10.71).
- The use of text, color, size, and lines for an End Event MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41 with the exception that:

  The thickness of the line MUST remain thick so that the End Event can be distinguished from the Intermediate and Start Events.
To continue discussing how flow proceeds throughout the Process, an End Event consumes a token that had been generated from a Start Event within the same level of Process. If parallel Sequence Flows target the End Event, then the tokens will be consumed as they arrive. All the tokens that were generated within the Process MUST be consumed by an End Event before the Process has been completed. In other circumstances, if the Process is a Sub-Process, it can be stopped prior to normal completion through interrupting Intermediate Events (See Section 10.2.2, “exception flow,” on page 283 for more details). In this situation the tokens will be consumed by an Intermediate Event attached to the boundary of the Sub-Process.

Semantics of the End Event include:

- There MAY be multiple End Events within a single level of a Process.
- An End Event is OPTIONAL: a given Process level—a Process or an expanded Sub-Process—MAY (is NOT REQUIRED to) have this shape:
  - If an End Event is not used, then the implicit End Event for the Process SHALL NOT have a Result.
  - If there is a Start Event, then there MUST be at least one End Event.
  - If the End Event is not used, then all Flow Objects that do not have any outgoing Sequence Flow (i.e., are not a source of a Sequence Flow) mark the end of a path in the Process. However, the Process MUST NOT end until all parallel paths have completed.

Note – A Process MAY have more than one Process level (i.e., it can include Expanded Sub-Processes or a Call Activity that call other Processes). The use of Start and End Events is independent for each level of the Diagram.

For Processes without an End Event, a token entering a path-ending Flow Object will be consumed when the processing performed by the object is completed (i.e., when the path has completed), as if the token had then gone on to reach an End Event. When all tokens for a given instance of the Process are consumed, then the Process will reach a state of being completed.

End Event Results

There are nine (9) types of End Events in BPMN: None, Message, Escalation, Error, Cancel, Compensation, Signal, Terminate, and Multiple. These types define the consequence of reaching an End Event. This will be referred to as the End Event Result.
### Table 10.88 - End Event Types

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The <strong>None End Event</strong> does not have a defined result. There is no specific EventDefinition subclass (see page 268) for None End Events. If the End Event has no associated EventDefinition, then the Event will be displayed without a marker (see the figure on the right).</td>
<td></td>
</tr>
<tr>
<td>Message</td>
<td>This type of End indicates that a Message is sent to a Participant at the conclusion of the Process. See page 93 for more details on Messages. The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10.1.</td>
<td><img src="email.png" alt="Message" /></td>
</tr>
<tr>
<td>Error</td>
<td>This type of End indicates that a named Error should be generated. All currently active threads in the particular Sub-Process are terminated as a result. The Error will be caught by a Catch Error Intermediate Event with the same errorCode or no errorCode which is on the boundary of the nearest enclosing parent Activity (hierarchically). The behavior of the Process is unspecified if no Activity in the hierarchy has such an Error Intermediate Event. The system executing the process can define additional Error handling in this case, a common one being termination of the Process instance.</td>
<td><img src="warning.png" alt="Error" /></td>
</tr>
<tr>
<td>Escalation</td>
<td>This type of End indicates that an Escalation should be triggered. Other active threads are not affected by this and continue to be executed. The Escalation will be caught by a Catch Escalation Intermediate Event with the same escalationCode or no escalationCode which is on the boundary of the nearest enclosing parent Activity (hierarchically). The behavior of the Process is unspecified if no Activity in the hierarchy has such an Escalation Intermediate Event.</td>
<td><img src="exclamation.png" alt="Escalation" /></td>
</tr>
<tr>
<td>Cancel</td>
<td>This type of End is used within a Transaction Sub-Process. It will indicate that the Transaction should be cancelled and will trigger a Cancel Intermediate Event attached to the Sub-Process boundary. In addition, it will indicate that a TransactionProtocol Cancel Message should be sent to any Entities involved in the Transaction.</td>
<td><img src="cancel.png" alt="Cancel" /></td>
</tr>
</tbody>
</table>
### Table 10.88 - End Event Types

| Compensation | This type of End indicates that compensation is necessary. If an Activity is identified, and it was successfully completed, then that Activity will be compensated. The Activity MUST be visible from the Compensation End Event, i.e., one of the following MUST be true:  
- The Compensation End Event is contained in normal flow at the same level of Sub-Process.  
- The Compensation End Event is contained in a Compensation Event Sub-Process which is contained in the Sub-Process containing the Activity.  
- If no Activity is identified, all successfully completed Activities visible from the Compensation End Event are compensated, in reverse order of their Sequence Flows. Visible means one of the following:  
  - The Compensation End Event is contained in normal flow at the same level of Sub-Process as the Activities.  
  - The Compensation End Event is contained in a Compensation Event Sub-Process which is contained in the Sub-Process containing the Activities.  
To be compensated, an Activity MUST have a boundary Compensation Event or contain a Compensation Event Sub-Process. |
| Signal | This type of End indicates that a Signal will be broadcasted when the End has been reached. Note that the Signal, which is broadcast to any Process that can receive the Signal, can be sent across Process levels or Pools, but is not a Message (which has a specific source and target). The attributes of a Signal can be found on page 281. |
| Terminate | This type of End indicates that all Activities in the Process should be immediately ended. This includes all instances of multi-instances. The Process is ended without compensation or event handling. |
| Multiple | This means that there are multiple consequences of ending the Process. All of them will occur (e.g., there might be multiple Messages sent). There is no specific EventDefinition subclass (see page 268) for Multiple End Events. If the End Event has more than one associated EventDefinition, then the Event will be displayed with the Multiple Event marker (a pentagon—see the figure on the right). |
Sequence Flow Connections

See Section “Sequence Flow Connections Rules” on page 42 for the entire set of objects and how they MAY be a source or target of a Sequence Flow.

◆ An End Event MUST be a target for a Sequence Flow.

◆ An End Event MAY have multiple incoming Sequence Flows.

The Flow MAY come from either alternative or parallel paths. For modeling convenience, each path MAY connect to a separate End Event object. The End Event is used as a Sink for all tokens that arrive at the Event. All tokens that are generated at the Start Event for that Process MUST eventually arrive at an End Event. The Process will be in a running state until all tokens are consumed.

◆ An End Event MUST NOT be a source for Sequence Flows; that is, there MUST NOT be outgoing Sequence Flows.

◆ An exception to this is when an End Event is used in an Expanded Sub-Process and is attached to the boundary of that Sub-Process. In this case, a Sequence Flow from the higher-level Process MAY connect from that End Event in lieu of connecting from the actual boundary of the Sub-Process.

Message Flow Connections

See Section “Message Flow Connection Rules” on page 43 for the entire set of objects and how they MAY be a source or target of a Message Flow.

Note – All Message Flows MUST connect two separate Pools. They MAY connect to the Pool boundary or to Flow Objects within the Pool boundary. They MUST NOT connect two objects within the same Pool.

◆ An End Event MUST NOT be the target of a Message Flow; it can have no incoming Message Flows.

◆ An End Event MAY be the source of a Message Flow; it can have zero (0) or more outgoing Message Flows. Each Message Flow leaving the End Event will have a Message sent when the Event is triggered.

◆ The Result attribute of the End Event MUST be set to Message or Multiple if there are any outgoing Message Flows.

◆ The Result attribute of the End Event MUST be set to Multiple if there is more than one (1) outgoing Message Flows.

10.4.4 Intermediate Event

As the name implies, the Intermediate Event indicates where something happens (an Event) somewhere between the start and end of a Process. It will affect the flow of the Process, but will not start or (directly) terminate the Process. Intermediate Events can be used to:

• Show where Messages are expected or sent within the Process,

• Show delays are expected within the Process,

• Disrupt the normal flow through exception handling, or

• Show the extra work needed for compensation.

The Intermediate Event shares the same basic shape of the Start Event and End Event, a circle with an open center so that markers can be placed within the circle to indicate variations of the Event.
◆ An **Intermediate Event** is a circle that MUST be drawn with a double thin line. (see Figure 10.72).
◆ The use of text, color, size, and lines for an **Intermediate Event** MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41 with the exception that:
◆ The thickness of the line MUST remain double so that the **Intermediate Event** can be distinguished from the **Start** and **End Events**.

Figure 10.72 - Intermediate Event

One use of **Intermediate Events** is to represent exception or **compensation handling**. This will be shown by placing the **Intermediate Event** on the boundary of a **Task** or **Sub-Process** (either collapsed or expanded). The **Intermediate Event** can be attached to any location of the **Activity** boundary and the **outgoing Sequence Flows** can flow in any direction. However, in the interest of clarity of the Diagram, we RECOMMEND that the modeler choose a consistent location on the boundary. For example, if the Diagram orientation is horizontal, then the **Intermediate Events** can be attached to the bottom of the **Activity** and the **Sequence Flows** directed down, then to the right. If the Diagram orientation is vertical, then the **Intermediate Events** can be attached to the left or right side of the **Activity** and the **Sequence Flows** directed to the left or right, then down.

**Intermediate Event Triggers**

There are twelve (12) types of **Intermediate Events** in BPMN: **None**, **Message**, **Timer**, **Escalation**, **Error**, **Cancel**, **Compensation**, **Conditional**, **Link**, **Signal**, **Multiple**, and **Parallel Multiple**. Each type of **Intermediate Event** will have a different icon placed in the center of the **Intermediate Event** shape to distinguish one from another.

There are two (2) ways that **Intermediate Events** are used in BPMN:

An **Intermediate Event** that is placed within the **normal flow** of a **Process** can be used for one of two purposes. The **Event** can respond to (“catch”) the **Event trigger** or the **Event** can be used to set off (“throw”) the **Event trigger**. An **Intermediate Event** that is attached to the boundary of an **Activity** can only be used to “catch” the **Event trigger**.

**Intermediate Events in Normal Flow**

When a **token** arrives at an **Intermediate Event** that is placed within the **normal flow** of a **Process**, one of two things will happen. If the **Event** is used to “throw” the **Event trigger**, then **trigger** of the **Event** will immediately occur (e.g., the **Message** will be sent) and the **token** will move down the **outgoing Sequence Flow**. If the **Event** is used to “catch” the **Event trigger**, then the **token** will remain at the **Event** until the **trigger** occurs (e.g., the **Message** is received). Then the **token** will move down the **outgoing Sequence Flow**.

Ten (10) of the twelve (12) **Intermediate Events** can be used in **normal flow**. Table 10.89
### Table 10.89 – Intermediate Event Types in Normal Flow

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>The <strong>None Intermediate Event</strong> is only valid in <em>normal flow</em>, i.e., it <strong>MAY NOT</strong> be used on the boundary of an <em>Activity</em>. Although there is no specific <em>trigger</em> for this <em>Event</em>, it is defined as &quot;throw Event&quot;. It is used for modeling methodologies that use <em>Events</em> to indicate some change of state in the <em>Process</em>. There is no specific <em>EventDefinition</em> subclass (see page 268) for <em>None Intermediate Events</em>. If the (throw) <em>Intermediate Event</em> has no associated <em>EventDefinition</em>, then the <em>Event</em> <strong>MUST</strong> be displayed without a marker (see the figure on the right).</td>
<td></td>
</tr>
<tr>
<td>Message</td>
<td>A <em>Message Intermediate Event</em> can be used to either send a <em>Message</em> or receive a <em>Message</em>. When used to “throw” the <em>Message</em>, the <em>Event</em> marker <strong>MUST</strong> be filled (see the upper figure on the right). When used to “catch” the <em>Message</em>, then the <em>Event</em> marker <strong>MUST</strong> be unfilled (see the lower figure on the right). This causes the <em>Process</em> to continue if it was waiting for the <em>Message</em>, or changes the flow for <em>exception handling</em>. The actual <em>Participant</em> from which the <em>Message</em> is received can be identified by connecting the <em>Event</em> to a <em>Participant</em> using a <em>Message Flow</em> within the <em>definitional Collaboration</em> of the <em>Process</em> – see Table 10.1. See page 93 for more details on <em>Messages</em>.</td>
<td></td>
</tr>
<tr>
<td>Timer</td>
<td>In <em>normal flow</em> the <em>Timer Intermediate Event</em> acts as a delay mechanism based on a specific time-date or a specific cycle (e.g., every Monday at 9am) can be set that will trigger the <em>Event</em>. This <em>Event</em> <strong>MUST</strong> be displayed with a clock marker (see the figure on the right).</td>
<td></td>
</tr>
<tr>
<td>Escalation</td>
<td>In <em>normal flow</em>, the Escalation <em>Intermediate Event</em> raises an Escalation. Since this is a <em>Throw Event</em>, the arrowhead marker will be filled (see the figure to the right).</td>
<td></td>
</tr>
</tbody>
</table>

<tr>
<td></td>
<td><strong>Compensation</strong>                                                                                           <strong>Conditional</strong></td>
</tr>
<tr>
<td></td>
<td>This type of <strong>Event</strong> is triggered when a condition becomes <strong>true</strong>. A condition is a type of <strong>Expression</strong>. The attributes of an <strong>Expression</strong> can be found page 84.</td>
</tr>
<tr>
<td></td>
<td><strong>Link</strong></td>
</tr>
</tbody>
</table>

**Link Intermediate Events** are only valid in *normal flow*, i.e. they MAY NOT be used on the boundary of an **Activity**. A **Link** is a mechanism for connecting two sections of a **Process**. **Link Events** can be used to create looping situations or to avoid long **Sequence Flow** lines. **Link Event** uses are limited to a single **Process** level (i.e., they cannot link a **parent Process** with a **Sub-Process**). Paired **Intermediate Events** can also be used as “Off-Page Connectors” for printing a **Process** across multiple pages. They can also be used as generic “Go To” objects within the **Process** level. There can be multiple **source Link Events**, but there can only be one **target Link Event**. When used to “throw” to the **target Link**, the **Event** marker will be filled (see the top figure on the right). When used to “catch” from the **source Link**, the **Event** marker will be unfilled (see the bottom figure on the right).
Signal This type of Event is used for sending or receiving Signals. A Signal is for general communication within and across Process levels, across Pools, and between Business Process Diagrams. A BPMN Signal is similar to a signal flare that shot into the sky for anyone who might be interested to notice and then react. Thus, there is a source of the Signal, but no specific intended target. This type of Intermediate Event can send or receive a Signal if the Event is part of a normal flow. The Event can only receive a Signal when attached to the boundary of an Activity. The Signal Event differs from an Error Event in that the Signal defines a more general, non-error condition for interrupting Activities (such as the successful completion of another Activity) as well as having a larger scope than Error Events. When used to “catch” the Signal, the Event marker will be unfilled (see the middle figure on the right). When used to “throw” the Signal, the Event marker will be filled (see the top figure on the right). The attributes of a Signal can be found on page 281.

Multiple This means that there are multiple triggers assigned to the Event. If used within normal flow, the Event can “catch” the trigger or “throw” the triggers. When attached to the boundary of an Activity, the Event can only “catch” the trigger. When used to “catch” the trigger, only one of the assigned triggers is REQUIRED and the Event marker will be unfilled (see the middle figure on the right). When used to “throw” the trigger (the same as a Multiple End Event), all the assigned triggers will be thrown and the Event marker will be filled (see the top figure on the right). There is no specific EventDefinition subclass (see page 268) for Multiple Intermediate Events. If the Intermediate Event has more than one associated EventDefinition, then the Event will be displayed with the Multiple Event marker.

Parallel Multiple This means that there are multiple triggers assigned to the Event. If used within normal flow, the Event can only “catch” the trigger. When attached to the boundary of an Activity, the Event can only “catch” the trigger. Unlike the normal Multiple Intermediate Event, all of the assigned triggers are REQUIRED for the Event to be triggered. The Event marker will be an unfilled plus sign (see the figure on the right). There is no specific EventDefinition subclass (see page 268) for Parallel Multiple Intermediate Events. If the Intermediate Event has more than one associated EventDefinition and the parallelMultiple attribute of the Intermediate Event is true, then the Event will be displayed with the Parallel Multiple Event marker.
### Intermediate Events Attached to an Activity Boundary

Table 10.90 describes the Intermediate Events that can be attached to the boundary of an Activity.

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
<th>Marker</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Message</strong></td>
<td>A Message arrives from a participant and triggers the Event. If a Message Event is attached to the boundary of an Activity, it will change the normal flow into an exception flow upon being triggered. For a Message Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to true. For a Message Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to false. The actual Participant from which the Message is received can be identified by connecting the Event to a Participant using a Message Flow within the definitional Collaboration of the Process – see Table 10.1.</td>
<td><strong>Interrupting</strong></td>
</tr>
<tr>
<td><strong>Timer</strong></td>
<td>A specific time-date or a specific cycle (e.g., every Monday at 9am) can be set that will trigger the Event. If a Timer Event is attached to the boundary of an Activity, it will change the normal flow into an exception flow upon being triggered. For a Timer Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to true. For a Timer Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to false.</td>
<td><strong>Interrupting</strong></td>
</tr>
</tbody>
</table>
Escalation | This type of Event is used for handling a named Escalation. If attached to the boundary of an Activity, the Intermediate Event catches an Escalation. In contrast to an Error, an Escalation by default is assumed to not abort the Activity to which the boundary Event is attached. However, a modeler can decide to override this setting by using the notation described in the following.

For an Escalation Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to true.

For an Escalation Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to false.

Error | A catch Intermediate Error Event can only be attached to the boundary of an Activity, i.e., it MAY NOT be used in normal flow. If used in this context, it reacts to (catches) a named Error, or to any Error if a name is not specified.

Note that an Error Event always interrupts the Activity to which it is attached, i.e., there is not a non-interrupting version of this Event. The boundary of the Event thus always solid (see figure on the right).

Cancel | This type of Intermediate Event is used within a Transaction Sub-Process. This type of Event MUST be attached to the boundary of a Sub-Process. It SHALL be triggered if a Cancel End Event is reached within the Transaction Sub-Process. It also SHALL be triggered if a TransactionProtocol “Cancel” Message has been received while the transaction is being performed.

Note that a Cancel Event always interrupts the Activity to which it is attached, i.e., there is not a non-interrupting version of this Event. The boundary of the Event thus always solid (see figure on the right).

Compensation | When attached to the boundary of an Activity, this Event is used to "catch" the Compensation Event, thus the Event marker MUST be unfilled (see figure on the right). The Event will be triggered by a thrown compensation targeting that Activity. When the Event is triggered, the Compensation Activity that is associated to the Event will be performed (see page 311).

Note that the interrupting a non-interrupting aspect of other Events does not apply in the case of a Compensation Event. Compensations can only be triggered after completion of the Activity to which they are attached. Thus they cannot interrupt the Activity. The boundary of the Event is always solid.
### Table 10.90 – Intermediate Event Types Attached to an Activity Boundary

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>PX</th>
<th>Non-Interrupting</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Conditional</strong></td>
<td>This type of Event is triggered when a condition becomes true. A condition is a type of Expression. The attributes of an Expression can be found on page 84. If a Conditional Event is attached to the boundary of an Activity, it will change the normal flow into an exception flow upon being triggered. For a Conditional Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to true. For a Conditional Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to false.</td>
<td>Interrupting</td>
<td></td>
</tr>
<tr>
<td><strong>Signal</strong></td>
<td>The Signal Event can receive a Signal when attached to the boundary of an Activity. In this context, it will change the normal flow into an exception flow upon being triggered. The Signal Event differs from an Error Event in that the Signal defines a more general, non-error condition for interrupting Activities (such as the successful completion of another Activity) as well as having a larger scope than Error Events. When used to “catch” the Signal, the Event marker will be unfilled. The attributes of a Signal can be found on page 281. For a Signal Event that interrupts the Activity to which it is attached, the boundary of the Event is solid (see upper figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to true. For a Signal Event that does not interrupt the Activity to which it is attached, the boundary of the Event is dashed (see lower figure on the right). Note that if using this notation, the attribute cancelActivity of the Activity to which the Event is attached is implicitly set to false.</td>
<td>Interrupting</td>
<td></td>
</tr>
</tbody>
</table>
A **Multiple Event** indicates that there are multiple *triggers* assigned to the **Event**. When attached to the boundary of an **Activity**, the **Event** can only "catch" the *trigger*. In this case, only one of the assigned *triggers* is REQUIRED and the **Event** marker will be unfilled upon being triggered, the **Event** that occurred will change the *normal flow* into an *exception flow*.

There is no specific **EventDefinition** subclass (see page 268) for **Multiple Intermediate Events**. If the **Intermediate Event** has more than one associated **EventDefinition**, then the **Event** will be displayed with the **Multiple Event** marker.

For a **Multiple Event** that interrupts the **Activity** to which it is attached, the boundary of the **Event** is solid (see upper figure on the right). Note that if using this notation, the attribute **cancelActivity** of the **Activity** to which the **Event** is attached is implicitly set to *true*.

For a **Multiple Event** that does not interrupt the **Activity** to which it is attached, the boundary of the **Event** is dashed (see lower figure on the right). Note that if using this notation, the attribute **cancelActivity** of the **Activity** to which the **Event** is attached is implicitly set to *false*.

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>Diagram</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiple</td>
<td>A <strong>Multiple Event</strong> indicates that there are multiple <em>triggers</em> assigned to the <strong>Event</strong>. When attached to the boundary of an <strong>Activity</strong>, the <strong>Event</strong> can only &quot;catch&quot; the <em>trigger</em>. In this case, only one of the assigned <em>triggers</em> is REQUIRED and the <strong>Event</strong> marker will be unfilled upon being triggered, the <strong>Event</strong> that occurred will change the <em>normal flow</em> into an <em>exception flow</em>. There is no specific <strong>EventDefinition</strong> subclass (see page 268) for <strong>Multiple Intermediate Events</strong>. If the <strong>Intermediate Event</strong> has more than one associated <strong>EventDefinition</strong>, then the <strong>Event</strong> will be displayed with the <strong>Multiple Event</strong> marker. For a <strong>Multiple Event</strong> that interrupts the <strong>Activity</strong> to which it is attached, the boundary of the <strong>Event</strong> is solid (see upper figure on the right). Note that if using this notation, the attribute <strong>cancelActivity</strong> of the <strong>Activity</strong> to which the <strong>Event</strong> is attached is implicitly set to <em>true</em>. For a <strong>Multiple Event</strong> that does not interrupt the <strong>Activity</strong> to which it is attached, the boundary of the <strong>Event</strong> is dashed (see lower figure on the right). Note that if using this notation, the attribute <strong>cancelActivity</strong> of the <strong>Activity</strong> to which the <strong>Event</strong> is attached is implicitly set to <em>false</em>.</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
<tr>
<td>Parallel Multiple</td>
<td>This means that there are multiple <em>triggers</em> assigned to the <strong>Event</strong>. When attached to the boundary of an <strong>Activity</strong>, the <strong>Event</strong> can only &quot;catch&quot; the <em>trigger</em>. Unlike the normal <strong>Multiple Intermediate Event</strong>, all of the assigned <em>triggers</em> are REQUIRED for the <strong>Event</strong> to be triggered. The <strong>Event</strong> marker will be an unfilled plus sign (see the figures on the right). There is no specific <strong>EventDefinition</strong> subclass (see page 268) for <strong>Parallel Multiple Intermediate Events</strong>. If the <strong>Intermediate Event</strong> has more than one associated <strong>EventDefinition</strong> and the <strong>parallelMultiple</strong> attribute of the <strong>Intermediate Event</strong> is <em>true</em>, then the <strong>Event</strong> will be displayed with the <strong>Parallel Multiple Event</strong> marker. For a <strong>Parallel Multiple Event</strong> that interrupts the <strong>Activity</strong> to which it is attached, the boundary of the <strong>Event</strong> is solid (see the upper figure to the right). Note that if using this notation, the attribute <strong>cancelActivity</strong> of the <strong>Activity</strong> to which the <strong>Event</strong> is attached is implicitly set to <em>true</em>. For a <strong>Parallel Multiple Event</strong> that does not interrupt the <strong>Activity</strong> to which it is attached, the boundary of the <strong>Event</strong> is dashed (see the lower figure to the right). Note that if using this notation, the attribute <strong>cancelActivity</strong> of the <strong>Activity</strong> to which the <strong>Event</strong> is attached is implicitly set to <em>false</em>.</td>
<td><img src="image" alt="Diagram" /></td>
</tr>
</tbody>
</table>
Attributes for Boundary Events

For boundary Events, the following additional attributes exists:

The BoundaryEvent element inherits the attributes and model associations of CatchEvent (see Table 8.44). Table 8.46 presents the additional attributes and model associations of the Boundary Event element:

Table 10.91 – Boundary Event attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>attachedTo: Activity</td>
<td>Denotes the Activity that boundary Event is attached to.</td>
</tr>
<tr>
<td>cancelActivity: boolean</td>
<td>Denotes whether the Activity should be cancelled or not, i.e., whether the boundary catch Event acts as an Error or an Escalation. If the Activity is not cancelled, multiple instances of that handler can run concurrently. This attribute cannot be applied to Error Events (where it’s always true), or Compensation Events (where it doesn’t apply).</td>
</tr>
</tbody>
</table>

Table 10.92 specifies whether the cancel Activity attribute can be set on a boundary Event depending on the EventDefinition it catches.

Table 10.92 – Possible Values of the cancelActivity Attribute

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Possible Values for the cancelActivity Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>N/A as this event cannot be attached to the Activity border.</td>
</tr>
<tr>
<td>Message</td>
<td>True/false</td>
</tr>
<tr>
<td>Timer</td>
<td>True/false</td>
</tr>
<tr>
<td>Escalation</td>
<td>True/false</td>
</tr>
<tr>
<td>Error</td>
<td>True</td>
</tr>
<tr>
<td>Cancel</td>
<td>True</td>
</tr>
<tr>
<td>Compensation</td>
<td>N/A as the scope was already executed and can no longer be canceled when compensation is triggered.</td>
</tr>
<tr>
<td>Conditional</td>

</tr>
<tr>
<td>Signal</td>
<td>True/false</td>
</tr>
<tr>
<td>Multiple</td>
<td>True/false if all Event triggers allow this option (see this table for details). Otherwise the more restrictive option, i.e. Yes in case any Error or cancel triggers are used.</td>
</tr>
</tbody>
</table>

Activity Boundary Connections

An Intermediate Event can be attached to the boundary of an Activity under the following conditions:
(One or more) **Intermediate Events** MAY be attached directly to the boundary of an **Activity**.

To be attached to the boundary of an **Activity**, an **Intermediate Event** MUST be one of the following **triggers** (EventDefinition): Message, Timer, Error, Escalation, Cancel, Compensation, Conditional, Signal, Multiple, and Parallel Multiple.

**An Intermediate Event** with a **Cancel** trigger MAY be attached to a **Sub-Process** boundary only if the Transaction attribute of the **Sub-Process** is set to **true**.

**Sequence Flow Connections**

See Section “Sequence Flow Connections Rules” on page 42 for the entire set of objects and how they MAY be a **source** or **target** of a **Sequence Flow**.

If the **Intermediate Event** is attached to the boundary of an **Activity**:

- The **Intermediate Event** MUST NOT be a target for a **Sequence Flow**; it cannot have an **incoming** **Sequence Flows**.
- The **Intermediate Event** MUST be a source for a **Sequence Flow**.
- Multiple **Sequence Flows** MAY originate from an **Intermediate Event**. For each **Sequence Flow** that has the **Intermediate Event** as a source, a new parallel path SHALL be generated.
  - An exception to this: an **Intermediate Event** with a Compensation **trigger** MUST NOT have an **outgoing** **Sequence Flow** (it MAY have an **outgoing** **Association**).

**The Intermediate Events** with the following **triggers** (EventDefinition) MAY be used in **normal flow**: None, Message, Timer, Escalation, Compensation, Conditional, Link, Signal, Multiple, and ParallelMultiple. Thus, the following MUST NOT: Cancel and Error.

If the **Intermediate Event** is used within **normal flow**:

- **Intermediate Events** MUST be a target of a **Sequence Flow**.

**Note** – this is a change from **BPMN 1.2** semantics, which allowed some **Intermediate Events** to not have an **incoming** **Sequence Flow**.

- **An Intermediate Event** MAY have multiple **incoming** **Sequence Flows**.

**Note** – If the **Event** has multiple **incoming Sequence Flows**, then this is considered **uncontrolled flow**. This means that when a **token** arrives from one of the Paths, the **Event** will be enabled (to **catch** or **throw**). It will not wait for the arrival of **tokens** from the other paths. If another **token** arrives from the same path or another path, then a separate **instance** of the **Event** will be created. If the flow needs to be controlled, then the flow should converge with a **Gateway** that precedes the **Event** (see page 295 for more information on **Gateways**).

- **An Intermediate Event** MUST be a source for a **Sequence Flow**.
- Multiple **Sequence Flows** MAY originate from an **Intermediate Event**. For each **Sequence Flow** that has the **Intermediate Event** as a source, a new parallel path SHALL be generated.
  - An exception to this: a **source** **Link Intermediate Event** (as defined below), it is NOT REQUIRED to have an **outgoing** **Sequence Flow**.
- **A Link Intermediate Event** MUST NOT be both a **target** and a **source** of a **Sequence Flow**.

To define the use of a **Link Intermediate Event** as an “Off-Page Connector” or a “Go To” object:

- **A Link Intermediate Event** MAY be the target (**target Link**) or a source (**source Link**) of a **Sequence Flow**,
but MUST NOT be both a\textit{ target} and a\textit{ source}.

\begin{itemize}
  \item If there is a \textit{source} \text{Link}, there MUST be a matching \textit{target} \text{Link} (they have the same \text{name}).
  \item There MAY be multiple \textit{source} \text{Links} for a single \textit{target} \text{Link}.
  \item There MUST NOT be multiple \textit{target} \text{Links} for a single \textit{source} \text{Link}.
\end{itemize}

\section*{Message Flow Connections}

See Section “Message Flow Connection Rules” on page 42 for the entire set of objects and how they MAY be a \textit{source} or \textit{target} of a \textit{Message Flow}.

\textbf{Note –} All \textbf{Message Flows} MUST connect two separate \textbf{Pools}. They MAY connect to the \textbf{Pool} boundary or to Flow Objects within the \textbf{Pool} boundary. They MUST NOT connect two objects within the same \textbf{Pool}.

\begin{itemize}
  \item A \textbf{Message Intermediate Event} MAY be the \textit{target} for a \textbf{Message Flow}; it can have one (1) \textit{incoming} \text{Message Flow}.
  \item A \textbf{Message Intermediate Event} MAY be a \textit{source} for a \textbf{Message Flow}; it can have one (1) \textit{outgoing} \text{Message Flow}.
  \item A \textbf{Message Intermediate Event} MAY have an \textit{incoming} \text{Message Flow} or an \textit{outgoing} \text{Message Flow}, but not both.
\end{itemize}

\section*{10.4.5 Event Definitions}

\textit{Event Definitions} refers to the \textit{triggers} of \textbf{Catch Events} (\textit{Start} and \textit{receive} \textbf{Intermediate Events}) and the Results of \textbf{Throw Events} (\textit{End Events} and \textit{send} \textbf{Intermediate Events}). The types of \textbf{Event} Definitions are: \textbf{CancelEventDefinition}, \textbf{CompensationEventDefinition}, \textbf{ConditionalEventDefinition}, \textbf{ErrorEventDefinition}, \textbf{EscalationEventDefinition}, \textbf{MessageEventDefinition}, \textbf{LinkEventDefinition}, \textbf{SignalEventDefinition}, \textbf{TerminateEventDefinition}, and \textbf{TimerEventDefinition} (see Table 10.93). A \textbf{None Event} is determined by an \textbf{Event} that does not specify an \textbf{Event} Definition. A \textbf{Multiple Event} is determined by an \textbf{Event} that specifies more than one \textbf{Event} Definition. The different types of \textbf{Events} (\textit{Start}, \textit{End}, and \textit{Intermediate}) utilize a subset of the available types of \textbf{Event} Definitions.

</table>
The following sections will present the attributes common to all Event Definitions and the specific attributes for the Event Definitions that have additional attributes. Note that the Cancel and Terminate Event Definitions do not have additional attributes.

### Event Definition Metamodel

Figure 10.73 shows the class diagram for the abstract class EventDefinition. When one of the EventDefinition sub-types (e.g., TimerEventDefinition) is defined it is contained in Definitions, or a contained EventDefinition contained in a throw/catch Event.

<table>
<thead>

<td><img src="blank.png" alt="Blank" /></td>
<td><img src="blank.png" alt="Blank" /></td>
<td><img src="blank.png" alt="Blank" /></td>
</tr>
</tbody>
</table>

The following sections will present the sub-types of EventDefinitions.
Cancel Event

Cancel Events are only used in the context of modeling Transaction Sub-Processes (see page 184 for more details on Transactions). There are two (2) variations: a catch Intermediate Event and an End Event.

- The catch Cancel Intermediate Event MUST only be attached to the boundary of a Transaction Sub-Process and, thus, MAY NOT be used in normal flow.
- The Cancel End Event MUST only be used within a Transaction Sub-Process and, thus, MAY NOT be used in any other type of Sub-Process or Process.

Figure 10.74 shows the variations of Cancel Events.

![Cancel Events](image)

Compensation Event

Compensation Events are used in the context of triggering or handling compensation (see page 311 for more details on compensation). There are four (4) variations: a Start Event, both a catch and throw Intermediate Event, and an End Event.

- The Compensation Start Event MAY NOT be used for a top-level Process.
- The Compensation Start Event MAY be used for an Event Sub-Process.
- The catch Compensation Intermediate Event MUST only be attached to the boundary of an Activity and, thus, MAY NOT be used in normal flow.
- The throw Compensation Intermediate Event MAY be used in normal flow.
- The Compensation End Event MAY be used within any Sub-Process or Process.

Figure 10.75 shows the variations of Compensation Events.

![Compensation Events](image)

Figure 10.76 displays the class diagram for the CompensationEventDefinition.
The CompensationEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to the EventDefinition element (see page 268). Table 10.94 presents the additional attributes and model associations of the CompensationEventDefinition element:

**Table 10.94 – CompensationEventDefinition attributes and model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
</table>
| **activityRef**: Activity [0..1] | For a **Start Event**:  
  This Event "catches" the compensation for an Event Sub-Process. No further information is REQUIRED. The Event Sub-Process will provide the Id necessary to match the Compensation Event with the Event that threw the compensation, or the compensation will have been a broadcast.  
  For an **End Event**:  
  The Activity to be compensated MAY be supplied. If an Activity is not supplied, then the compensation is broadcast to all completed Activities in the current Sub-Process (if present), or the entire Process instance (if at the global level).  
  For an **Intermediate Event** within normal flow:  
  The Activity to be compensated MAY be supplied. If an Activity is not supplied, then the compensation is broadcast to all completed Activities in the current Sub-Process (if present), or the entire Process instance (if at the global level). This "throws" the compensation.  
  For an **Intermediate Event** attached to the boundary of an Activity:  
  This Event "catches" the compensation. No further information is REQUIRED. The Activity the Event is attached to will provide the Id necessary to match the Compensation Event with the Event that threw the compensation, or the compensation will have been a broadcast. |
| **waitForCompletion**: boolean = true | For a **throw Compensation Event**, this flag determines whether the **throw Intermediate Event** waits for the triggered compensation to complete (the default), or just triggers the compensation and immediately continues (the BPMN 1.2 behavior). |
Conditional Event

Figure 10.77 shows the variations of **Conditional Events**.

![Conditional Event Diagram](image)

**Figure 10.77 – Conditional Events**

The `ConditionalEventDefinition` element inherits the attributes and model associations of `BaseElement` (see Table 8.5) through its relationship to the `EventDefinition` element (see page 268). Table 10.95 presents the additional model associations of the `ConditionalEventDefinition` element:

Figure 10.78 displays the class diagram for the `ConditionalEventDefinition`.

![ConditionalEventDefinition Class Diagram](image)

**Figure 10.78 - ConditionalEventDefinition Class Diagram**

The `ConditionalEventDefinition` element inherits the attributes and model associations of `BaseElement` (see Table 8.5) through its relationship to the `EventDefinition` element (see page 268). Table 10.95 presents the additional model associations of the `ConditionalEventDefinition` element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>condition: Expression</code></td>
<td>The Expression might be underspecified and provided in the form of natural language. For executable Processes (<code>isExecutable = true</code>), if the trigger is Conditional, then a FormalExpression MUST be entered.</td>
</tr>
</tbody>
</table>

Error Event

Figure 10.79 shows the variations of **Conditional Events**.

![Error Event Diagram](image)

**Figure 10.79 – Error Events**
Figure 10.80 displays the class diagram for the *ErrorEventDefinition*.

![ErrorEventDefinition Class Diagram](image)

**Figure 10.80 - ErrorEventDefinition Class Diagram**

The *ErrorEventDefinition* element inherits the attributes and model associations of *BaseElement* (see Table 8.5) through its relationship to the *EventDefinition* element (see page 268). Table 10.96 presents the additional attributes and model associations of the *ErrorEventDefinition* element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>error: Error [0..1]</td>
<td>If the trigger is an Error, then an Error payload MAY be provided.</td>
</tr>
</tbody>
</table>

**Escalation Event Definition**

Figure 10.81 shows the variations of *Escalation Events*.

![Escalation Events](image)

**Figure 10.81 – Escalation Events**

Figure 10.82 displays the class diagram for the *EscalationEventDefinition*. 
The EscalationEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to the EventDefinition element (see page 268). Table 10.97 presents the additional attributes and model associations of the EscalationEventDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>escalationRef: Escalation [0..1]</td>
<td>If the trigger is an Escalation, then an Escalation payload MAY be provided.</td>
</tr>
</tbody>
</table>

**Link Event Definition**

A Link Event is a mechanism for connecting two sections of a Process. Link Events can be used to create looping situations or to avoid long Sequence Flow lines. The use of Link Events is limited to a single Process level (i.e., they cannot link a parent Process with a Sub-Process).

Figure 10.83 shows the variations of Link Events.

Paired Link Events can also be used as “Off-Page Connectors” for printing a Process across multiple pages. They can also be used as generic “Go To” objects within the Process level. There can be multiple source Link Events, but there can only be one target Link Event. When used to “catch” from the source Link, the Event marker will be unfilled (see Figure 10.84: upper right). When used to “throw” to the target Link, the Event marker will be filled (see Figure 10.84: upper: lower Left).
Since Process models often extend beyond the length of one printed page, there is often a concern about showing how Sequence Flow connections extend across the page breaks. One solution that is often employed is the use of Off-Page connectors to show where one page leaves off and the other begins. BPMN provides Intermediate Events of type Link for use as Off-Page connectors (see Figure 10.84—Note that the figure shows two different printed pages, not two Pools in one diagram). A pair of Link Events is used. One of the pair is shown at the end of one page. This Event is named and has an incoming Sequence Flow and no outgoing Sequence Flows. The second Link Event is at the beginning of the next page, shares the same name, and has an outgoing Sequence Flow and no incoming Sequence Flow.

![Figure 10.84 - Link Events Used as Off-Page Connector](image)

Another way that Link Events can be used is as “Go To” objects. Functionally, they would work the same as for Off-Page Connectors (described above), except that they could be used anywhere in the diagram—on the same page or across multiple pages. The general idea is that they provide a mechanism for reducing the length of Sequence Flow lines. Some modelers can consider long lines as being hard to follow or trace. Go To Objects can be used to avoid very long
**Sequence Flows** (see Figure 10.85 and Figure 10.86). Both diagrams will behave equivalently. For Figure 10.86, if the “Order Rejected” path is taken from the Decision, then the *token* traversing the **Sequence Flow** would reach the *source Link Event* and then “jump” to the *target Link Event* and continue down the **Sequence Flow**. The **Process** would continue as if the **Sequence Flow** had directly connected the two objects.

![Figure 10.85 - A Process with a long Sequence Flow](image)

![Figure 10.86 - A Process with Link Intermediate Events used as Go To Objects](image)

Some methodologies prefer that all **Sequence Flows** only move in one direction; that is, forward in time. These methodologies do not allow **Sequence Flows** to connect directly to upstream objects. Some consistency in modeling can be gained by such a methodology, but situations that require looping become a challenge. **Link Events** can be used to make upstream connections and create *loops* without violating the **Sequence Flow** direction restriction (see Figure 10.87).
The `LinkEventDefinition` element inherits the attributes and model associations of `BaseElement` (see Table 8.5) through its relationship to the `EventDefinition` element (see page 268). Table 10.98 presents the additional attributes of the `LinkEventDefinition` element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string</td>
<td>If the <code>trigger</code> is a <code>Link</code>, then the <code>name</code> MUST be entered.</td>
</tr>
<tr>
<td>sources: LinkEventDefinition [1..*]</td>
<td>Used to reference the corresponding 'catch' or 'target' LinkEventDefinition, when this LinkEventDefinition represents a 'throw' or 'source' LinkEventDefinition.</td>
</tr>
<tr>
<td>target: LinkEventDefinition [1]</td>
<td>Used to reference the corresponding 'throw' or 'source' LinkEventDefinition, when this LinkEventDefinition represents a 'catch' or 'target' LinkEventDefinition.</td>
</tr>
</tbody>
</table>

**Message Event Definition**

Figure 10.88 shows the variations of **Message Events**.
Figure 10.89 displays the class diagram for the MessageEventDefinition.

![MessageEventDefinition Class Diagram](image)

The MessageEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to the EventDefinition element (see page 268). Table 10.99 presents the additional model associations of the MessageEventDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageRef: Message</td>
<td>The Message MUST be supplied (if the isExecutable attribute of the Process is set to true).</td>
</tr>
<tr>
<td>operationRef: Operation</td>
<td>This attribute specifies the Operation that is used by the Message Event. It MUST be specified for executable Processes.</td>
</tr>
</tbody>
</table>

Multiple Event

For a Start Event:

If the trigger is Multiple, there are multiple ways of starting the Process. Only one of them is necessary to trigger the start of the Process. The EventDefinition subclasses will define which triggers apply.

For an End Event:

If the Result is Multiple, there are multiple consequences of ending the Process. All of them will occur. The EventDefinition subclasses will define which Results apply.

For an Intermediate Event within normal flow:

If the trigger is Multiple, only one EventDefinition is REQUIRED to catch the trigger. When used to throw, all of the EventDefinitions are considered and the subclasses will define which Results apply.

For an Intermediate Event attached to the boundary of an Activity:
If the trigger is Multiple, only one EventDefinition is REQUIRED to "catch" the trigger.

Figure 10.90 shows the variations of **Multiple Events**.

![Figure 10.90 – Multiple Events](image)

**None Event**

None Events are Events that do not have a defined EventDefinition. There are three (3) variations of None Events: a **Start Event**, a catch **Intermediate Event**, and an **End Event** (see Figure 10.91).

- The **None Start Event** MAY be used for a top-level Process or any type of Sub-Process (except an Event Sub-Process).
- The **None Start Event** MAY NOT be used for an Event Sub-Process.
- The catch **None Intermediate Event** MUST only be used in normal flow and, thus, MAY NOT be attached to the boundary of an Activity.
- The **None End Event** MAY be used within any Sub-Process or Process.

Figure 10.91 shows the variations of **None Events**.

![Figure 10.91 – None Events](image)

**Parallel Multiple Event**

For a **Start Event**:

If the trigger is Multiple, there are multiple triggers REQUIRED to start the Process. All of them are necessary to trigger the start of the Process. The EventDefinition subclasses will define which triggers apply. In addition, the parallelMultiple attribute of the Start Event MUST be set to true.

For an **Intermediate Event** within normal flow:

If the trigger is Multiple, all of the defined EventDefinitions are REQUIRED to trigger the Event. In addition, the parallelMultiple attribute of the Intermediate Event MUST be set to true.

For an **Intermediate Event** attached to the boundary of an Activity:

If the trigger is Multiple, all of the defined EventDefinitions are REQUIRED to trigger the Event. In addition, the parallelMultiple attribute of the Intermediate Event MUST be set to true.

Figure 10.92 shows the variations of **Parallel Multiple Events**.
Signal Event

Figure 10.93 - SignalEventDefinition Class Diagram

Figure 10.94 shows the variations of **Signal Events**.

The **SignalEventDefinition** element inherits the attributes and model associations of **BaseElement** (see Table 8.5) through its relationship to the **EventDefinition** element (see page 268). Table 10.100 presents the additional model associations of the **ConditionalSignalDefinition** element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>signalRef: Signal [0..1]</td>
<td>If the <em>trigger</em> is a <em>Signal</em>, then a <em>Signal</em> is provided.</td>
</tr>
</tbody>
</table>

**Terminate Event**

Figure 10.95 shows the **Terminate Event**.
The TerminateEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to the EventDefinition element (see page 268).

**Timer Event**

Figure 10.96 shows the variations of Timer Events.

The TimerEventDefinition element inherits the attributes and model associations of BaseElement (see Table 8.5) through its relationship to the EventDefinition element (see page 268). Table 10.101 presents the additional model associations of the TimerEventDefinition element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeDate: Expression [0..1]</td>
<td>If the trigger is a Timer, then a timeDate MAY be entered. Timer attributes are mutually exclusive and if any of the other Timer attributes is set, timeDate MUST NOT be set (if the isExecutable attribute of the Process is set to true). The return type of the attribute timeDate MUST conform to the ISO-8601 format for date and time representations.</td>
</tr>
<tr>
<td>timeCycle: Expression [0..1]</td>
<td>If the trigger is a Timer, then a timeCycle MAY be entered. Timer attributes are mutually exclusive and if any of the other Timer attributes is set, timeCycle MUST NOT be set (if the isExecutable attribute of the Process is set to true). The return type of the attribute timeCycle MUST conform to the ISO-8601 format for recurring time interval representations.</td>
</tr>
<tr>
<td>timeDuration: Expression [0..1]</td>
<td>If the trigger is a Timer, then a timeDuration MAY be entered. Timer attributes are mutually exclusive and if any of the other Timer attributes is set, timeDuration MUST NOT be set (if the isExecutable attribute of the Process is set to true). The return type of the attribute timeDuration MUST conform to the ISO-8601 format for time interval representations.</td>
</tr>
</tbody>
</table>
10.4.6 Handling Events

BPMN provides advanced constructs for dealing with Events that occur during the execution of a Process (i.e., the “catching” of an Event). Furthermore, BPMN supports the explicit creation of an Event in the Process (i.e., the “throwing” of an Event). Both catching and throwing of an Event as well as the resulting Process behavior is referred to as Event handling. There are three (3) types of Event handlers: those that start a Process, those that are part of the normal Sequence Flow, and those that are attached to Activities, either via boundary Events or via separate inline handlers in case of an Event Sub-Process.

Handling Start Events

There are multiple ways in which a Process can be started. For single Start Events, handling consists of starting a new Process instance each time the Event occurs. Sequence Flows leaving the Event are then followed as usual. For multiple Start Events, BPMN supports several modeling scenarios that can be applied depending on the scenario.

Exclusive start: the most common scenario for starting a Process is its instantiation by exactly one out of many possible Start Events. Each occurrence of one of these Events will lead to the creation of a new Process instance. The following example shows two Events connected to a single Activity (see Figure 10.97). At runtime, each occurrence of one of the Events will lead to the creation of a new instance of the Process instance and activation of the Activity. Note that a single Multiple Start Event that contains the Message Event Definitions would behave in the same way.

A Process can also be started via an Event-Based Gateway, as in the following example (Figure 10.98):
In that case, the first matching Event will create a new instance of the Process, and waiting for the other Events originating from the same decision stops, following the usual semantics of the Event-Based Exclusive Gateway. Note that this is the only scenario where a Gateway can exist without an incoming Sequence Flows.

It is possible to have multiple groups of Event-Based Gateways starting a Process, provided they participate in the same Conversation and hence share the same correlation information. In that case, one Event out of each group needs to arrive; the first one creates a new Process instance, while the subsequent ones are routed to the existing instance, which is identified through its correlation information.

**Event synchronization:** if the modeler requires several disjoint Start Events to be merged into a single Process instance, then the following notation MUST be applied (Figure 10.99):

The Parallel Start Event MAY group several disjoint Start Events each of which MUST occur once in order for an instance of the Process to be created. Sequence Flows leaving the Event are then followed as usual.

See page 455 for the execution semantics for the Event Handling of Start Events.

**Handling Events within normal Sequence Flow (Intermediate Events)**

For Intermediate Events, the handling consists of waiting for the Event to occur. Waiting starts when the Intermediate Event is reached. Once the Event occurs, it is consumed. Sequence flows leaving the Event are followed as usual.
Handling Events attached to an Activity (Intermediate boundary Events and Event Sub-Processes)

For boundary Events, handling consists of consuming the Event occurrence and either canceling the Activity the Event is attached to, followed by normal Sequence Flows leaving that Activity, or by running an Event Handler without canceling the Activity (only for Message, Signal, Timer and Conditional Events, not for Error Events).

An interrupting boundary Event is defined by a true value of its cancelActivity attribute. Whenever the Event occurs, the associated Activity is terminated. A downstream token is then generated, which activates the next element of the Process (connected to the Event by an unconditional Sequence Flow called an exception flow).

For non-interrupting boundary Events, the cancelActivity attribute is set to false. Whenever the Event occurs, the associated Activity continues to be active. As a token is generated for the Sequence Flow from the boundary Event in parallel to the continuing execution of the Activity, care MUST be taken when this flow is merged into the main flow of the Process – typically it should be ended with its own End Event.

The following example shows a fragment (see Figure 10.100) from a trip booking Process. It contains a Sub-Process that consists of a main part, and three Event Sub-Processes to deal with Events within the same context: an error Event Sub-Process that cancels the Sub-Process, a Message Event Sub-Process that updates the state of the Sub-Process while allowing it to continue, and a Compensation Event Sub-Process.
The following example (see Figure 10.101) shows the same fragment of that Process, using boundary Event handlers rather than inline Event Sub-Processes. Note that in this example, the handlers do not have access to the context of the “Booking” Sub-Process, as they run outside of it. Therefore, the actually compensation logic is shown as a black box.
Figure 10.101 - Example of boundary Event Handling

Note that there is a distinction between interrupting and non-interrupting Events and the handling of these Events, which is described in the sections below. For an interrupting Event (Error, Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple), only one Event Sub-Process for the same Event Declaration MUST be modeled. This excludes any further non-interrupting handlers for that Event Declaration.

The reason for this restriction lies in the nature of interrupting Event Sub-Processes and boundary Events. They interrupt normal execution of the parent Activity and after their completion, the parent Activity is immediately terminated. This implies that only one such handler can be executed at a time. However, this does not restrict the modeler in specifying several interrupting handlers, if each handler refers to a different Event Declaration.

For non-interrupting Events (Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple), an unlimited number of Event Sub-Processes for the same Event Declaration can be modeled and executed in parallel. At runtime, they will be invoked in a non-deterministic order. The same restrictions apply for boundary Events. During execution of a non-interrupting Event Sub-Process, execution of the parent Activity continues as normal.

If for a given Sub-Process, both an inline Event Sub-Process and a boundary Event handler are modeled that Process the same EventDefinition, the following semantics apply:

- If the inline Event Sub-Process “rethrows” the Event after completion, the boundary Event is triggered.
- If the inline Event Sub-Process completes without “rethrowing” the Event, the Activity is considered to have
completed and normal **Sequence Flow** resumes. In other terms, the **Event Sub-Process** “absorbs” the **Event**.

**Interrupting Event Handlers (Error, Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple)**

Interrupting **Event Handlers** are those that have the `cancelActivity` attribute set to `true`. Whenever the **Event** occurs, regardless of whether the **Event** is handled inline or on the boundary, the associated **Activity** is interrupted. If an inline error handler is specified (in case of a **Sub-Process**), it is run within the context of that **Sub-Process**. If a boundary **Error Event** is present, **Sequence Flows** from that boundary **Event** are then followed. The parent **Activity** is canceled after either the error handler completes or **Sequence Flow** from the boundary **Event** is followed.

In the example above, the “Booking” **Sub-Process** has an **Error handler** that defines what should happen in case a “Booking” **Error** occurs within the **Sub-Process**, namely, the already performed bookings are canceled using **compensation**. The **Error handler** is then continued outside the **Sub-Process** through a boundary **Error Event**.

**Non-interrupting Event Handlers (Escalation, Message, Signal, Timer, Conditional, Multiple, and Parallel Multiple)**

Interrupting **Event Handlers** are those that have the `cancelActivity` attribute is set to `false`.

For **Event Sub-Processes**, whenever the **Event** occurs it is consumed and the associated **Event Sub-Process** is performed. If there are several **Events** that happen in parallel, then they are handled concurrently, i.e., several **Event Sub-Process instances** are created concurrently. The **non-interrupting Start Event** indicates that the **Event Sub-Process instance** runs concurrently to the **Sub-Process proper**.

For boundary **Events**, whenever the **Event** occurs the handler runs concurrently to the **Activity**. If an **Event Sub-Process** is also specified for that **Event** (in case of a **Sub-Process**), it is run within the context of that **Sub-Process**. Then, **Sequence Flows** from the boundary **Event** are followed. As a **token** is generated for the **Sequence Flow** from the boundary **Event** in parallel to the continuing execution of the **Activity**, care MUST be taken when this flow is merged into the main flow of the **Process** – typically it should be ended with its own **End Event**.

In the example above, an **Event Handler** allows to update the credit card information during the “Booking” **Sub-Process**. It is triggered by a credit card information **Message**: such a **Message** can be received whenever the control flow is within the main body of the **Sub-Process**. Once such a **Message** is received, the **Activities** within the corresponding **Event Handler** run concurrently with the **Activities** within the body of the **Sub-Process**.

See page 455 for the exact semantics of boundary **Intermediate Events** and page 455 for the operational semantics of non-interrupting **Event Sub-Processes**.

**Handling End Events**

For a **Terminate End Event**, all remaining active **Activities** within the **Process** are terminated.

A **Cancel End Event** is only allowed in the context of a **Transaction Sub-Process** and, as such, cancels the **Sub-Process** and aborts an associated **Transaction** of the **Sub-Process**.

For all other **End Events**, the behavior associated with the **EventDefinition** is performed. When there are no further active **Activities**, then the **Sub-Process** or **Process instance** is completed. See page 458 for exact semantics.

10.4.7 **Scopes**

A **scope** describes the context in which execution of an **Activity** happens. This consists of:
• The set of **Data Objects** available (including **DataInput** and **DataOutput**)
• The set of **Events** available for *catching* or *throwing triggers*
• The set of **Conversations** going on in that *scope*

In general, a *scope* contains exactly one main flow of **Activities** which is started, when the *scope* gets activated. Vice versa, all **Activities** are enclosed by a *scope*. **Scopes** are hierarchically nested.

**Scopes** can have several *scope instances* at runtime. They are also hierarchically nested according to their generation. In a *scope instance* several *tokens* can be active.

**Scope instances** in turn have a **lifecycle**, containing amongst others the states:

• Activated
• In execution
• Completed
• In Compensation
• Compensation
• In Error
• In Cancellation
• Cancelled

**BPMN** has the following model elements with *scope* characteristics:

• **Choreography**
• **Pool**
• **Sub-Process**
• **Task**
• **Activity**
  • *Multi-instances body*

**Scopes** are used to define the semantics of

• Visibility of **Data Objects** (including **DataInput** and **DataOutput**)
• **Event** resolution
  • Starting/stopping of *token* execution

The **Data Objects**, **Events** and **correlation keys** described by a *scope* can be explicitly modeled or implicitly defined.
### 10.4.8 Events Package XML Schemas

**Table 10.102 — BoundaryEvent XML schema**

```xml
<xsd:element name="boundaryEvent" type="tBoundaryEvent" substitutionGroup="flowElement"/>
<xsd:complexType name="tBoundaryEvent">
    <xsd:complexContent>
        <xsd:extension base="tCatchEvent">

        <xsd:element name="timeCycle" type="tExpression" minOccurs="0" maxOccurs="1"/>
      </xsd:choice>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```

## 10.5 Gateways

Gateways are used to control how Sequence Flows interact as they converge and diverge within a Process. If the flow does not need to be controlled, then a Gateway is not needed. The term “Gateway” implies that there is a gating mechanism that either allows or disallows passage through the Gateway—that is, as tokens arrive at a Gateway, they can be merged together on input and/or split apart on output as the Gateway mechanisms are invoked.

A Gateway is a diamond, which has been used in many flow chart notations for exclusive branching and is familiar to most modelers.

- A Gateway is a diamond that MUST be drawn with a single thin line (see Figure 10.102).
- The use of text, color, size, and lines for a Gateway MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41 with the exception that:

![Diamond](image)

**Figure 10.102 – A Gateway**

Gateways, like Activities, are capable of consuming or generating additional tokens, effectively controlling the execution semantics of a given Process. The main difference is that Gateways do not represent ‘work’ being done and they are considered to have zero effect on the operational measures of the Process being executed (cost, time, etc.).

Gateways can define all the types of Business Process Sequence Flow behavior: Decisions/branching (exclusive, inclusive, and complex), merging, forking, and joining. Thus, while the diamond has been used traditionally for exclusive decisions, BPMN extends the behavior of the diamonds to reflect any type of Sequence Flow control. Each type of Gateway will have an internal indicator or marker to show the type of Gateway that is being used (see Figure 10.103).
The Gateway controls the flow of both diverging and converging Sequence Flows. That is, a single Gateway could have multiple input and multiple output flows. Modelers and modeling tools might want to enforce a best practice of a Gateway only performing one of these functions. Thus, it would take two sequential Gateways to first converge and then to diverge the Sequence Flows.
Gateways are described in this section on an abstract level. The execution semantics of Gateways is detailed on page 448.

10.5.1 Sequence Flow Considerations

Note – Although the shape of a Gateway is a diamond, it is not a requirement that incoming and outgoing Sequence Flows MUST connect to the corners of the diamond. Sequence Flows can connect to any position on the boundary of the Gateway shape.

This section applies to all Gateways. Additional Sequence Flow Connection rules are specified for each type of Gateway in the sections below.

- A Gateway MAY be a target for a Sequence Flow. It can have zero (0), one (1), or more incoming Sequence Flows.
- If the Gateway does not have an incoming Sequence Flow, and there is no Start Event for the Process, then the Gateway’s divergence behavior, depending on the type of Gateway (see below), SHALL be performed when the Process is instantiated.
◆ A **Gateway** MAY be a source of a **Sequence Flow**; it can have zero (0), one (1), or more **outgoing Sequence Flows**.

◆ A **Gateway** MUST have either multiple **incoming Sequence Flows** or multiple **outgoing Sequence Flows** (i.e., it MUST merge or split the flow).
  ◆ A **Gateway** with a **gatewayDirection** of unspecified MAY have both multiple **incoming** and **outgoing Sequence Flows**.
  ◆ A **Gateway** with a **gatewayDirection** of **mixed** MUST have both multiple **incoming** and **outgoing Sequence Flows**.
  ◆ A **Gateway** with a **gatewayDirection** of **converging** MUST have multiple **incoming Sequence Flows**, but MUST NOT have multiple **outgoing Sequence Flows**.
  ◆ A **Gateway** with a **gatewayDirection** of **diverging** MUST have multiple **outgoing Sequence Flows**, but MUST NOT have multiple **incoming Sequence Flows**.

### 10.5.2 Exclusive Gateway

A diverging **Exclusive Gateway (Decision)** is used to create alternative paths within a **Process** flow. This is basically the “diversion point in the road” for a **Process**. For a given **instance** of the **Process**, only one of the paths can be taken.

A Decision can be thought of as a question that is asked at a particular point in the **Process**. The question has a defined set of alternative answers. Each answer is associated with a condition **Expression** that is associated with a **Gateway’s outgoing Sequence Flows**.

◆ The **Exclusive Gateway** MAY use a marker that is shaped like an “X” and is placed within the **Gateway** diamond (see Figure 10.106) to distinguish it from other **Gateways**. This marker is NOT REQUIRED (see Figure 10.105).

◆ A diagram SHOULD be consistent in the use of the “X” internal indicator. That is, a diagram SHOULD NOT have some **Gateways** with an indicator and other **Gateways** without an indicator.

![Figure 10.105 - An Exclusive Data-Based Decision (Gateway) Example without the Internal Indicator](image)
Figure 10.106 - A Data-Based Exclusive Decision (Gateway) Example with the Internal Indicator

**Note** – as a modeling preference, the **Exclusive Gateways** shown in examples within this specification will be shown without the internal indicator.

A default path can optionally be identified, to be taken in the event that none of the conditional **Expressions** evaluate to **true**. If a default path is not specified and the **Process** is executed such that none of the conditional **Expressions** evaluates to **true**, a runtime exception occurs.

A converging **Exclusive Gateway** is used to merge alternative paths. Each **incoming Sequence Flow token** is routed to the **outgoing Sequence Flow** without synchronization.

Figure 10.107 - Exclusive Gateway class diagram
The **Exclusive Gateway** element inherits the attributes and model associations of **Gateway** (see Table 8.46). Table 10.123 presents the additional attributes and model associations of the **Exclusive Gateway** element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>default: SequenceFlow [0..1]</td>
<td>The Sequence Flow that will receive a token when none of the conditionExpressions on other outgoing Sequence Flows evaluate to true. The default Sequence Flow should not have a conditionExpression. Any such Expression SHALL be ignored.</td>
</tr>
</tbody>
</table>

### 10.5.3 Inclusive Gateway

A diverging **Inclusive Gateway** (Inclusive Decision) can be used to create alternative but also parallel paths within a **Process** flow. Unlike the **Exclusive Gateway**, all condition Expressions are evaluated. The true evaluation of one condition Expression does not exclude the evaluation of other condition Expressions. All **Sequence Flows** with a true evaluation will be traversed by a token. Since each path is considered to be independent, all combinations of the paths MAY be taken, from zero to all. However, it should be designed so that at least one path is taken.

- The **Inclusive Gateway** MUST use a marker that is in the shape of a circle or an “O” and is placed within the **Gateway** diamond (see Figure 10.108) to distinguish it from other **Gateways**.

![Figure 10.108 - An example using an Inclusive Gateway](image)

A default path can optionally be identified, to be taken in the event that none of the conditional Expressions evaluate to true. If a default path is not specified and the **Process** is executed such that none of the conditional Expressions evaluates to true, a runtime exception occurs.

A converging **Inclusive Gateway** is used to merge a combination of alternative and parallel paths. A control flow token arriving at an **Inclusive Gateway** MAY be synchronized with some other tokens that arrive later at this **Gateway**. The precise synchronization behavior of the **Inclusive Gateway** can be found on page 300.
The **Inclusive Gateway** element inherits the attributes and model associations of **Gateway** (see Table 8.46). Table 10.124 presents the additional attributes and model associations of the **Inclusive Gateway** element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>default: SequenceFlow [0..1]</td>
<td>The <strong>Sequence Flow</strong> that will receive a <strong>token</strong> when none of the conditionExpressions on other <strong>Sequence Flows</strong> evaluate to <strong>true</strong>. The <strong>default</strong> <strong>Sequence Flow</strong> should not have a <strong>conditionExpression</strong>. Any such <strong>Expression</strong> SHALL be ignored.</td>
</tr>
</tbody>
</table>

### 10.5.4 Parallel Gateway

A **Parallel Gateway** is used to synchronize (combine) parallel flows and to create parallel flows.

- The **Parallel Gateway** MUST use a marker that is in the shape of a plus sign and is placed within the **Gateway** diamond (see Figure 10.110) to distinguish it from other **Gateways**.
**Parallel Gateways** are used for synchronizing parallel flow (see Figure 10.111).

A **Parallel Gateway** creates parallel paths without checking any conditions; each *outgoing Sequence Flow* receives a *token* upon execution of this **Gateway**. For *incoming* flows, the **Parallel Gateway** will wait for all *incoming* flows before triggering the flow through its *outgoing Sequence Flows*.
Figure 10.112 - Parallel Gateway class diagram

The Parallel Gateway element inherits the attributes and model associations of Gateway (see Table 8.46), but adds no additional attributes or model associations.

10.5.5 Complex Gateway

The Complex Gateway can be used to model complex synchronization behavior. An Expression activationCondition is used to describe the precise behavior. For example, this Expression could specify that tokens on three out of five incoming Sequence Flows are needed to activate the Gateway. What tokens are produced by the Gateway is determined by conditions on the outgoing Sequence Flows as in the split behavior of the Inclusive Gateway. If tokens arrive later on the two remaining Sequence Flows, those tokens cause a reset of the Gateway and new token can be produced on the outgoing Sequence Flows. To determine whether it needs to wait for additional tokens before it can reset, the Gateway uses the synchronization semantics of the Inclusive Gateway.

◆ The Complex Gateway MUST use a marker that is in the shape of an asterisk and is placed within the Gateway diamond (see Figure 10.113) to distinguish it from other Gateways.

Figure 10.113 - An example using a Complex Gateway
The **Complex Gateway** has, in contrast to other **Gateways**, an internal state, which is represented by the boolean instance attribute `waitingForStart`, which is initially `true` and becomes `false` after activation. This attribute can be used in the conditions of the *outgoing Sequence Flows* to specify where tokens are produced upon activation and where tokens are produced upon reset. It is RECOMMENDED that each *outgoing Sequence Flow* either get a `token` upon activation or upon reset but not both. At least one *outgoing Sequence Flow* should receive a `token` upon activation but a `token` MUST NOT be produced upon reset.

Figure 10.114 shows the class diagram for the **Complex Gateway**.

![Complex Gateway class diagram](image)

Figure 10.114 - Complex Gateway class diagram

The **Complex Gateway** element inherits the attributes and model associations of **Gateway** (see Table 8.46). Table 10.125 presents the additional model associations of the **Complex Gateway** element:

**Table 10.125 – Complex Gateway model associations**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>activationCondition: Expression [0..1]</td>
<td>Determines which combination of <em>incoming tokens</em> will be synchronized for activation of the <strong>Gateway</strong>.</td>
</tr>
<tr>
<td>default: SequenceFlow [0..1]</td>
<td>The <strong>Sequence Flow</strong> that will receive a <code>token</code> when none of the conditionExpressions on other <strong>Sequence Flows</strong> evaluate to <code>true</code>. The <code>default</code> <strong>Sequence Flow</strong> should not have a conditionExpression. Any such Expression SHALL be ignored.</td>
</tr>
</tbody>
</table>
10.5.6 Event-Based Gateway

The **Event-Based Gateway** represents a branching point in the **Process** where the alternative paths that follow the **Gateway** are based on **Events** that occur, rather than the evaluation of **Expressions** using **Process** data (as with an **Exclusive** or **Inclusive Gateway**). A specific **Event**, usually the receipt of a **Message**, determines the path that will be taken. Basically, the **decision** is made by another **Participant**, based on data that is not visible to **Process**, thus, requiring the use of the **Event-Based Gateway**.

For example, if a company is waiting for a response from a customer they will perform one set of **Activities** if the customer responds “Yes” and another set of **Activities** if the customer responds “No.” The customer’s response determines which path is taken. The identity of the **Message** determines which path is taken. That is, the “Yes” **Message** and the “No” **Message** are different **Messages**—i.e., they are not the same **Message** with different values within a property of the **Message**. The receipt of the **Message** can be modeled with an **Intermediate Event** with a **Message trigger** or a **Receive Task**. In addition to **Messages**, other **triggers** for **Intermediate Events** can be used, such as **Timers**.

The **Event Gateway** shares the same basic shape of the **Gateways**, a diamond, with a marker placed within the diamond to indicate variations of the **Gateway**.

- An **Event Gateway** is a diamond that MUST be drawn with a single thin line.
- The use of text, color, size, and lines for an **Event Gateway** MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.
- The marker for the **Event Gateway** MUST look like a catch **Multiple Intermediate Event** (see Figure 10.115).

**Table 10.126 – Instance attributes related to the Complex Gateway**

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>activationCount: integer</td>
<td>Refers at runtime to the number of tokens that are present on an incoming Sequence Flow of the Complex Gateway.</td>
</tr>
<tr>
<td>waitingForStart: boolean = true</td>
<td>Represents the internal state of the Complex Gateway. It is either waiting for start (=true) or waiting for reset (=false).</td>
</tr>
</tbody>
</table>

**Figure 10.115 – Event-Based Gateway**

Unlike other **Gateways**, the behavior of the **Event Gateway** is determined by a configuration of elements, rather than the single **Gateway**.

- An **Event Gateway** MUST have two (2) or more outgoing **Sequence Flows**.
- The outgoing **Sequence Flows** of the **Event Gateway** MUST NOT have a conditionExpression.
The objects that are on the target end of the **Gateway’s outgoing Sequence Flows** are part of the configuration of the Gateway.

- **Event-Based Gateways** are configured by having **outgoing Sequence Flows** target an **Intermediate Event** or a **Receive Task** in any combination (see Figure 10.116 and Figure 10.117) except that:
  - If **Message Intermediate Events** are used in the configuration, then **Receive Tasks** MUST NOT be used in that configuration and vice versa.
  - **Receive Tasks** used in an **Event Gateway** configuration MUST NOT have any attached **Intermediate Events**.
  - Only the following **Intermediate Event triggers** are valid: Message, Signal, Timer, Conditional, and Multiple (which can only include the previous triggers). Thus, the following **Intermediate Event triggers** are not valid: Error, Cancel, Compensation, and Link.
  - Target elements in an **Event Gateway** configuration MUST NOT have any additional **incoming Sequence Flows** (other than that from the **Event Gateway**).

![An Event-Based Gateway example using Message Intermediate Events](image)

**Figure 10.116 - An Event-Based Gateway example using Message Intermediate Events**
When the first Event in the Event Gateway configuration is triggered, then the path that follows that Event will used (a token will be sent down the Event’s outgoing Sequence Flows). All the remaining paths of the Event Gateway configuration will no longer be valid. Basically, the Event Gateway configuration is a race condition where the first Event that is triggered wins.

There are variations of the Event Gateway that can be used at the start of the Process. The behavior and marker of the Gateway will change.

Event Gateways can be used to instantiate a Process. By default the Gateway’s instantiate attribute is false, but if set to true, then the Process is instantiated when the first Event of the Gateway’s configuration is triggered.

- If the Event Gateway’s instantiate attribute is set to true, then the marker for the Event Gateway looks like a Multiple Start Event (see Figure 10.118).

In order for an Event Gateway to instantiate a Process, it MUST not have any incoming Sequence Flows:

In some situations a modeler might want the Process to be instantiated by one of a set of Messages while still requiring all of the Messages for the working of the same Process instance. To handle this, there is another variation of the Event Gateway.

- If the Event Gateway’s instantiate attribute is set to true and the eventGatewayType attribute is set to Parallel, then the marker for the Event Gateway looks like a Parallel Multiple Start Event (see Figure 10.119).

- The Event Gateway’s instantiate attribute MUST be set to true in order for the eventGatewayType
attribute to be set to Parallel (i.e., for Event Gateway’s that do not instantiate the Process MUST be Exclusive—a standard Parallel Gateway can be used to include parallel Events in the middle of a Process).

Figure 10.119 – Parallel Event-Based Gateway to start a Process

The Parallel Event Gateway is also a type of race condition. In this case, however, when the first Event is triggered and the Process is instantiated, the other Events of the Gateway configuration are not disabled. The other Events are still waiting and are expected to be triggered before the Process can (normally) complete. In this case, The Messages that trigger the Events of the Gateway configuration MUST share the same correlation information.

Figure 10.120 - Event-Based Gateway class diagram

The Event-Based Gateway element inherits the attributes and model associations of Gateway (see Table 8.46). Table 10.127 presents the additional attributes and model associations of the Event-Based Gateway element:
Event-Based Gateways can be used at the start of a Process, without having to be a target of a Sequence Flows. There can be multiple such Event-Based Gateways at the start of a Process. Ordinary Start Events and Event-Based Gateways can be used together.

10.6 Compensation

Compensation is concerned with undoing steps that were already successfully completed, because their results and possibly side effects are no longer desired and need to be reversed. If an Activity is still active, it cannot be compensated, but rather needs to be canceled. Cancellation in turn can result in compensation of already successfully completed portions of an active Activity, in case of a Sub-Process.

Compensation is performed by a compensation handler. A compensation handler performs the steps necessary to reverse the effects of an Activity. In case of a Sub-Process, the compensation handler has access to Sub-Process data at the time of its completion (“snapshot data”).

Compensation is triggered by a throw Compensation Event, which typically will be raised by an error handler, as part of cancellation, or recursively by another compensation handler. That Event specifies the Activity for which compensation is to be performed, either explicitly or implicitly.

10.6.1 Compensation Handler

A compensation handler is a set of Activities that are not connected to other portions of the BPMN model. The compensation handler starts with a catch Compensation Event. That catch Compensation Event either is a boundary Event, or, in case of a Compensation Event Sub-Process, the handler’s Start Event.

A compensation handler connected via a boundary Event can only perform “black-box” compensation of the original Activity. This compensation is modeled with a specialized Compensation Activity, which is connected to the boundary Event through an Association (see Figure 10.121). The Compensation Activity, which can be either a Task or a Sub-Process, has a marker to show that it is used for compensation only and is outside the normal flow of the Process.

Figure 10.121 - Compensation through a boundary Event

A Compensation Event Sub-Process is contained within a Process or a Sub-Process (see Figure 10.122). Like the Compensation Activity, the Compensation Event Sub-Process is outside the normal flow of the Process. The Event Sub-Process, which is marked with a dotted line boundary, can access data that is part of its parent, a snapshot at the point in time when its parent completed. A Compensation Event Sub-Process can recursively trigger compensation for Activities contained in its parent.
It is possible to specify that a **Sub-Process** can be compensated without having to define the *compensation handler*. The **Sub-Process** attribute `compensable`, when set, specifies that default *compensation* is implicitly defined, which recursively compensates all successfully completed **Activities** within that **Sub-Process**.

The example in Figure 10.122, above contains a custom **Compensation Event Sub-Process**, triggered by a **Compensation Start Event**. Note that this *compensation handler* deviates from default *compensation* in that it runs **Compensation Activities** in an order different from the order in the forward case; it also contains an additional **Activity** adding **Process** logic that cannot be derived from the body of the **Sub-Process** itself.

### 10.6.2 Compensation Triggering

**Compensation** is triggered using a *compensation throw Event*, which can either be an **Intermediate** or an **End Event**. The **Activity** which needs to be compensated is referenced. If the **Activity** is clear from the context, it doesn’t have to be specified and defaults to the current **Activity**. A typical scenario for that is an inline *error handler* of a **Sub-Process** that cannot recover the *error*, and as a result would trigger *compensation* for that **Sub-Process**. If no **Activity** is specified in a “global” context, all completed **Activities** in the **Process** are compensated.

By default, *compensation* is triggered synchronously, that is, the *compensation throw Event* waits for the completion of the triggered *compensation handler*. Alternatively, *compensation* can just be triggered without waiting for its completion, by setting the **throw Compensation Event**’s `waitForCompletion` attribute to `false`.

Multiple instances typically exist for **Loop** or **Multi-Instance Sub-Processes**. Each of these has its own instance of its **Compensation Event Sub-Process**, which has access to the specific snapshot data that was current at the time of completion of that particular instance. Triggering *compensation* for the **Multi-Instance Sub-Process** individually
triggers \textit{compensation} for all \textit{instances} within the current \textit{scope}. If \textit{compensation} is specified via a boundary \textit{compensation handler}, this boundary \textit{compensation handler} also is invoked once for each \textit{instance} of the \textbf{Multi-Instance Sub-Process} in the current \textit{scope}.

\section*{10.6.3 Relationship between Error Handling and Compensation}

The following items define the relationship between \textit{error handling} and \textit{compensation}:

- \textit{Compensation} employs a “presumed abort principle”, with the following consequences: \textit{Compensation} of a failed \textbf{Activity} results in a null operation.

- When an \textbf{Activity} fails, i.e., is left because an \textit{error} has been thrown, it’s the \textit{error handlers} responsibility to ensure that no further \textit{compensation} will be necessary once the \textit{error handler} has completed.

- If no \textit{error Event Sub-Process} is specified for a particular \textbf{Sub-Process} and a particular \textit{error}, the default behavior is to automatically call \textit{compensation} for all contained \textbf{Activities} of that \textbf{Sub-Process} if that \textit{error} is thrown, ensuring the behavior in for \textit{auditing} and \textit{monitoring}.

\section*{10.7 Lanes}

A \textbf{Lane} is a sub-partition within a \textbf{Process} (often within a \textbf{Pool}) and will extend the entire length of the \textbf{Process} level., either vertically (see Figure 10.122) or horizontally (see Figure 10.123). Text associated with the \textbf{Lane} (e.g., its name and/or that of any \textbf{Process} element attribute) can be placed inside the shape, in any direction or location, depending on the preference of the modeler or modeling tool vendor. Our examples place the name as a banner on the left side (for horizontal \textbf{Pools}) or at the top (for vertical \textbf{Pools}) on the other side of the line that separates the \textbf{Pool} name, however, this is not a requirement.

- A \textbf{Lane} is a square-cornered rectangle that MUST be drawn with a solid single line (see Figure 10.123 and Figure 10.124).

- The label for the \textbf{Lane} MAY be placed in any location and direction within the \textbf{Lane}, but MUST NOT be separated from the contents of the \textbf{Lane} by a single line (except in the case that there are sub-\textbf{Lanes} within the \textbf{Lane}).
Lanes are used to organize and categorize Activities within a Pool. The meaning of the Lanes is up to the modeler. BPMN does not specify the usage of Lanes. Lanes are often used for such things as internal roles (e.g., Manager, Associate), systems (e.g., an enterprise application), an internal department (e.g., shipping, finance), etc. In addition, Lanes can be nested (see Figure 10.125) or defined in a matrix. For example, there could be an outer set of Lanes for company departments and then an inner set of Lanes for roles within each department.
Figure 10.126 shows the **Lane** class diagram. When a **Lane** is defined it is contained within a **LaneSet**, which is contained within a **Process**.
The LaneSet element defines the container for one or more Lanes. A Process can contain one or more LaneSets. Each LaneSet and its Lanes can partition the Flow Nodes in a different way.

The LaneSet element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.134 presents the additional attributes and model associations of the LaneSet element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>name: string [0..1]</td>
<td>The name of the LaneSet. A LaneSet is not visually displayed on a BPMN diagram. Consequently, the name of the LaneSet is not displayed as well.</td>
</tr>
<tr>
<td>process: Process</td>
<td>The Process owning the LaneSet</td>
</tr>
<tr>
<td>lanes: Lane [0..*]</td>
<td>One or more Lane elements, which define a specific partition in the LaneSet</td>
</tr>
<tr>
<td>parentLane: Lane [0..1]</td>
<td>The reference to a Lane element which is the parent of this LaneSet.</td>
</tr>
</tbody>
</table>

A Lane element defines one specific partition in a LaneSet. The Lane can define a partition element which specifies the value and element type, a tool can use to determine the list of Flow Nodes to be partitioned into this Lane. All Lanes in a single LaneSet MUST define partition element of the same type, e.g., all Lanes in a LaneSet reference a Resource as the partition element, but each Lane references a different Resource instance.

The Lane element inherits the attributes and model associations of BaseElement (see Table 8.5). Table 10.135 presents the additional attributes and model associations of the Lane element:
10.8 Process Instances, Unmodeled Activities, and Public Processes

A Process can be executed or performed many times, but each time is expected to follow the steps laid out in the Process model. For example, the Process in Figure 10.1 will occur every Friday, but each instance is expected to perform Task “Receive Issue List,” then Task “Review Issue List,” and so on, as specified in the model. Each instance of a Process is expected to be valid for the model, but some instances might not, for example if the Process has manual Activities, and the performers have not had proper instruction on how to carry out the Process.

In some applications it is useful to allow more Activities and Events to occur when a Process is executed or performed than are contained in the Process model. This enables other steps to be taken as needed without changing the Process. For example, instances of the Process in Figure 10.1 might execute or perform an extra Activity between Task “Receive Issue List” and Task “Review Issue List.” These instances are still valid for the Process model in Figure 10.1, because the instances still execute or perform the Activities in the Process, in the order they are modeled and under conditions specified for them.

There are two ways to specify whether unmodeled Activities are allowed to occur in Process instances:

- If the isClosed attribute of a Process has a value of false or no value, then interactions, such as sending and receiving Messages and Events, MAY occur in an instance without additional flow elements in the Process. Unmodeled interactions can still be restricted on particular Sequence Flow in the Process (see next bullet). If the isClosed attribute of a Process has a value of true, then interactions, such as sending and receiving Messages and Events, MAY NOT occur without additional flow elements in the Process. This restriction overrides any unmodeled interactions allowed by Sequence Flows in the next bullet.

- If the isImmediate attribute of a Sequence Flow in a Process has a value of false, then other Activities and interactions not modeled in the Process MAY be executed or performed during the Sequence Flow. If the isImmediate attribute has a value of true, then Activities and interactions not modeled in the Process MAY NOT be executed or performed during Sequence Flow. In non-executable Processes (isExecutable attribute has value false, or defaults to false), Sequence Flows with no value for isImmediate are treated as if the

</tr>
</tbody>
</table>
value were false. In executable Processes (isExecutable attribute has value true, or defaults to true), Sequence Flows with no value for isImmediate are treated as if the value were true. Executable Processes cannot have a false value for the isImmediate attribute.

Restrictions on unmodeled Activities specified with isClosed and isImmediate apply only under executions or performances (instances) of the Process containing the restriction. These Activities MAY occur in instances of other Processes.

When a Process allows Activities to occur that the Process does not model, those Activities might appear in other Process models. The executions or performances (instances) of these other Processes might be valid for the original Process. For example, a Process might be defined similar to the one in Figure 10.1 that adds an extra Activity between Task “Receive Issue List” and Task “Review Issue List.” The Process in Figure 10.1 might use isClosed or isImmediate to allow other Activities to occur in between Task “Receive Issue List” and Task “Review Issue List.” When the Process is executed or performed, then instances of the other Process (the one with the extra step in between Task “Receive Issue List” and Task “Review Issue List”) will be valid for the Process in Figure 10.1. Modelers can declare that they intend all instances of one Process will be valid for another Process using the supports association between the Processes. During development of these Processes, support might not actually hold, because the association just expresses modeler intent.

A common use for model support is between private and public Processes, see Section “Overview” (page 23). A public Process contain Activities visible to external parties, such as Participants in a Collaboration, while a private Process includes other Activities that are not visible to external parties. The hidden Activities in a private Process are not modeled in the public Process. However, it is expected that instances of the private Process will appear to external parties as if they could be instances of the public Process. This means the private Process supports the public Process (it is expected that all instances of the private Process will be valid for the public one).

A Process that supports another, as a private Process can to a public Process, does not need to be entirely similar to the other Process. It is only REQUIRED that instances of the Process appear as if they could be instance of the other Process. For example Figure 10.127 shows a public Process at the top with a Send Task and Receive Task. A supporting private Process is shown at the bottom. The private Process sends and receives the same Messages, but using Events instead of Tasks. It also introduces Activities not modeled in the public Process. However all instances of the private Process will appear as if they could be instances of the public one, because the Messages are sent and received in the order REQUIRED by the public Process, and the public Process allows unmodeled Activities to occur.
In practice, a public Process looks like an underspecified private Process. Anything not specified in the public Process is determined by the private one. For example, if none of the outgoing Sequence Flows for an Exclusive Gateway have conditionExpressions, the private Process will determine which one of the Activities targeted by the Sequence Flows will occur. Another example is a Timer Event with no EventDefinition. The private Process will determine when the timer goes off.

10.9 Auditing

The Auditing element and its model associations allow defining attributes related to auditing. It leverages the BPMN extensibility mechanism. This element is used by FlowElements and Process. The actual definition of auditing attributes is out of scope of this specification. BPMN 2.0 implementations can define their own set of attributes and their intended semantics.
10.10 Monitoring

The Monitoring and its model associations allow defining attributes related to monitoring. It leverages the BPMN extensibility mechanism. This element is used by FlowElements and Process. The actual definition of monitoring attributes is out of scope of this specification. BPMN 2.0 implementations can define their own set of attributes and their intended semantics.

11 Choreography

Note – The content of this chapter is REQUIRED for BPMN Choreography Modeling Conformance or for BPMN Complete Conformance. However, this chapter is NOT REQUIRED for BPMN Process Modeling Conformance, BPMN Process Execution Conformance, or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 2.

A Choreography is a type of process, but differs in purpose and behavior from a standard BPMN Process. A standard Process, or an Orchestration Process (see page 149), is more familiar to most process modelers and defines the flow of Activities of a specific PartnerEntity or organization. In contrast, Choreography formalizes the way business Participants coordinate their interactions. The focus is not on orchestrations of the work performed within these Participants, but rather on the exchange of information (Messages) between these Participants.

Another way to look at Choreography is to view it as a type of business contract between two (2) or more organizations. This entails Message (document) exchanges in an orderly fashion: e.g., first a retailer sends a purchase order request to a supplier; next the supplier either confirms or rejects intention to investigate the order; then supplier proceeds to investigate stock for line-items and seeks outside suppliers if necessary; accordingly the supplier sends a confirmation or rejection back; during this period the retailer can send requests to vary the order, etc.

Message exchanges between partners go beyond simple request-response interactions into multi-cast, contingent requests, competing receives, streaming and other service interaction patterns (REF for SIP). Moreover, they cluster around distinct scenarios such as: creation of sales orders; assignment of carriers of shipments involving different sales orders; managing the “red tape” of crossing customs and quarantine; processing payment and investigating exceptions. A Choreography is a definition of expected behavior, basically a procedural business contract, between interacting Participants (see page 112 for more information on Participants). It brings Message exchanges and their logical relation as Conversations into view. This allows partners to plan their Business Processes for inter-operation without introducing conflicts. An example of a conflict could arise if a retailer was allowed to send a variation on a purchase order immediately after sending the initial request. The Message exchange sequences in Choreography models need to be reflected in the orchestration Processes of participants. A Choreography model makes it possible to derive the Process interfaces of each partner’s Process (REF: Decker & Weske, 2007).

To leverage the familiarity of flow charting types of Process models, BPMN Choreographies also have “activities” that are ordered by Sequence Flows. These “activities” consist of one (1) or more interactions between Participants. These interactions are often described as being message exchange patterns (MEPs). A MEP is the atomic unit (“Activity”) of a Choreography.

Some MEPs involve a single Message (e.g., a “Customer” requests an “Order” from a “Supplier”). Other MEPs will involve two (2) Messages in a request and response format (e.g., a “Supplier” request a “Credit Rating” from a “Financial Institution,” who then returns the “Credit Rating” to the “Supplier”). There can be even more complex MEPs that involve error Messages, for example.

A single MEP can be defined as a BPMN Choreography Task (see page 333). Thus, a Choreography defines the order in which Choreography Tasks occur. Sub-Choreographies allow the composition/decomposition of Choreographies.

Choreographies are designed in BPMN to allow stand-alone, scalable models of these Participant interactions. However, since BPMN provides other Business Process modeling views, Choreographies are designed to fit within BPMN Collaboration diagrams to display of the relationship between the Choreography and Orchestration Processes (thus, expanding BPMN 1.2 capabilities—see page 109, above, for more information on Collaborations, and page 372 for Choreographies within Collaborations).
Figure 11.1 displays the metamodel of the key BPMN elements that contribute to Choreography modeling. The sections of this chapter will describe the characteristics of these elements and how they are used in a Choreography.

![Figure 11.1 - The Choreography metamodel](image)

**Note** – The Choreography element inherits the attributes and model associations of Collaboration (see Table 9.1) and of FlowElementContainer (see Table 8.45), but does not have any additional attributes or model associations. The Collaboration attribute choreographyRef is not applicable to Choreography.

### 11.1 Basic Choreography Concepts

A key to understanding Choreographies and how they are used in BPMN is their relationship to Pools (see page 112 for more information on Pools). Choreographies exist outside of or in between Pools. A Process, within a Pool, represents the work of a specific PartnerEntity (e.g., “FedEx”), often substituted by a PartnerRole (e.g., “Shipper”) when a PartnerEntity is not identified and can be decided later. The PartnerEntity/PartnerRole is called a Participant in BPMN. Pools are the graphical representation of Participants. A Choreography, on the other hand, is a different kind of process. A Choreography defines the sequence of interactions between Participants. Thus,
a **Choreography** does not exist in a single **Pool**—it is not the purview of a single **Participant**. Each step in the **Choreography** involves two (2) or more **Participants** (these steps are called **Choreography Activities**—see below). This means that the **Choreography**, in **BPMN** terms, is defined outside of any particular **Pool**.

The key question that needs to be continually asked during the development of a **Choreography** is “what information do the **Participants** in the **Choreography** have?” Basically, each **Participant** can only understand the status of the **Choreography** through observable behavior of the other **Participants**—which are the **Messages** that have been sent and received. If there are only two (2) **Participants** in the **Choreography**, then it is very simple—both **Participants** will be aware of who is responsible for sending the next **Message**. However, if there are more than two (2) **Participants**, then the modeler needs to be careful to sequence the **Choreography Activities** in such a way that the **Participants** know when they are responsible for initiating the **interactions**.

Figure 11.2 presents a sample **Choreography**. The details of **Choreography** behavior and elements will be described in the sections below.

---

**Figure 11.2 - An example of a Choreography**

To illustrate the correspondence between **Collaboration** and **Choreography**, consider an example from logistics. Figure 11.3 shows a **Collaboration** where the **Pools** are expanded to reveal orchestration details per participant (for **Shipper**; **Retailer** etc). **Message Flows** connect the elements in the different **Pools** related to different participants, indicating **Message exchanges**. For example, a **Planned Order Variations Message** is sent by the **Supplier** to the **Retailer**; the corresponding send and receive have been modeled using regular **BPMN** messaging **Activities**. Also, a number of **Messages** of the same type being sent, for example a number of **Retailer Order and Delivery Variations Messages** can be sent from the **Retailer** to the **Supplier**, indicated by respective **multi-instances** constructs (for brevity, the actual elements for sending/receiving inside the **multi-instances** construct have been omitted).
The scenario modeled in Figure 11.3 entails shipment planning for the next supply replenishment variations: the Supplier confirms all previously accepted variations for delivery with the Retailer; the Retailer sends back a number of further possible variations; the Supplier requests to the Shipper and Consignee possible changes in delivery; accordingly, the Retailer interacts with the Consignee and Supplier for final confirmations.

A problem with model interconnections for complex Choreographies is that they are vulnerable to errors – interconnections might not be sequenced correctly, since the logic of Message exchanges is considered from each partner at a time. This in turn leads to deadlocks. For example, consider the PartnerRole of Retailer in Figure 11.3 and assume that, by error, the order of Confirmation Delivery Schedule and Retailer Confirmation received (far right) were swapped. This would result in a deadlock since both, Retailer and Consignee would wait for the other to send a Message. Deadlocks in general, however, are not that obvious and might be difficult to recognize in a Collaboration.

Figure 11.4 shows the Choreography corresponding to the Collaboration of Figure 11.3 above.
11.2 Data

A Choreography does not have a central control mechanism and, thus, there is no mechanism for maintaining any central Process (Choreography) data. Thus, any element in a Process that would normally depend on conditional or assignment expressions, would not have any central source for this data to be maintained and understood by all the Participants involved in the Choreography.

As mentioned above, neither Data Objects nor Repositories are used in Choreographies. Both of these elements are used exclusively in Processes and require the concept of a central locus of control. Data Objects are basically variables and there would be no central system to manage them. Data can be used in expressions that are used in Exclusive Gateways, but only that data which has been sent through a Message in the Choreography.

11.3 Use of BPMN Common Elements

Some BPMN elements are common to both Process and Choreography diagrams, as well as Collaboration; they are used in these diagrams. The next few sections will describe the use of Messages, Message Flows, Participants, Sequence Flows, Artifacts, Correlations, Expressions, and Services in Choreography.

The key graphical elements of Gateways and Events are also common to both Choreography and Process. Since their usage has a large impact, they are described in major sections of this chapter (see page 350 for Events and page 355 for Gateways).
11.3.1 Sequence Flow

Sequence Flows are used within Choreographies to show the sequence of the Choreography Activities, which can have intervening Gateways. They are used in the same way as they are in Processes. They are only allowed to connect with other Flow Objects. For Processes, they can only connect Events, Gateways, and Activities. For Choreographies, they can only connect Events, Gateways, and Choreography Activities (see Figure 11.5).

Figure 11.5 - The use of Sequence Flows in a Choreography

There are two additional variations of Sequence Flows:

- **Conditional Sequence Flows**: Conditions can be added to Sequence Flows in two situations:
  - From Gateways: Outgoing Sequence Flows have conditions for Exclusive and Inclusive Gateways. The data referenced in the conditions need to be visible to two (2) or more Participants in the Choreography. The data becomes visible if it is part of a Message that had been sent (previously) within the Choreography. See page 355 and page 362 for more information about how Exclusive and Inclusive Gateways are used in Choreography.
  - From Choreography Activities: Outgoing Sequence Flows MAY have conditions for Choreography Activities. Since these act similar to Inclusive Gateways, the Conditional Sequence Flows can be used in Choreographies. The conditions have the same restrictions that apply to the visibility of the data for Gateways.

- **Default Sequence Flows**: For Exclusive Gateways, Inclusive Gateways, and Choreography Activities that have Conditional Sequence Flows, one of the outgoing Sequence Flows MAY be a Default Sequence Flow. Because the other outgoing Sequence Flows will have appropriately visible of data as described above, the Participants would know if all the other conditions would be false, thus the Default Sequence Flow would be selected and the Choreography would move down that Sequence Flow.

In some applications it is useful to allow additional Messages that are not part of the defined Choreography model to be sent between Participants when the Choreography is carried out. This enables Participants to exchange other Messages as needed without changing the Choreography. There are two ways to specify this:

- If the isClosed attribute (from Collaboration) of a Choreography has a value of false or no value, then Participants MAY send Messages to each other without additional Choreography Activities in the Choreography. Unmodeled messaging can be restricted on particular Sequence Flows in the Choreography.
see next bullet. If the isClosed attribute of a Choreography has a value of true, then Participants MAY NOT send Messages to each other without additional Choreography Activities in the Choreography. This restriction overrides any unmodeled messaging allowed by Sequence Flows in the next bullet.

- If the isImmediate attribute of a Sequence Flow has a value of false or no value, then Participants MAY send Messages to each other between the elements connected by the Sequence Flow without additional Choreography Activities in the Choreography. If the isImmediate attribute of a Sequence Flow has a value of true, then Participants MAY NOT send Messages to each other between the elements connected by the Sequence Flow without additional Choreography Activities in the Choreography. The value of isImmediate attribute of a Sequence Flow has no effect if the isClosed attribute of the containing Choreography has a value of true.

Restrictions on unmodeled messaging specified with isClosed and isImmediate applies only under the Choreography containing the restriction. PartnerEntities and PartnerRoles of the Participants MAY send Messages to each other under other Choreographies, Collaborations, and Conversations.

11.3.2 Artifacts

Both Text Annotations and Groups can be used within Choreographies and all BPMN diagrams. There are no restrictions on their use.

11.4 Choreography Activities

A Choreography Activity represents a point in a Choreography flow where an interaction occurs between two (2) or more Participants.

The Choreography Activity class is an abstract element, sub-classing from FlowElement (as shown in Figure 11.6). When Choreography Activities are defined they are contained within a Choreography or a Sub-Choreography, which are FlowElementContainers (other FlowElementContainers are not allowed to contain Choreography Activities).
The **Choreography Activity** element inherits the attributes and model associations of **FlowElement** (see Table 8.44) through its relationship to **FlowNode**. Table 11.1 presents the additional model associations of the **Choreography Activity** element.

**Table 11.1 – Choreography Activity Model Associations**

</tr>
</tbody>
</table>
11.4.1 Choreography Task

A Choreography Task is an atomic Activity in a Choreography Process. It represents an Interaction, which is one (1) or two (2) Message exchanges between two (2) Participants. Using a Collaboration diagram to view these elements (see page 109 for more information on Collaboration), we would see the two (2) Pools representing the two (2) Participants of the Interaction (see Figure 11.7). The communication between the Participants is shown as a Message Flow.

![Collaboration view of Choreography Task elements](image)

Figure 11.7 - A Collaboration view of Choreography Task elements

In a Choreography diagram, this Interaction is collapsed into a single object, a Choreography Task. The name of the Choreography Task and each of the Participants are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) or more Participant Bands and one Task Name Band (see Figure 11.8).

◆ The Participant Band of the Participant that does not initiate the interaction MUST be shaded with a light fill.

![Choreography Task](image)

Figure 11.8 - A Choreography Task
Figure 11.9 - A Collaboration view of a Choreography Task

The interaction defined by a **Choreography Task** can be shown in an expanded format through a **Collaboration** diagram (see Figure 11.9, above—see page 109 for more information on **Collaborations**). In the **Collaboration** view, the **Participants** of the **Choreography Task Participant Band's** will be represented by **Pools**. The interaction between them will be a **Message Flow**.

Figure 11.10 - A two-way Choreography Task
Figure 11.11 - A Collaboration view of a two-way Choreography Task

In a Choreography Diagram, the Choreography Task object shares the same shape as a Task or any other BPMN Activity, which is a rectangle that has rounded corners.

- A Choreography Task is a rounded corner rectangle that MUST be drawn with a single line.
- The use of text, color, size, and lines for a Choreography Task MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

The three (3) bands in the Choreography Task shape provide the distinction between this type of Task and an Orchestration Task (in a traditional BPMN diagram).

The Message sent by either one or both of the Participants of the Choreography Task can be displayed (see Figure 11.10, above). The Message icon is shown tethered to the Participant that is the sender of the Message.

- If the Message is the initiating Message of the Choreography Task, then the Message icon MUST be unfilled.
- If the Message is a return Message for the Choreography Task, then the Message icon MUST have a light fill.

Note that Messages can be tethered to a Call Choreography that references a GlobalChoreographyTask, but cannot be used for Sub-Choreographies or Call Choreography that references another Choreography.

As with a standard Orchestration Task, the Choreography Task MAY have internal markers to show how the Choreography Task MAY be repeated. There are two types of internal markers (see Figure 11.12):

- A Choreography Task MAY have only one of the three (3) markers at one time.
◆ The marker for a **Choreography Task** that is a standard *loop* MUST be a small line with an arrowhead that curls back upon itself. The **loopType** of the **Choreography Task** MUST be **Standard**.

◆ The marker for a **Choreography Task** that is parallel *multi-instance* MUST be a set of three vertical lines. The **loopType** of the **Choreography Task** MUST be **MultiInstanceParallel**.

◆ The marker for a **Choreography Task** that is sequential *multi-instance* MUST be a set of three horizontal lines. The **loopType** of the **Choreography Task** MUST be **MultiInstanceSequential**.

The marker that is present MUST be centered at the bottom of the **Task Name Band** of the shape.

---

**Figure 11.12 - Choreography Task Markers**

**Figure 11.13 - The Collaboration view of a looping Choreography Task**
There are situations when a Participant for a Choreography Task is actually a multi-instance Participant. A multi-instance Participant represents a situation where there are more than one possible related Participants (PartnerRoles/PartnerEntities) that might be involved in the Choreography. For example, in a Choreography that involves the shipping of a product, there can be more than one type of shipper used, depending on the destination. When a Participant in a Choreography contains multiple instances, then a multi-instance marker will be added to the Participant Band for that Participant (see Figure 11.15).

- The marker for a Choreography Task that is multi-instance MUST be a set of three vertical lines.
- The marker that is present MUST be centered at the bottom of the Participant Band of the shape.

The width of the Participant Band will be expanded to contain both the name of the Participant and the multi-instance marker.

Figure 11.14 - The Collaboration view of a Parallel Multi-Instance Choreography Task

Figure 11.15 - A Choreography Task with a multiple Participant
The **Choreography Task** element inherits the attributes and model associations of **Choreography Activity** (see Table 11.1). Table 11.2 presents the additional model associations of the **Choreography Task** element.

### Table 11.2 – Choreography Task Model Associations

<table>
<thead>
<tr>

<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageFlowRef: Message Flow [1..*]</td>
<td>Although not graphical represented, <strong>Choreography Task</strong> contain one (1) or more <strong>Message Flows</strong> that represent the interaction(s) between the <strong>Participants</strong> referenced by the <strong>Choreography Task</strong>.</td>
</tr>
</tbody>
</table>

### 11.4.2 Sub-Choreography

A **Sub-Choreography** is a compound **Activity** in that it has detail that is defined as a flow of other **Activities**, in this case, a **Choreography**. Each **Sub-Choreography** involves two (2) or more **Participants**. The name of the **Sub-Choreography** and each of the **Participants** are all displayed in the different bands that make up the shape’s graphical notation. There are two (2) or more **Participant Bands** and one **Sub-Process Name Band**.

The **Sub-Choreography** can be in a collapsed view that hides its details (see Figure 11.17) or a **Sub-Choreography** can be expanded to show its details (a **Choreography Process**) within the **Choreography Process** in which it is contained (see Figure 11.19). In the collapsed form, the **Sub-Process** object uses a marker to distinguish it as a **Sub-Choreography**, rather than a **Choreography Task**.

The **Sub-Process** marker MUST be a small square with a plus sign (+) inside. The square MUST be positioned at the bottom center of the **Sub-Process Name Band** within the shape.

- **The Participant Band** of the **Participant** that does not initiate the interaction MUST be shaded with a light fill.
Figure 11.17 - A Sub-Choreography

Figure 11.18 shows an example of a potential Collaboration view of the above Sub-Choreography.

Figure 11.18 - A Collaboration view of a Sub-Choreography
Figure 11.19 shows an example of an expanded Sub-Choreography.

![Choreography Diagram](image)

**Figure 11.19 - An expanded Sub-Choreography**

Figure 11.20 shows an example of a potential **Collaboration** view of the above **Sub-Choreography**.

![Collaboration Diagram](image)

**Figure 11.20 - A Collaboration view of an expanded Sub-Choreography**
The Parent Sub-Choreography (Expanded)

The Choreography Activity shares the same shape as a Sub-Process or any other BPMN Activity, which is in this state.

- A Sub-Choreography is a rounded corner rectangle that MUST be drawn with a single thin line.
- The use of text, color, size, and lines for a Sub-Choreography MUST follow the rules defined in Section “Use of Text, Color, Size, and Lines in a Diagram” on page 41.

The three (3) or more partitions in the Sub-Choreography shape provide the distinction between this type of Task and an Orchestration Sub-Process (in a traditional BPMN diagram).

It is possible for a Sub-Choreography to involve more than two (2) Participants. In this case, an additional Participant Band will be added to the shape for each additional Participant (see Figure 11.21). The ordering and position of the Participant Band (either in the upper or lower positions) is up to the modeler or modeling tool. In addition, any Participant Band beyond the first two optional; it is displayed at the discretion of the modeler or modeling tool. However, each Participant Band that is added MUST be added to the upper and lower sections of the Sub-Choreography in an alternative manner.

- The marker that is present MUST be centered at the bottom of the Sub-Process Name Band of the shape.

![Figure 11.21 - Sub-Choreography (Collapsed) with More than Two (2) Participants](image)

As with a standard Orchestration Sub-Process, the Sub-Choreography MAY have internal markers to show how the Sub-Choreography MAY be repeated. There are two types of internal markers (see Figure 11.22):

- A Sub-Choreography MAY have only one of the three (3) markers at one time.
- The marker for a Sub-Choreography that is a standard loop MUST be a small line with an arrowhead that curls back upon itself. The loopType of the Sub-Choreography MUST be Standard.
- The marker for a Sub-Choreography that is parallel multi-instance MUST be a set of three vertical lines. The loopType of the Sub-Choreography MUST be MultiInstanceParallel.
- The marker for a Sub-Choreography that is sequential multi-instance MUST be a set of three horizontal lines. The loopType of the Sub-Choreography MUST be MultiInstanceSequential.
- The marker that is present MUST be centered at the bottom of the Sub-Process Name Band of the shape.
There are situations when a Participant for a Sub-Choreography is actually a multi-instance Participant. A multi-instance Participant represents a situation where there are more than one possible related Participants (PartnerRoles/PartnerEntities) that can be involved in the Choreography. For example, in a Choreography that involves the shipping of a product, there can be more than one type of shipper used, depending on the destination. When a Participant in a Choreography contains multiple instances, then a multi-instance marker will be added to the Participant Band for that Participant (see Figure 11.23).

- The marker for a Sub-Choreography that is multi-instance MUST be a set of three vertical lines.
- The marker that is present MUST be centered at the bottom of the Participant Band of the shape.
- The width of the Participant Band will be expanded to contain both the name of the Participant and the multi-instance marker.

This includes Compensation Event Sub-Processes (contained within a Sub-Choreography) as well as the external Compensation Activity connected through an Association.

The Sub-Choreography element inherits the attributes and model associations of Choreography Activity (see Table 11.1) and FlowElementsContainer (see Table 8.45). Table 11.3 presents the additional model associations of the GlobalChoreographyTask element:

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>artifacts: Artifact [0..*]</td>
<td>This attribute provides the list of Artifacts that are contained within the Sub-Choreography.</td>
</tr>
</tbody>
</table>
11.4.3 Call Choreography

A Call Choreography identifies a point in the Process where a global Choreography or a Global Choreography Task is used. The Call Choreography acts as a place holder for the inclusion of the Choreography element it is calling. This pre-defined called Choreography element becomes a part of the definition of the parent Choreography.

A Call Choreography object shares the same shape as the Choreography Task and Sub-Choreography, which is a rectangle that has rounded corners, two (2) or more Participant Bands, and an Activity Name Band. However, the target of what the Choreography Activity calls will determine the details of its shape.

◆ If the Call Choreography calls a Global Choreography Task, then the shape will be the same as a Choreography Task, but the boundary of the shape will MUST have a thick line (see Figure 11.24)

◆ If the Call Choreography calls a Choreography, then there are two (2) options:
  ◆ The details of the called Choreography can be hidden and the shape will be the same as a collapsed Sub-Choreography, but the boundary of the shape MUST have a thick line (see Figure 11.25).
  ◆ The details of the called Choreography can be shown and the shape will be the same as an expanded Sub-Choreography, but the boundary of the shape MUST have a thick line (see Figure 11.26).

Figure 11.24 - A Call Choreography calling a Global Choreography Task

Figure 11.25 - A Call Choreography calling a Choreography (Collapsed)
Figure 11.26 - A Call Choreography calling a Choreography (expanded)

Figure 11.27 - The Call Choreography class diagram

The Call Choreography element inherits the attributes and model associations of ChoreographyActivity (see Figure 11.27 and Table 11.1). Table 11.4 presents the additional model associations of the Call Choreography element.
11.4.4 Global Choreography Task

A GlobalChoreographyTask is a reusable, atomic Choreography Task definition that can be called from within any Choreography by a Call Choreography.

The GlobalChoreographyTask element inherits the attributes and model associations of Collaboration (see Table 9.1), through its relationship to Choreography. Table 11.5 presents the additional model associations of the GlobalChoreographyTask element.

Table 11.4 – Call Choreography Model Associations

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description/Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>calledChoreographyRef:</td>
<td>The element to be called, which will be either a Choreography or a GlobalChoreographyTask.</td>
</tr>
<tr>
<td>CallableElement [0..1]</td>
<td></td>
</tr>
<tr>
<td>participantAssociations:</td>
<td>Specifies how Participants in a nested Choreography or GlobalChoreographyTask match up with the Participants in the Choreography referenced by the Call Choreography.</td>
</tr>
<tr>
<td>ParticipantAssociation [0..*]</td>
<td></td>
</tr>
</tbody>
</table>

A GlobalChoreographyTask is a restricted type of Choreography, it is an "empty Choreography."

◆ A GlobalChoreographyTask MUST NOT contain any Flow Elements.

Since a GlobalChoreographyTask does not have any Flow Elements, it does not require MessageFlowAssociations, ParticipantAssociations, ConversationAssociations, or Artifacts. It is basically a set of Participants and Message Flows intended for reuse.

11.4.5 Looping Activities

Both Sub-Choreographies can have standard loops and multi-instances. Examples of Choreography Activities with the appropriate markers can be seen in Figure 11.12 and Figure 11.22.

11.4.6 The Sequencing of Activities

There are constraints on how Choreography Activities can be sequenced (through Sequence Flows) in a Choreography. These constraints are due to the limited visibility of the Participants, which only know of the progress of the Choreography by the Messages that occur. When a Participant sends or receives a Message, then that Participant knows exactly how far the Choreography has progressed. This means that the ordering of Choreography Activities need to take into account when the Participants send or receive Messages so that they Participants are NOT REQUIRED to guess about when it is their turn to send a Message.
The basic rule of **Choreography Activity** sequencing is this:

- The *Initiator* of a **Choreography Activity** MUST have been involved (as *Initiator* or *Receiver*) in the previous **Choreography Activity**.

Of course, the first **Choreography Activity** in a **Choreography** does not have this constraint.

Figure 11.28 shows a sequence of two (2) **Choreography Activities** that follow this constraint. “Participant B” is the *Initiator* of “Choreography Task 2” after being the *Receiver* in “Choreography Task 1.” While there is no requirement that “Participant B” sends the *Message* immediately, since there can be internal work that the *Participant* needs to do prior to the *Message*. But in this situation there is no ambiguity that “Participant B” will be the *Initiator* of the next **Choreography Task**. “Participant C” does not know exactly when the *Message* will arrive from “Participant B,” but “Participant C” knows that one will arrive and there are not any additional requirements on the *Participant* until the *Message* arrives.

![Figure 11.28 - A valid sequence of Choreography Activities](image)

Naturally, the sequence of **Choreography Activities** shown in Figure 11.28, above can be expanded into a **Collaboration** diagram to show how the sequence can be enforced. Figure 11.29 shows the corresponding **Collaboration**. The diagram shows how the **Activities** within the individual **Pools** fit with the design of the **Choreography**.
When determining a valid sequence of Choreography Tasks, it is important to consider the type of Choreography Tasks that are being used. A single Choreography Task can be used for one (1) or two (2) Messages. Most of the time there will be one (1) or two (2) Messages for a Choreography Task. Figure 11.30 shows a sequence of Choreography Tasks, the first one being a two-way interaction, where the initiator sends a Message and gets a response from the other Participant.

Figure 11.29 - The corresponding Collaboration for a valid Choreography sequence

Figure 11.30 - A valid sequence of Choreography Activities with a two-way Activity
Figure 11.31 shows the corresponding **Collaboration** and how the two **Choreography Tasks** are reflected in the **Processes** within the **Pools**. The **Choreography Task** that has two **Messages** is reflected by three **Process Tasks**. Usually in these cases, the initiating Participant will use a single **Activity** to handle both the sending and receiving of the **Messages**. A **BPMN Service Task** can be used for this purpose and these types of **Tasks** are often referred to as “request-response” **Tasks** for **Choreography** modelers.

![Figure 11.31 - The corresponding Collaboration for a valid Choreography sequence with a two-way Activity](image)

Figure 11.32 shows how a sequence of **Choreography Activities** can be designed that would be invalid in the sense that an **Initiating Participant** would not know when the appropriate time would be to send a **Message**. In this example, “Participant A” is scheduled to send a **Message** to “Participant C” after “Participant B” sends a **Message** to “Participant C.” However, “Participant A” will not know when the **Message** from “Participant B” has been sent. So, there is no way to enforce the sequence that is modeled in the **Choreography**.
Figure 11.32 - An invalid sequence of Choreography Activities

Figure 11.33 shows the Collaboration view of the above Choreography diagram. It becomes clear that “Participant A” will not know the appropriate time to send Message “M3” to “Participant C.” If the Message is sent too soon, then “Participant C” will not be prepared to receive it. Thus, as a Choreography, the model in Figure 11.32, above, cannot be enforced.

Figure 11.33 - The corresponding Collaboration for an invalid Choreography sequence
11.5 Events

11.5.1 Start Events

Start Events provide the graphical marker for the start of a Choreography. They are used much in the same way as they are used for a Process (see “Start Event” on page 245).

This table shows how the types of Start Events are applied to Choreography.

<table>
<thead>
<tr>
<th>Type of Event</th>
<th>Usage in Choreography?</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Yes. This is really just a graphical marker since the arrival of the first Message in the Choreography is really the Trigger for the Choreography. Sub-Processes, however, we should look at. The Parent Process can be considered the trigger.</td>
</tr>
<tr>
<td>Message</td>
<td>No. A Message Start Event, in a stand-alone Choreography, has no way to show who the senders or receivers of the Message should be. A Choreography Task should be used instead. Thus, a None Start Event should be used as a graphical marker for the “start” of the Choreography.</td>
</tr>
<tr>
<td>Timer</td>
<td>Yes. All Participants have to have an agreement to the approximate time.</td>
</tr>
<tr>
<td>Escalation</td>
<td>No. An Escalation is only visible to a single Participant. That Participant will have to send a Message to the other Participants.</td>
</tr>
<tr>
<td>Error</td>
<td>No. An Error is only visible to a single Participant. That Participant will have to send a Message to the other Participants.</td>
</tr>
<tr>
<td>Compensation</td>
<td>No. Compensation is handled within a single Participant (an orchestration Process).</td>
</tr>
<tr>
<td>Conditional</td>
<td>Yes. This is actually determined internal to Participant, but then the other Participants know this has happened based the first interaction that follows.</td>
</tr>
<tr>
<td>Signal</td>
<td>Yes. The source of the Signal is NOT REQUIRED (and might not even be a Participant in the Choreography). There are no specific recipients of a Signal. All Participants of the Choreography (to comply) MUST be able to see the Signal.</td>
</tr>
<tr>
<td>Multiple</td>
<td>Yes. But they can only be Multiple Signals or Timers. As in Orchestration, this acts like an OR. Any one of the incoming Signals will Trigger the Choreography. Any Signal that follows would create a separate instance of the Choreography.</td>
</tr>
</tbody>
</table>

11.5.2 Intermediate Events

Table 11.7 - Use of Intermediate Events in Choreography

<table>
<thead>
<tr>
<th>Type of Event</th>
<th>Usage in Choreography?</th>
</tr>
</thead>
</table>
Table 11.7 - Use of Intermediate Events in Choreography

<table>
<thead>
<tr>
<th>None: in Normal Flow</th>
<th>Yes. However, this really doesn’t have much meaning other than just documenting that a specific point has been reached in the <strong>Choreography</strong>. There would be no <strong>Message</strong> exchange or any delay in the <strong>Choreography</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>None: Attached to Activity boundary</td>
<td>No. There would be no way for <strong>Participants</strong> to know when the <strong>Activity</strong> should be interrupted.</td>
</tr>
<tr>
<td>Message: in Normal Flow</td>
<td><strong>No.</strong> A <strong>Message Intermediate Event</strong>, in a stand-alone <strong>Choreography</strong>, has no way to show who the senders or receivers of the <strong>Message</strong> should be. A <strong>Choreography Task</strong> should be used instead. Also, would the <strong>Event</strong> be a <strong>Catch</strong> or a <strong>Throw</strong>?</td>
</tr>
<tr>
<td>Message: Attached to Activity boundary</td>
<td><strong>Yes.</strong> Only for <strong>Choreography Tasks</strong>. The Intermediate Event has to be attached to the <strong>Participant Band</strong> of the receiver of the <strong>Message</strong> (since it is a catch Event). The sender of the message has to be the other <strong>Participant</strong> of the <strong>Choreography Task</strong>.</td>
</tr>
<tr>
<td>Message: Use in Event Gateway</td>
<td><strong>No.</strong> A <strong>Message Intermediate Event</strong>, in a stand-alone <strong>Choreography</strong>, has no way to show who the senders or receivers of the <strong>Message</strong> should be. A <strong>Choreography Task</strong> should be used instead.</td>
</tr>
</tbody>
</table>
| Timer: in Normal Flow | **Yes.** Time is not precise in **Choreography**. It is established by the last visible **Choreography Activity**. The **Participants** involved in the Choreography Activity that immediately precedes will have a rough approximation of the time—there will be no exact synchronization.  

For relative timers: Only the **Participants** involved in the Choreography Activity that immediately precedes the Event would know the time. The sender of the Choreography Activity that immediately follows the timer MUST be involved in the Choreography Activity that immediately precedes the timer.  

For absolute timers (full time/date): All **Participants** would know the time. There does not have to be a relationship between the **Participants** of the Choreography Activities that are on either side the timer.  

The sender of the Choreography Activity that immediately follows the timer is the **Participant** that enforces the timer. |
Timer: Attached to Activity boundary | Yes. Time is not exact in this case. It is established by the last visible Event. All Participants will have a rough approximation of the time—there will be no exact synchronization. This includes both interrupting and escalation Events. The Participants of the Choreography Activity that has the attached timer all enforce the timer. For relative timers: They all have to be involved in the Choreography Activity that immediately precedes the Activity with the attached timer. For absolute timers (full time/date): All Participants would know the time. They all have to be involved in the Choreography Activity that immediately precedes the Activity with the attached timer.

Timer: Used in Event Gateway | Yes. See Event-Based Gateway below.

Error: Attached to Activity boundary | No. An Error is only visible to a single Participant. That Participant will have to send a Message to the other Participants.

Escalation: Used in Normal Flow | No. An Escalation is only visible to a single Participant. That Participant will have to send a Message to the other Participants.

Escalation: Attached to Activity boundary | No. An Escalation is only visible to a single Participant. That Participant will have to send a Message to the other Participants.

Cancel: in Normal Flow | No. These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the Cancel.

Cancel: Attached to Activity boundary | Yes. These are Catch Events. As with a Message Event, they would be attached to the Choreography Activity on the Participant Band that is receiving the Cancel. These would only be interrupting Events.

Compensation: in Normal Flow | No. These are Throw Events. As with a Message, there would be no indicator as to who is the source of the Cancel.

Compensation: Attached to Activity boundary | Yes. These are Catch Events. As with a Message Event, they would be attached to the Choreography Activity on the Participant Band that is receiving the Cancel.

Conditional: in Normal Flow | Yes. This is a delay that waits for a change in data to trigger the Event. The data are to be visible to the Participants as it was data of a previously sent Message.

Conditional: Attached to Activity boundary | Yes. This is an interruption that waits for a change in data to trigger the Event. The data are to be visible to the Participants as it was data of a previously sent Message.

Conditional: Used in Event Gateway | Yes. This is a delay that waits for a change in data to trigger the Event. The data are to be visible to the Participants as it was data of a previously sent Message.
Table 11.7 - Use of Intermediate Events in Choreography

<table>
<thead>
<tr>
<th>Event</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Link: in Normal Flow</td>
<td>Yes. These types of <strong>Events</strong> merely create a virtual <strong>Sequence Flows</strong>. Thus, as long as a <strong>Sequence Flow</strong> between two elements is valid (and within a <strong>Choreography Process</strong> level), then a pair of <strong>Link Events</strong> can interrupt that <strong>Sequence Flow</strong>.</td>
</tr>
<tr>
<td>Signal: in Normal Flow</td>
<td>Yes. Only <strong>Catch Events</strong> can be used. For <strong>Throw Signal Events</strong>, there would be no indicator of who is the source <strong>Participant</strong>. This would be a delay in the <strong>Choreography</strong> that waits for the <strong>Signal</strong>. The source of the <strong>Signal</strong> is NOT REQUIRED (and might not even be a <strong>Participant</strong> in the <strong>Choreography</strong>). There are no specific recipients of a <strong>Signal</strong>. All <strong>Participants</strong> of the <strong>Choreography</strong> (to comply) MUST be able to see the <strong>Signal</strong>.</td>
</tr>
<tr>
<td>Signal: Attached to Activity boundary</td>
<td>Yes. These are <strong>Catch Events</strong>. This would be an interruption in the <strong>Choreography</strong> that waits for the <strong>Signal</strong>. The source of the <strong>Signal</strong> is NOT REQUIRED (and might not even be a <strong>Participant</strong> in the <strong>Choreography</strong>). There are no specific recipients of a <strong>Signal</strong>. All <strong>Participants</strong> of the <strong>Choreography</strong> (to comply) MUST be able to see the <strong>Signal</strong>. This <strong>Event</strong> MUST NOT be attached to a <strong>Participant Band</strong> or this would suggest that that <strong>Participant</strong> is a specific recipient of the <strong>Signal</strong>.</td>
</tr>
<tr>
<td>Signal: Used in Event Gateway</td>
<td>Yes. These are <strong>Catch Events</strong>. This would be a delay in the <strong>Choreography</strong> that waits for the <strong>Signal</strong>. The source of the <strong>Signal</strong> is NOT REQUIRED (and might not even be a <strong>Participant</strong> in the <strong>Choreography</strong>). There are no specific recipients of a <strong>Signal</strong>. All <strong>Participants</strong> of the <strong>Choreography</strong> (to comply) MUST be able to see the <strong>Signal</strong>.</td>
</tr>
<tr>
<td>Multiple: in Normal Flow</td>
<td>Yes. But they can only be a collection of valid <strong>Catch Events</strong>. As in <strong>Orchestration</strong>, this acts like an OR. Any one of the incoming triggers will continue the <strong>Choreography</strong>.</td>
</tr>
<tr>
<td>Multiple: Attached to Activity Boundary</td>
<td>Yes. But they can only be a collection of valid <strong>Catch Events</strong>. As in <strong>Orchestration</strong>, this acts like an OR. Any one of the incoming triggers will interrupt the <strong>Choreography Activity</strong>.</td>
</tr>
</tbody>
</table>
11.5.3 End Events

End Events provide a graphical marker for the end of a path within the Choreography.

Table 11.8 – Use of End Events in Choreography

<table>
<thead>
<tr>
<th>Type of Event</th>
<th>Usage in Choreography?</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Yes. This is really just a graphical marker since the sending of the previous Message in the Choreography is really the end of the Choreography. The Participants of the Choreography would understand that they would not expect any further Message at that point.</td>
</tr>
<tr>
<td>Message</td>
<td>No. A Message End Event, in a stand-alone Choreography, has no way to show who the senders or receivers of the Message should be. A Choreography Task should be used instead. Thus, a None End Event should be used as a graphical marker for the “end” of the Choreography</td>
</tr>
<tr>
<td>Error</td>
<td>No. These are Throw Events and there would be no way to indicate the Participant that is the source of the Error.</td>
</tr>
<tr>
<td>Escalation</td>
<td>No. These are Throw Events and there would be no way to indicate the Participant that is the source of the Escalation.</td>
</tr>
<tr>
<td>Cancel</td>
<td>No. These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the Cancel.</td>
</tr>
<tr>
<td>Compensation</td>
<td>No. These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the compensation.</td>
</tr>
<tr>
<td>Signal</td>
<td>No. These are Throw Events. As with a Message Event, there would be no indicator as to who is the source of the Signal.</td>
</tr>
<tr>
<td>Multiple</td>
<td>No. Since there are no valid End Event Results (Terminate doesn’t count) in Choreography, there cannot be multiple of them.</td>
</tr>
<tr>
<td>Terminate</td>
<td>Yes. However, there would be no specific ability to terminate the Choreography, since there is no controlling system. In this case, all Participants in the Choreography would understand that when the Terminate End Event is reached (actually when the Message that precedes it occurs), then no further messages will be expected in the Choreography, even if there were parallel paths. The use of the Terminate End Event really only works when there are only two (2) Participants. If there are more than two (2) Participants, then any Participant that was not involved in the last Choreography Task would not necessarily know that the Terminate End Event had been reached.</td>
</tr>
</tbody>
</table>
11.6 Gateways

In an Orchestration Process, Gateways are used to create alternative and/or parallel paths for that Process. Choreography has the same requirement of alternative and parallel paths. That is, interactions between Participants can happen in sequence, in parallel, or through exclusive selection. While the paths of Choreography follow the same basic patterns as that of an Orchestration Process, the lack of a central mechanism to maintain data visibility, and that there is no central evaluation, there are constraints as to how the Gateways are used in conjunction with the Choreography Activities that precede and follow the Gateways. These constraints are an extension of the basic sequencing constraints that was defined on page 345. The six (6) sections that follow will define how the types of Gateways are used in Choreography.

11.6.1 Exclusive Gateway

Exclusive Gateways (Decisions) are used to create alternative paths within a Process or a Choreography. For details of how Exclusive Gateways are used within an Orchestration Process see page 298.

Exclusive Gateways are used in Choreography, but they are constrained by the lack of a central mechanism to store the data that will be used in the Condition expressions of the Gateway’s outgoing Sequence Flows. Choreographies MAY contain natural language descriptions of the Gateway’s Conditions to document the alternative paths of the Choreography (e.g., “large orders” will go down one path while “small orders” will go down another path), but such Choreographies would be underspecified and would not be enforceable. To create an enforceable Choreography, the Gateway Conditions MUST be formal Condition Expressions; however:

◆ The data used for Gateway Conditions MUST have been in a Message that was sent prior to (upstream from) the Gateway.

◆ More specifically, all Participants that are directly affected by the Gateway MUST have either sent or received the Message(s) that contained the data used in the Conditions.

◆ Furthermore, all these Participants MUST have the same understanding of the data. That is, the actual values of the data cannot selectively change after a Participant has seen a Message. Changes to data during the course of the Choreography MUST be visible to all the Participants affected by the Gateway.

These constraints ensure that the Participants in the Choreography understand the basis (the actual value of the data) for the decision behind the Gateway.

One (1) or more Participants will actually “control” the Gateway decision; that is, these Participants make the decision through the internal Orchestration Processes. The decision is manifested by the particular Message that occurs in the Choreography after the Gateway. This Message is the initiating Message of a Choreography Activity that follows the Gateway. Thus, only the Participants that are the initiators of the Messages that follow the Gateway are the ones that control the decision. This means that:

◆ The initiating Participants of the Choreography Activities that follow the Gateway MUST have sent or received the Message that provided the data upon which the decision is made.

◆ The Message that provides the data for the Gateway MAY be in any Choreography Activity prior to the Gateway (i.e., it does not have to immediately precede Gateway).
Figure 11.34 - An example of the Exclusive Gateway

Figure 11.35 shows the Collaboration that demonstrates how the above Choreography that includes an Exclusive Gateway can be enforced.
Figure 11.35 - The relationship of Choreography Activity Participants across the sides of the Exclusive Gateway shown through a Collaboration

Usually, the initiators for the Choreography Activities that follow the Gateway will be the same Participant. That is, there is only one (1) Participant controlling the decision. Often, the receivers of the initiating Message for those Choreography Activities will be the same Participant. However, it is possible that there could be different Participants receiving the initiating Message for each Choreography Activity (see Figure 11.36).
This configuration can only be valid if all the Participants in the Choreography Activities that follow the Gateway have seen the data upon which the decision is made. If either “Participant B” or “Participant C” had not sent or receive a Message with the appropriate data, then that Participant would not be able to know if they are suppose to receive a Message at that point in the Choreography. There is also the assumption that the value of the data is consistent from the point of view of all Participants.

Figure 11.37 displays the corresponding Collaboration view of the above Choreography Exclusive Gateway configuration.
The REQUIRED execution behavior of the Gateway and associated Choreography Activities are enforced through the Business Processes of the Participants as follows:

- Each Choreography Activity and the Sequence Flow connections are reflected in each Participant Process.
- The Gateway is reflected in the Process of each Participant Process that is an initiator of Choreography Activities that follow the Gateway.
- For the receivers in Choreography Activities that follow the Gateway, an Event-Based Gateway is used to consume the associated Message (sent as an outcome of the Gateway). When a Participant is the receiver of more than one of the alternative Messages, the corresponding receives follow the Event-Based Gateway. If the Participant is the receiver of only one such Message, that is also consumed through a receive following the Event-Based Gateway. This is because the Participant Process does not know whether it will receive a Message (since the Gateway entails a choice of outcomes).
11.6.2 Event-Based Gateway

As described above, the Event-Based Gateway represents a branching point in the Process where the alternatives are based on Events that occur at that point in the Process, rather than the evaluation of expressions using Process data. For details of how Event-Based Gateways are used within an Orchestration Process see Section “Event-Based Gateway” on page 305.

These Gateways are used in Choreography when the data used to make the decision is only visible to the internal Processes of one Participant. That is, there has been no Message sent within the Choreography that would expose the data used to make the decision. Thus, the only way that the other Participants can be aware of the results of the decision is by the particular Message that arrives next.

- On the right side of the Gateway: either
  - The senders MUST to be the same; or
  - The receivers MUST to be the same
    - After the first Choreography Activity occurs, the other Choreography Activities for the Gateway MUST NOT occur.

- Message Intermediate Events MUST NOT be used in the Event-Based Gateway.

- Timer Intermediate Events MAY be used, but they restrict the participation in the Gateway.
  - For relative timers: All Participants on the right side of the Gateway MUST be involved in the Choreography Activity that immediately precedes the Gateway.
  - For absolute timers (full time/date): All Participants on the right side of the Gateway MUST be involved in the Choreography Activity that immediately precedes the Gateway.

- Signal Intermediate Events MAY be used (they are visible to all Participants)
- No other types of Intermediate Events are allowed.

![Figure 11.38 - An example of an Event Gateway](image)

Figure 11.38 displays the corresponding Collaboration view of the above Choreography Event Gateway configuration.
The REQUIRED execution behavior of the Event-Based Gateway and associated Choreography Activities are enforced through the Business Processes of the Participants as follows:

- Each Choreography Activity and the Sequence Flow connections is reflected in each Participant Process.

- If the senders following the Gateway are the same, the Event-Based Gateway is reflected as an Exclusive Gateway in that Participant’s Process. This is because the choice of which Message to send is determined by the same Participant. If the senders are different, sending occurs through different Processes.

- If the receivers are the same, the senders can be the same or different. In this case, the Event-Based Gateway is reflected in the receiver’s Process, with the different Message receives following the Gateway.

- If the receivers are different, the senders need to be the same. The Event-Based Gateway is reflected for different receiver Processes such that the respective receive follows the Gateway. A time-out can be used to ensure that the Gateway does not wait indefinitely.
11.6.3 Inclusive Gateway

Inclusive Gateways are used for modeling points of synchronization of a number of branches, not all of which are active, after which one or more alternative branches are chosen within a Choreography flow. For example, one of more branches MAY be activated upstream, in parallel, depending on the nature of goods in an order (e.g., large orders, fragile goods orders, orders belonging to pre-existing shipment contracts), and these are subsequently merged. The point of merge results in one or more risk mitigating outcomes (e.g., special insurance protection needed, special packaging needed, and different container categories needed). Inclusive Gateways are also used within an Orchestration Process see page 300.

Like Exclusive Gateways, Inclusive Gateways are used in a Choreography, but they are constrained by the lack of a central mechanism to store the data that will be used in the Condition expressions of the Gateway’s outgoing Sequence Flows. Choreographies MAY contain natural language descriptions of the Gateway’s Conditions to document the one more alternative paths of the Choreography (e.g., “special insurance protection needed,” “special packaging needed,” and different “container category needed”), but such Choreographies would be underspecified and would not be enforceable. To create an enforceable Choreography, the Gateway Conditions MUST be formal Condition Expressions. In general the following rules apply for the Expressions:

Like the enforceability of the Exclusive Gateway, the Inclusive Gateway in a Choreography requires that the data in the Expressions of the outgoing Sequence Flows of the Gateway be available to the initiators of the Choreography Activities of outgoing Sequence Flows. This means that the initiators of these Choreography Activities should also be senders or receivers of Messages in Choreography Activities immediately preceding the Gateway. The major difference, however, is that the synchronizing behavior of the Inclusive Gateway can only be enforced through one participant. Hence, the rules for enforceability are as follows:

- The data used for Gateway Conditions MUST have been in a Message that was sent prior to (upstream from) the Gateway.
- More specifically, all Participants that are directly affected by the Gateway MUST have either sent or received the Message(s) that contained the data used in the Conditions.
- Furthermore, all these Participants MUST have the same understanding of the data. That is, the actual values of the data cannot selectively change after a Participant has seen a Message. Changes to data during the course of the Choreography MUST be visible to all the Participants affected by the Gateway.
- Merge: In order to enforce the synchronizing merge of the Gateway, the sender of the Choreography Activity after the Gateway MUST participate in the Gateway immediately preceding the Gateway. This ensures that the merge can be enforced. (This relies on the assumption of logical atomicity of a Choreography Activity, otherwise the rule would require that all receivers are the same so that the Gateway is enforced in the receiver’s Process only).
- Split: In order to enforce the split side of the Gateway, the initiators of all Choreography Activities immediately following the Gateway MUST be the same as the common sender or receiver of Choreography Activities preceding the Gateway. The sender(s) of all the Choreography Activities after the Gateway MUST be involved in all the Choreography Activities that immediately precede the Gateway.

Figure 11.40 shows an example of a Choreography with an Inclusive Gateway. The Gateway is enforced in the corresponding Business Processes of the Participants involved. For the merge behavior to be enforced, the initiator of Choreography Activities immediately following the Gateway participates in the Choreography Activities immediately preceding the Gateway.
Figure 11.40 - An example of a Choreography Inclusive Gateway configuration
Figure 11.41 - The corresponding Collaboration view of the above Choreography Inclusive Gateway configuration

Figure 11.42, a variation of Figure 11.40 above, shows an example of a Choreography illustrating the enforcement of the split behavior of the Inclusive Gateway. For the split behavior to be enforced, the initiators of Choreography Activities immediately following the Gateway and the receiver of Choreography Activities immediately preceding the Gateway are the same Participant (i.e., A).
Figure 11.42 - An example of a Choreography Inclusive Gateway configuration
Figure 11.43 - The corresponding Collaboration view of the above Choreography Inclusive Gateway configuration
Figure 11.44 - Another example of a Choreography Inclusive Gateway configuration
Figure 11.45 - The corresponding Collaboration view of the above Choreography Inclusive Gateway configuration
11.6.4 Parallel Gateway

Parallel Gateways are used to create paths and are performed at the same time, within a Choreography flow. For details of how Parallel Gateways are used within an Orchestration Process see page 301.

Since there is no conditionality for these Gateways, they are available as-is in Choreography. They create parallel paths of the Choreography that all Participants are aware of.

- The sender(s) of all the Activities after the Gateway MUST be involved in all the Activities that immediately precede the Gateway.
- If there is a chain of Gateways with no Choreography Activities in between, the Choreography Activity that precedes the chain satisfies the above constraint.

Figure 11.46 shows the relationship of Choreography Activity Participants across the sides of the Parallel Gateway.

Figure 11.47 shows the corresponding Collaboration view of the above Choreography Parallel Gateway configuration.
The REQUIRED execution behavior of the **Parallel Gateway** and associated **Choreography Activities** are enforced through the **Business Processes** of the **Participants** as follows:

- Each **Choreography Activity** and the **Sequence Flow** connections is reflected in each **Participant Process**.
- If the senders following the **Parallel Gateway** are the same, a **Parallel Gateway** is reflected in the sender’s **Process** followed by **Message** sending actions to the corresponding receivers.
- If the senders are different, the **Parallel Gateway** is manifested by **Sequence Flows** followed by the sending action in each **Process**.

---

**Figure 11.47 - The corresponding Collaboration view of the above Choreography Parallel Gateway configuration**
11.6.5 Complex Gateway

Complex Gateways can model partial merges in Business Processes where when some but not all of a set of preceding branches complete, the Gateway fires. This can be considered the discriminator/n-of-m join pattern and is not supported through the inclusive OR merge since it is not concerned with sets of branches, but rather branches which have tokens. Applied in Choreographies, Complex Gateways can model tendering and information canvassing use cases where requests are sent to participants who respond at different times.

Consider an e-tender which sends a request for quote to multiple service providers (e.g., warehouse storage) in a marketplace. The e-tender Process sends out requests to each service provider and anticipates their response through three Choreography Activities. The response branches merge at a Complex Gateway to model the requirement that when 66% responses have arrived, an assessment of the tender can proceed. The assessment occurs after the Complex Gateway. If the assessment reports that the reserve amount indicated by the customer cannot be met, a new iteration of the tender is made. A key issue is to ensure that the responses should not be mixed across tender iterations. A Terminate End Event ensures that all Activities are terminated, when a tender has been successful.

![Figure 11.48 - An example of a Choreography Complex Gateway configuration](http://www.workflowpatterns.com/patterns/control/advanced_branching/wcp9.php)
11.6.6 Chaining Gateways

It is possible to chain Gateways. This means that a modeler can sequence two (2) or more Gateways without any intervening Choreography Activities, however the constraints on what participants can appear before and after the chain MUST be observed.

11.7 Choreography within Collaboration

11.7.1 Participants

Participants are used in both Collaborations and Choreographies.
11.7.2 Swimlanes

Swimlanes, both Pools and Lanes, are not used in Choreographies. Pools are used exclusively in Collaborations (see page 115). Participants, which can be associated to Pools, however, are used in the Participant Bands of Choreography Tasks (see page 333) and Sub-Choreographies (see page 338). Pools can be used with Choreography diagrams when in the context of a Collaboration diagram (see page 372).

Lanes are not used in Choreography diagrams since Lanes are sub-partitions of a Pool and Choreographies are placed in between the Pools (if used in a Collaboration).

Figure 11.50 shows an example of a Choreography Process combined with Black Box Pools.

![Diagram](image)

**Figure 11.50 - An example of a Choreography Process combined with Black Box Pools**

12 BPMN Notation and Diagrams

12.1 BPMN Diagram Interchange (BPMN DI)

12.1.1 Scope

This chapter specifies the meta-model and schema for BPMN 2.0 Diagram Interchange (BPMN DI). The BPMN DI is meant to facilitate interchange of BPMN diagrams between tools rather than being used for internal diagram representation by the tools. The simplest interchange approach to ensure the unambiguous rendering of a BPMN diagram was chosen for BPMN DI. As such, BPMN DI does not aim to preserve or interchange any "tool smarts" between the source and target tools (e.g. layout smarts, efficient styling, etc.).

BPMN DI does not address or define the interchange of color information. The use of alternative colors in BPMN is non normative. The meaning or semantic of colors might vary from tool to tool or, from user to user, potentially leading to miss-interpretations.

BPMN DI does not ascertain that the BPMN diagram is syntactically or semantically correct.

12.1.2 Diagram Definition and Interchange

The BPMN DI meta-model, similar to the BPMN abstract syntax meta-model, is defined as a MOF-based meta-model. As such, its instances can be serialized and interchanged using XMI. BPMN DI is also defined by an XML schema. Thus its instances can also be serialized and interchanged using XML.

Both, BPMN DI meta-model and schema are harmonized with a draft version of the OMG Diagram Definition (DD) standard. Annex B contains the relevant parts of the referenced DD specifications that were used as foundation for the BPMN DI model and schema. The provided DD contains two main parts: the Diagram Commons (DC) and the Diagram Interchange (DI). The DC defines common types like bounds and fonts, while the DI provides a framework for defining domain specific diagram models. As a domain specific DI, BPMN DI defines a few new meta-model classes that derive from the abstract classes from DI.

The focus of BPMN DI is the interchange of laid out shapes and edges that constitute a BPMN diagram. Each shape and edge references a particular BPMN model element. The referenced BPMN model elements are all part of the actual BPMN model. As such, BPMN DI is meant to only contain information that is neither present, nor derivable, from the BPMN model when ever possible. Simply put, to render a BPMN diagram both the BPMN DI instance(s) and the referenced BPMN model are REQUIRED.

From the BPMN DI perspective, a BPMN diagram is a particular snap shot of a BPMN model at a certain point in time. Multiple BPMN diagrams can be exchanged referencing model elements from the same BPMN model. Each diagram may provide an incomplete or partial depiction of the content of the BPMN model. BPMN DI does not ascertain that the BPMN diagram is syntactically or semantically correct.

As described in Section •, a BPMN model package consists of one or more files. Each file may contain any number of BPMN diagrams. The exporting tool is free to decide how many diagrams are exported and the importing tool is free to decide if and how to present the contained diagrams to the user.
12.1.3 How to Read this Chapter

The normative BPMN 2.0 Diagram Interchange (BPMN DI) specification has three parts. Section 12.2 defines BPMN DI; an instance of the DI meta-model provided at Annex B. Section 12.3 provides a library of the BPMN element depictions and an unambiguous resolution between a referenced BPMN model element and its depiction. Finally, Section 12.4 provides examples to support the interpretation of the specification. Some BPMN diagram depictions along with their XML BPMN DI serializations are provided.

12.2 BPMN Diagram Interchange (DI) Meta-model

12.2.1 Overview

The BPMN DI is an instance of the DI meta-model provided at Annex B. The basic concept of BPMN DI, as with DI in general, is that serializing a diagram [BPMNDiagram] for interchange requires the specification of a collection of shapes [BPMNShape] and edges [BPMNEdge] on a plane [BPMNPlane].

BPMNPlane, BPMNShape and BPMNEdge MUST reference exactly one abstract syntax BPMN element from the BPMN model using the bpmnElement attribute. The only exception is for a Data Association connected to a Sequence Flow (See Figure 10.68). This is a visual short cut that actually normalizes two Data Associations within the BPMN model. In this case, the resolution is made from the BPMN DI attributes rather than the abstract syntax reference [bpmnElement] (See Table 12.36 - Depiction Resolution for Connecting Objects).

The BPMN DI classes only define the visual properties used for depiction. All other properties that are REQUIRED for the unambiguous depiction of the BPMN element are derived from the referenced bpmnElement.

Multiple depictions of a specific BPMN element in a single diagram is NOT allowed, except for Participants in a choreography (i.e. Participant Bands). For example, it is not allowed to depict a Task twice in the same diagram, but it is allowed to depict the same Task in two different diagrams.

BPMN diagrams may be an incomplete or partial depiction of the content of the BPMN model. Some BPMN elements from a BPMN model may not be present in any of the diagram instances being interchanged.

BPMN DI does not provide for any containment concept. The BPMNPlane is an ordered collection of mixed BPMNShape(s) and BPMNEdge(s). The order of the BPMNShape(s) and BPMNEdge(s) inside a BPMNPlane determines their Z-order (i.e. what is in front of what). BPMNShape(s) and BPMNEdge(s) that are meant to be depicted "on top" of other BPMNShape(s) and BPMNEdge(s) MUST appear after them in the BPMNPlane. Therefore, the exporting tool MUST order all BPMNShape(s) and BPMNEdge(s) such that the desired depiction can be rendered.

12.2.2 Abstract Syntax

This section introduces the Abstract Syntax of BPMN DI. BPMN DI is an instance of the DI meta-model provided at Annex B.
Figure 12.1 - BPMN Diagram

Figure 12.2 - BPMN Plane
Figure 12.3 - BPMN Shape

Figure 12.4 - BPMN Edge
12.2.3 Classifier Descriptions

BPMNDiagram [Class]

BPMNDiagram is a kind of diagram that depicts all or part of a BPMN model.

Description

BPMNDiagram represents a depiction of all or part of a BPMN model. It specializes DI::Diagram and redefines the root element (the top most diagram element) to be of type BPMNPlane. A BPMN diagram can also own a collection of BPMNStyle elements that are referenced by BPMNLabel elements in the diagram. These style elements represent the unique appearance styles used in the diagram.

Abstract Syntax

- Figure 12.1 - BPMN Diagram

Generalizations

- DI::Diagram

Associations

- + plane : BPMNPlane [1] {redefines rootElement}
  a BPMN plane element that is the container of all diagram elements in this diagram.
- + labelStyle : BPMNLabelStyle [*] {subsets style}
  a collection of BPMN label styles that are owned by the diagram and referenced by label elements.

Table 12.1 – BPMNDiagram XML schema

```xml
<xsd:complexType name="BPMNDiagram">
  <xsd:complexContent>
    <xsd:extension base="di:Diagram">
      <xsd:sequence>
        <xsd:element ref="bpmndi:BPMNPlane"/>
        <xsd:element ref="bpmndi:BPMNLabelStyle" minOccurs="0" maxOccurs="unbounded"/>
      </xsd:sequence>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```
**BPMNPlane [Class]**

A BPMNPlane is the BPMNDiagram container of BPMNShape and BPMNEdge.

**Description**

A BPMNPlane specializes DI::Plane and redefines its model element reference to be of type (BPMN) BaseElement. A BPMNPlane can only reference a BaseElement of the types: Process, SubProcess, AdHocSubProcess, Transaction, Collaboration, Choreography or SubChoreography.

BPMNPlane element is always owned by a BPMNDiagram and represents the root diagram element of that diagram. The plane represents a 2 dimensional surface with an origin at (0, 0) along the x and y axes with increasing coordinates to the right and bottom. Only positive coordinates are allowed for diagram elements that are nested in a BPMNPlane. This means that the union of all the nested elements' bounds is deemed to be located at the plane's origin point.

**Abstract Syntax**

- Figure 12.1 - BPMN Diagram
- Figure 12.2 - BPMN Plane

**Generalizations**

- DI::Plane

**Associations**

- + bpmnElement : BaseElement [0..1] {redefines modelElement}
  
  a reference to either a Process, SubProcess, AdHocSubProcess, Transaction, Collaboration, Choreography or SubChoreography in a BPMN model.

**Table 12.2 – BPMNPlane XML schema**

```xml
<xsd:complexType name="BPMNPlane">
  <xsd:complexContent>
    <xsd:extension base="di:Plane">
      <xsd:attribute name="bpmnElement" type="xsd:QName"/>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```

**BPMNShape [Class]**

BPMNShape is a kind of shape that can depict a BPMN model element.

**Description**

BPMNShape represents a depiction of a (typically a node) BPMN model element. It specializes DI::LabeledShape and redefines its model element reference to be of type (BPMN) BaseElement, allowing it to reference an element from a BPMN model.
BPMNShape also contains an optional label of type BPMNLabel that can be nested in the shape when it has a visible textual label with its own bounding box.

The shape also contains a number of normative notational options that can be specified for different types of BPMN elements depicted by the shape. Those options, each represented by a separate property, and described below, allow for recording the specific notational style desired for the shape.

All BPMNShape elements are owned directly by a BPMNPlane (that is the root element in a BPMNDiagram), i.e. shapes are not nested within each other in the BPMN DI model although they may appear that way when depicted. The bounds of a BPMNShape are always relative to that plane's origin point and are REQUIRED to be positive coordinates. Note that the bounds' x and y coordinates are the position of the upper left corner of the shape (relative to the upper left corner of the plane).

Abstract Syntax

- Figure 12.3 - BPMN Shape
- Figure 12.4 - BPMN Edge

Generalizations

- DI::LabeledShape

Attributes

- + isHorizontal : Boolean [0..1]
  
an optional attribute that should be used only for Pools and Lanes. It determines if it should be depicted horizontally (true) or vertically (false).

- + isExpanded : Boolean [0..1]
  
an optional attribute that should be used only for SubProcess, AdHocSubProcess, Transaction, SubChoreographies, CallActivities and CallChoreographies. It determines if it should be depicted expanded (true) or collapsed (false).

- + isMarkerVisible : Boolean [0..1]
  
an optional attribute that should be used only for Exclusive Gateway. It determines if the marker should be depicted on the shape (true) or not (false).

- + participantBandKind : ParticipantBandKind [0..1]
  
an optional attribute that should only be used for Participant Bands. If this attribute is present, it means that the participant should be depicted as a Participant Band instead of as a Pool.

- + isMessageVisible : Boolean [0..1]
  
an optional attribute that should only be used for Participant Bands. It determines if an envelope decorator should be depicted linked to the Participant Band.

- + choreographyActivityShape : BPMNShape [0..1]
  
an optional attribute that should only be used for Participant Bands. It is REQUIRED for a BPMNShape depicting a Participant Band. This is REQUIRED in order to relate the Participant Band to the BPMNShape depicting the Choreography Activity that this Participant Band is related to.
Associations

• + bpmnElement : BaseElement [0..1] {redefines modelElement}
  a reference to a BPMN node element that this shape depicts. Note that although optional a bpmnElement must be provided for a BPMNShape.

• + label : BPMNLabel [0..1] {subsets ownedLabel}
  an optional label that is nested when the shape has a visible text label with its own bounding box.

Table 12.3 – BPMNShape XML schema

```xml
<xsd:complexType name="BPMNShape">
  <xsd:complexContent>
    <xsd:extension base="di:LabeledShape">
      <xsd:sequence>
        <xsd:element ref="bpmndi:BPMNLabel" minOccurs="0"/>
      </xsd:sequence>
      <xsd:attribute name="bpmnElement" type="xsd:QName"/>
      <xsd:attribute name="isHorizontal" type="xsd:boolean"/>
      <xsd:attribute name="isExpanded" type="xsd:boolean"/>
      <xsd:attribute name="isMarkerVisible" type="xsd:boolean"/>
      <xsd:attribute name="isMessageVisible" type="xsd:boolean"/>
      <xsd:attribute name="participantBandKind" type="bpmndi:ParticipantBandKind"/>
      <xsd:attribute name="choreographyActivityShape" type="xsd:QName"/>
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```

ParticipantBandKind [Enumeration]

ParticipantBandKind defines the type of Participant Band to depict.

Description

Participant bands can be depicted in 3 ways:

- a top band is rectangular with rounded corners at the top
- a middle band is rectangular
- a bottom band is rectangular with rounded corners at the bottom

Participant bands can be depicted in 2 shadings:

- initiating (the band should not be shaded)
- non initiating (the band should be shaded)

Abstract Syntax

• Figure 12.3 - BPMN Shape
Literals

- top_initiating
  the band should be depicted as a non shaded top band
- middle_initiating
  the band should be depicted as a non shaded middle band
- bottom_initiating
  the band should be depicted as a non shaded bottom band
- top_non_initiating
  the band should be depicted as a shaded top band
- middle_non_initiating
  the band should be depicted as a shaded middle band
- bottom_non_initiating
  the band should be depicted as a shaded bottom band

BPMNEdge [Class]

BPMNEdge is a kind of edge that can depict a relationship between two BPMN model elements.

Description

BPMNEdge represents a depiction of a relationship between two (source and target) BPMN model elements. It specializes DI::LabeledEdge and redefines its model element reference to be of type (BPMN) BaseElement, allowing it to reference a relationship element from a BPMN model.

BPMNEdge also redefines its source and target references to be of type DiagramElement (either BPMNShape or BPMNEdge).

The source or target definition should only be present if the edge is depicted between a different source or target than the one referenced by the BPMN model element of the BPMNEdge. Only the different source or target is REQUIRED. Both attributes should be present only if both are different. This is the case, for instance, if a Message Flow target is not depicted in the current diagram because it is inside a black box Pool. The Message Flow could then define its target as being the BPMNShape depicting the Pool to connect it to the boundary of that black box Pool.

BPMNEdge also contains an optional label of type BPMNLabel that can be nested in the edge when it has a visible textual label with its own bounding box.

All BPMNEdge elements are owned directly by a BPMNPlane (that is the root element in a BPMNDiagram). The waypoints of BPMNEdge are always relative to that plane's origin point and are REQUIRED to be positive coordinates.

Abstract Syntax

- Figure 12.4 - BPMN Edge
Generalizations

- DI::LabeledEdge

Associations

- + label : BPMNLabel [0..1] {subsets ownedLabel}
  an optional label that is nested when the edge has a visible text label with its own bounding box.

- + bpmnElement : BaseElement [0..1] {redefines modelElement}
  a reference to a connecting BPMN element that this edge depicts. Note that this reference is only optional for the specific case of a Data Association connected to a Sequence Flow; in all other cases a referenced element must be provided.

- + sourceElement : DiagramElement [0..1] {redefines source}
  an optional reference to the edge's source element if it is different from the source inferred from the bpmnElement association.

- + targetElement : DiagramElement [0..1] {redefines target}
  an optional reference to the edge's target element if it is different from the target inferred from the bpmnElement association.

- messageVisibleKind : MessageVisibleKind [0..1]
  an optional attribute that should be used only for Message Flow. It determines if an envelope decorator should be depicted and the kind of envelope to be depicted.

Table 12.4 – BPMNEdge XML schema

```xml
<xsd:complexType name="BPMNEdge">
  <xsd:complexContent>
    <xsd:extension base="di:LabeledEdge">
      <xsd:sequence>
        <xsd:element ref="bpmndi:BPMNLabel" minOccurs="0" />  
      </xsd:sequence>
      <xsd:attribute name="bpmnElement" type="xsd:QName" />  
      <xsd:attribute name="sourceElement" type="xsd:QName" />  
      <xsd:attribute name="targetElement" type="xsd:QName" />  
      <xsd:attribute name="messageVisibleKind" type="bpmndi:MessageVisibleKind" />  
    </xsd:extension>
  </xsd:complexContent>
</xsd:complexType>
```

MessageVisibleKind [Enumeration]

MessageVisibleKind defines the type of envelope that is visible.

Description

MessageVisibleKind is applicable only to Participant Band and Message Flow.
For Message Flow, the envelope should be positioned in the middle of the edge.

For Participant Band, the envelope should be positioned over (for top band) or under (for bottom band) and connected to the band using an association. Note that only Choreography Task Participant Bands are allowed to show the envelope. Middle bands being only used for a SubChoreography can thus not have envelope showing.

Abstract Syntax
- Figure 12.3 - BPMN Shape

Literals
- initiating
  The envelope should be not be shaded
- non_initiating
  The envelope should be shaded

BPMNLabel [Class]
BPMNLabel is a kind of label that depicts textual info about a BPMN element.

Description
BPMNLabel represents a depiction of some textual information about a BPMN element. It specializes DI::Label and redefines its style reference to be of type BPMNLabelStyle, which contains information about the appearance of the label (e.g. the chosen font). The referenced style is owned by the diagram that nests the label.

A BPMN label is not a top-level element but is always nested inside either a BPMNShape or a BPMNEdge. It does not have its own reference to a BPMN element but rather inherits that reference (if any) from its parent shape or edge. The textual info depicted by the label is derived from that referenced BPMN element.

The bounds of BPMNLabel are always relative to the containing plane's origin point. Note that the bounds' x and y coordinates are the position of the upper left corner of the label (relative to the upper left corner of the plane).

Abstract Syntax
- Figure 12.3 - BPMN Shape
- Figure 12.4 - BPMN Edge
- Figure 12.5 - BPMN Label

Generalizations
- DI::Label

Associations
- + labelStyle : BPMNLabelStyle [0..1] {redefines style}
  an optional reference to a label style (owned by the diagram) that gives the appearance options for the label. If not specified, the style of the label can be assumed by a tool.
Table 12.5 – BPMNLabel XML schema

```xml
<xsd:complexType name="BPMNLabel">
    <xsd:complexContent>
        <xsd:extension base="di:Label">
            <xsd:attribute name="labelStyle" type="xsd:QName" />
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```

**BPMNLabelStyle [Class]**

BPMNLabelStyle is a kind of style that gives the appearance options for a BPMNLabel.

**Description**

BPMNLabelStyle represents the appearance options for elements of type BPMNLabel. It specializes DI::Style and contains a description of a font that is used in depicting a BPMNLabel. One or more labels may reference the same BPMNLabelStyle element, which must be owned by a BPMNDiagram.

**Abstract Syntax**

- Figure 12.1 - BPMN Diagram
- Figure 12.5 - BPMN Label

**Generalizations**

- DI::Style

**Attributes**

- + font : Font[1]

  a font object that describes the properties of the font used for depicting the labels that reference this style.

Table 12.6 – BPMNLabelStyle XML schema

```xml
<xsd:complexType name="BPMNLabelStyle">
    <xsd:complexContent>
        <xsd:extension base="di:Style">
            <xsd:sequence>
                <xsd:element ref="dc:Font"/>
            </xsd:sequence>
        </xsd:extension>
    </xsd:complexContent>
</xsd:complexType>
```

    </xsd:restriction>
</xsd:simpleType>
```
12.3 Notational Depiction Library and Abstract Element Resolutions

As a notation, BPMN specifies the depiction for each of the BPMN elements. Serializing a BPMN diagram for interchange requires the specification of a collection of BPMNShape(s) (see page 382) and BPMNEdge(s) (see page 385) on the BPMNPlane (see page 382) of the BPMNDiagram (see page 381). The BPMNShape(s) and BPMNEdge(s) attributes must be populated in such a way as to allow the unambiguous rendering of the BPMN diagram by the receiving party. More specifically, the BPMNShape(s) and BPMNEdge(s) must reference BPMN model element [bpmnElement]. If no bpmnElement is referenced or if the reference is invalid, it is expected that this shape or edge should not be depicted. The only exception is for a Data Association connected to a Sequence Flow (See Figure 10.68). This is a visual short cut that actually normalizes two Data Associations within the BPMN model. In this case, the resolution is made from the BPMN DI attributes rather than the abstract syntax reference [bpmnElement] (See Table 12.36 - Depiction Resolution for Connecting Objects).

When rendering a BPMN diagram, the correct depiction of a BPMNShape or BPMNEdge depends mainly on the referenced BPMN model element [bpmnElement] and its particular attributes and/or references.

The purpose of this section is to: provide a library of the BPMN element depictions, and to provide an unambiguous resolution between the referenced BPMN model element [bpmnElement], BPMNShape or BPMNEdge and their depiction. Depiction resolution tables are provided below for both BPMNShape (Section 12.3.2) and BPMNEdge (Section 12.3.3).

12.3.1 Labels

Both BPMNShape and BPMNEdge may have labels (e.g., its name) placed inside the shape/edge, or above or below the shape/edge, in any direction or location, depending on the preference of the modeler or modeling tool vendor.

Labels are optional for BPMNShape and BPMNEdge. When there is a label, the position of the label is specified by the bounds of the BPMNLabel of the BPMNShape or BPMNEdge. Simply put, label visibility is defined by the presence of the BPMNLabel element. The bounds of the BPMNLabel are optional and always relative to the containing BPMNPlane's origin point (see page 387). The depiction resolution tables provided below exemplify default label positions for BPMNShape kinds (Section 12.3.2) and BPMNEdge kinds (Section 12.3.3) if no BPMNLabel bounds are provided.

Table 12.7 – Complete BPMN DI XML schema

<xsd:simpleType name="MessageVisibleKind">
  <xsd:restriction base="xsd:string">
    <xsd:enumeration value="initiating" />
    <xsd:enumeration value="non_initiating" />
  </xsd:restriction>
</xsd:simpleType>
The text of the label to be rendered is obtained by resolving the name attribute of the referenced BPMN model element [bpmnElement] from the BPMNShape or BPMNEdge. In the particular case when the referenced BPMN model element [bpmnElement] is a DataObjectReference, the text of the label to be rendered is obtained by concatenating the name attribute of the referenced BPMN model element [bpmnElement] and the name attribute of the dataState attribute of this DataObjectReference (see Figure 12.6 - Depicting a Label for a DataObjectReference with its state).

Figure 12.6 - Depicting a Label for a DataObjectReference with its state

The properties of the font to be used for rendering the label are optional and provided by the labelStyle of the BPMNLabel. If not provided, the tool should use its default style to depict the label.

12.3.2 BPMNShape

Markers for Activities

Various BPMN Activities can be decorated with markers at the bottom center of the shape.

Loop Characteristic markers may need to be rendered when the referenced BPMN model element [bpmnElement] of a BPMNShape is a Task, ServiceTask, SendTask, ReceiveTask, UserTask, ManualTask, BusinessRuleTask, ScriptTask, SubProcess, AdHocSubProcess, Transaction or CallActivity. Note that Loop Characteristic Markers (Loop, Multi-Instance - Parallel and Multi-Instance - Sequential) are mutually exclusive markers. That is, only one of them can be present on a single shape. See Table 10.8 - Depiction Resolution for Loop Characteristic Markers. Note that the patterns of Markers depicted in Table 10.8 also apply to Transaction and Call Activity which have different border depictions (i.e. double border or thick border).

A Compensation marker may need to be rendered when the referenced BPMN model element [bpmnElement] of a BPMNShape is a Task, ServiceTask, SendTask, ReceiveTask, UserTask, ManualTask, BusinessRuleTask, ScriptTask, SubProcess, AdHocSubProcess, Transaction or CallActivity. See Table 12.9 - Depiction Resolution for Compensation Marker

In the case of expandable kind of shapes, the markers (Compensation or Loop Characteristic) are placed to the left of the + on the shape.

The Compensation marker may be combined with a Loop Characteristic Marker. All the markers that are present must be grouped and the whole group centered to the bottom of the shape. See Figure 12.7 - Combined Compensation and Loop Characteristic Marker Example.

Note that in the case where the referenced BPMN model element [bpmnElement] of a BPMNShape is an AdHocSubProcess, the shape has its tilde marker to the right of the + (See page 397).

</tbody>
</table>
Tasks [BPMNShape]

There are different types of Tasks identified within BPMN. The specific Task type depiction is obtained by placing a Task type maker in the upper left corner of the Task shape. A Task which is no further specified is called an Abstract Task.

Tasks (Abstract, Service, Send, Receive, User, Manual, Business Rule or Script) can also have Compensation and/or Loop Characteristic markers at the bottom center of the shape as defined above (see page 392).

Call Activities (Calling a Global Task) [BPMNShape]

A Call Activity (Calling a Global Task) must display the Task type marker of the Global Task it calls.

Call Activities (Calling a Global Task) can also have Compensation and/or Loop Characteristic markers at the bottom center of the shape as defined above (see page 392).

Table 12.19 – Depiction Resolution for Call Activities (Calling a Global Task)

**Expanded Call Choreographies (Calling a Choreography) [BPMNShape]**

While the depiction provided in Table 12.33 - Depiction Resolution for Expanded Call Choreographies (Calling a Choreography) contains Participant Bands, Participant Bands are separate shapes that need to be separately defined. Individual Participant Bands are rendered by separate BPMNShape(s), each Participant Band referencing the corresponding participant. See page 419.

An expanded Use Sub Choreography has a loop type that is depicted exactly like the collapsed version in Table 12.32 - Depiction Resolution for Collapsed CallChoreography (Calling a Choreography) above.
Choreography Participant Bands [BPMNShape]

Participant Bands (used in Choreography shapes) are separate shapes that need to be separately defined. Individual Participant Bands are rendered by separate BPMNShape. Each Participant Band referencing the corresponding participant.

Note that for Participant Bands with the envelope decorator, the envelope decorator should be depicted close to the band, vertically centered with the band, and linked to the band using a dotted line. The name of the message may be used as a label for the envelop decorator. BPMN DI does not provide an interchange of the bounds of the label of the envelope decorator.

The bounds of the BPMNShape representing the band do not include the envelope decorator. The envelope decorator is therefore outside of the BPMNShape bounds. BPMN DI does not provide an interchange of the bounds of the envelope decorator.

12.3.3 BPMNEdge

Connecting Objects [BPMNEdge]

The target [targetElement] and source [sourceElement] of a BPMNEdge may be redefined when the depiction of the source or target of the edge is different than the target [targetRef] and source [sourceRef] of the referenced model element [bpmnElement] (e.g. Message flow finishing on the border of a black box Pool or a collapsed Sub-Process rather than the actual Flow Node within the Pool or Sub-Process). In such case, the targetElement and/or sourceElement of the BPMNEdge must point to the appropriate BPMNShape or BPMNEdge.

The source [sourceElement] and target [targetElement] of a BPMNEdge can never be a BPMNShape with participantBandKind set (i.e. only Choreography Activity can be source or target of the BPMNEdge not the Participant Bands).

Note that for Message Flow with an envelope decorator, the envelope decorator should be at the midpoint of the message flow. BPMN DI does not provide an interchange of the bounds of the envelope decorator.

The "diamond" at the source of the Conditional Sequence Flow should not be depicted when the source of a Conditional Sequence Flow is a Gateway. In other words, when the source of a Conditional Sequence Flow is a Gateway, the Conditional Sequence Flow looks like a Sequence Flow.

Even though DataInputAssociation(s) and DataOutputAssociation(s) (Directed Data Associations) always point to DataInput(s) or DataOutput(s) as sources or targets within the BPMN model, they are mostly depicted as starting or finishing on the border of a different depicted element and thus, the target [targetElement] or source [sourceElement] of the BPMNEdge must be specified.

### 12.4 Example(s)

This section provides examples to support interpretation of the BPMN DI specification. Some BPMN diagram depictions along with their XML BPMN DI serializations are provided. The XML samples provided in this section present only BPMN DI instances and omit the BPMN 2.0 abstract syntax.

For readability purposes, the bpmnElement that is referenced by the BPMNPlane, BPMNShape and BPMNEdge use a representative string pattern. This string pattern is:

BPMNModelClassName_BPMNModelNameAttributeValue

For example: "Task_Activity" for a Task named "Activity".
In the provided XML serializations, the di namespace refers to the Diagram Interchange namespace defined in Annex B, and the dc namespace refers to the Diagram Common namespace also defined in Annex B.

12.4.1 Depicting Content in a Sub-Process

This section shows various ways of depicting the content of a Sub-Process of a same BPMN model.

The BPMN model contains a process composed of a none start event (named "StartEvent"), a sub-process (named "SubProcess") and a none end event (named "EndEvent"). There is a sequence flow (named "a") between the start event (named "StartEvent") and the sub-process (named "SubProcess") and a sequence flow (named "d") between the sub-process (named "SubProcess") and the end event (named "EndEvent").

The sub-process (named "SubProcess") is composed of a none start event (named "SubProcessStart"), an abstract task (named "Activity") and a none end event (named "SubProcessEnd"). There is a sequence flow (named "b") between the start event (named "SubProcessStart") and the task (named "Activity") and a sequence flow (named "c") between the task (named "Activity") and the end event (named "SubProcessEnd").

Expanded Sub-Process

First, a BPMN diagram depicts the BPMN model with the expanded sub-process showing its content (see Figure 12.8). This leads to a BPMN DI serialization of a single diagram that depicts this process (see Table 12.37 - Expanded Sub-Process BPMN DI instance).

---

Figure 12.8 - Expanded Sub-Process Example
Table 12.37 – Expanded Sub-Process BPMN DI instance

```xml
<BPMNDiagram name="Events Inside the Sub Process" resolution="72">
  <BPMNPlane bpmnElement="Process_Process">

    </BPMNEdge>
    <BPMNEdge bpmnElement="SequenceFlow_d" sourceElement="BorderEnd">
      <di:waypoint x="540.0" y="240.0"/>
      <di:waypoint x="604.0" y="240.0"/>
      <BPMNLabel/>
    </BPMNEdge>
  </BPMNPlane>
</BPMNDiagram>
```
Expanded Sub-Process with Start and End Events on Border

An alternative to depicting the same BPMN model of Section 12.4.1 would be to place the sub-process start and end events on the border of the sub-process (see Figure 12.9). In the BPMN DI serialization of this diagram (see Table 12.40 - Expanded Sub-Process with Start and End Events on Border BPMN DI instance), the target of the sequence flow named "a" and the source of the sequence flow named "d" are the start and end events on the boundary of the sub-process.

Compare the target of the sequence flow named "a" and the source of the sequence flow named "d" of Table 12.37 - Expanded Sub-Process BPMN DI instance with that of Table 12.38 - Start and End Events on the Border BPMN DI instance.

![Figure 12.9 - Start and End Events on the Border Example](image-url)

**Table 12.37 – Expanded Sub-Process BPMN DI instance**

```
<Table name="StartAndEndEventsOnTheBorder" resolution="72">
  <Panel bpmnElement="Process_Process">
    <Panel bpmnElement="StartEvent_StartEvent">
      <dc:Bounds height="30.0" width="30.0" x="120.0" y="225.0"/>
    </Panel>
  </Panel>

13 BPMN Execution Semantics

Note – The content of this chapter is REQUIRED for BPMN Process Execution Conformance or for BPMN Complete Conformance. However, this chapter is NOT REQUIRED for BPMN Process Modeling Conformance, BPMN Choreography Conformance, or BPMN BPEL Process Execution Conformance. For more information about BPMN conformance types, see page 2.

This section defines the execution semantics for orchestrations in BPMN 2.0. The purpose of this execution semantics is to describe a clear and precise understanding of the operation of the elements. However, for some elements only conceptual model is provided which does not specify details needed to execute them on an engine. These elements are called non-operational. Implementations MAY extend the semantics of non-operational elements to make them executable, but this is considered to be an optional extension to BPMN. Non-operational elements MAY be ignored by implementations conforming to BPMN Process Execution Conformance type. The following elements are non-operational:

- Manual Task
- Abstract Task
- DataState
- IORules
- Ad-Hoc Process
- ItemDefinitions with an itemKind of Physical
- the inputSetWithWhileExecuting attribute of DataInput
- the outputSetWithWhileExecuting attribute of DataOutput
- the isClosed attribute of Process
- the isImmediate attribute of Sequence Flow

The execution semantics are described informally (textually), and this based on prior research involving the formalization of execution semantics using mathematical formalisms.

This section provides the execution semantics of elements through the following structure:

- A description of the operational semantics of the element,
- Exception issues for the element where relevant,
- List of workflow patterns\(^1\) supported by the element where relevant.

\(^1\) http://www.workflowpatterns.com/patterns/control/index.php
13.1 Process Instantiation and Termination

A **Process** is instantiated when one of its **Start Events** occurs. Each occurrence of a **Start Event** creates a new **Process Instance** unless the **Start Event** participates in a **Conversation** that includes other **Start Events**. In that case, a new **Process instance** is only created if none already exists for the specific **Conversation** (identified through its associated correlation information) of the **Event** occurrence. Subsequent **Start Events** that share the same correlation information as a **Start Event** that created a **Process instance** are routed to that **Process instance**. Note that a **global Process** MUST neither have any empty **Start Event** nor any **Gateway** or **Activity** without **incoming Sequence Flows**. An exception is the **Event Gateway**.

A **Process** can also be started via an **Event-Based Gateway** or a **Receive Task** that has no **incoming Sequence Flows** and its **instantiate flag** set to **true**. If the **Event-Based Gateway** is **exclusive**, the first matching **Event** will create a new **instance** of the **Process**. The **Process** then does not wait for the other **Events** originating from the same **Event-Based Gateway** (see also semantics of the **Event-Based Exclusive Gateway** on page 452). If the **Event-Based Gateway** is **parallel**, also the first matching **Event** creates a new **Process instance**. However, the **Process** then waits for the other **Events** to arrive. As stated above, those **Events** MUST have the same correlation information as the **Event** that arrived first. A **Process instance** completes only if all **Events** that succeed a **Parallel Event-Based Gateway** have occurred.

To specify that the instantiation of a **Process** waits for multiple **Start Events** to happen, a **Multiple Parallel Start Event** can be used.

Note that two **Start Events** are alternative, A **Process instance** triggered by one (1) of the **Start Events** does not wait for an alternative **Start Event** to occur. Note that there MAY be multiple instantiating **Parallel Event-Based Gateways**. This allows the modeler to express that either all the **Events** after the first **Gateway** occur or all the **Events** after the second **Gateway** and so forth.

Each **Start Event** that occurs creates a **token** on its **outgoing Sequence Flows**, which is followed as described by the semantics of the other **Process** elements.

- A **Process instance** is completed, if and only if the following three conditions hold:
  - If the **instance** was created through an instantiating **Parallel Gateway**, then all subsequent **Events** (of that **Gateway**) MUST have occurred.
  - There is no **token** remaining within the **Process instance**.
  - No **Activity** of the **Process** is still active.

For a **Process instance** to become completed, all **tokens** in that **instance** MUST reach an end node, i.e., a node without **outgoing Sequence Flows**. A **token** reaching an **End Event** triggers the behavior associated with the **Event** type is, e.g., the associated **Message** is sent for a **Message End Event**, the associated **Signal** is sent for a **Signal End Event**, and so on. If a **token** reaches a **Terminate End Event**, the entire **Process** is abnormally terminated.

13.2 Activities

This section specifies the semantics of **Activities**. First the semantics that is common to all **Activities** is described. Subsequently the semantics of special types of **Activities** is described.
13.2.1 Sequence Flow Considerations

The nature and behavior of Sequence Flows is described in 8.3.13, 'Sequence Flow'. But there are special considerations relative to Sequence Flows when applied to Activities. An Activity that is the target of multiple Sequence Flows participates in “uncontrolled flow.”

To facilitate the definition of Sequence Flow (and other Process elements) behavior, we employ the concept of a token that will traverse the Sequence Flows and pass through the elements in the Process. A token is a theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it “traverses” the structure of the Process. However, modeling and execution tools that implement BPMN are NOT REQUIRED to implement any form of token.

Uncontrolled flow means that, for each token arriving on any incoming Sequence Flows into the Activity, the Task will be enabled independently of the arrival of tokens on other incoming Sequence Flows. The presence of multiple incoming Sequence Flows behaves as an exclusive gateway. If the flow of tokens into the Task needs to be ‘controlled,’ then Gateways (other than Exclusive) should be explicitly included in the Process flow prior to the Task to fully eliminate semantic ambiguities.

If an Activity has no incoming Sequence Flows, the Activity will be instantiated when the containing Process or Sub-Process is instantiated. Exceptions to this are Compensation Activities, as they have specialized instantiation behavior.

Activities can also be source of Sequence Flows. If an Activity has multiple outgoing Sequence Flows, all of them will receive a token when the Activity transitions to the Completed state. Semantics for token propagation for other termination states is defined below. Thus, multiple outgoing Sequence Flows behaves as a parallel split. Multiple outgoing Sequence Flows with conditions behaves as an inclusive split. A mix of multiple outgoing Sequence Flows with and without conditions is considered as a combination of a parallel and an inclusive split as shown in the Figure 13.1.

![Figure 13.1 - Behavior of multiple outgoing Sequence Flows of an Activity](image)

If the Activity has no outgoing Sequence Flows, the Activity will terminate without producing any tokens and termination semantics for the container is then applied.

Token movement across a Sequence Flow does not have any timing constraints. A token might take a long or short time to move across the Sequence Flow. If the isImmediate attribute of a Sequence Flow has a value of false, or has no value and is taken to mean false, then Activities not in the model MAY be executed while the token is moving along the Sequence Flow. If the isImmediate attribute of a Sequence Flow has a value of true, or has no value and is taken to mean true, then Activities not in the model MAY NOT be executed while the token is moving along the Sequence Flow.
13.2.2 Activity

An Activity is a Process step that can be atomic (Tasks) or decomposable (Sub-Processes) and is executed by either a system (automated) or humans (manual). All Activities share common attributes and behavior such as states and state transitions. An Activity, regardless of type, has lifecycle generally characterizing its operational semantics. The lifecycle, described as a UML state diagram in Figure 13.2, entails states and transitions between the states.

![Figure 13.2 - The Lifecycle of a BPMN Activity](image)

Figure 13.2 - The Lifecycle of a BPMN Activity
The lifecycle of an Activity is described as follows:

- An Activity is Ready for execution if the REQUIRED number of tokens is available to activate the Activity. The REQUIRED number of tokens (one or more) is indicated by the attribute StartQuantity. If the Activity has more than one Incoming Sequence Flows, there is an implied Exclusive Gateway that defines the behavior.

- When some data InputSet becomes available, the Activity changes from Ready to the Active state. The availability of a data InputSet is evaluated as follows. The data InputSets are evaluated in order. For each InputSet, the data inputs are filled with data coming from the elements of the context such as Data Objects or Properties by triggering the input Data Associations. An InputSet is available if each of its REQUIRED Data Inputs is available. A data input is REQUIRED by a data InputSet if it is not optional in that InputSet. If an InputSet is available, it is used to start the Activity. Further InputSets are not evaluated. If an InputSet is not available, the next InputSet is evaluated. The Activity waits until one InputSet becomes available. Please refer to Section 10.3.2 (page 232) for a description of the execution semantics for Data Associations.

- An Activity, if Ready or Active, can be Withdrawn from being able to complete in the context of a race condition. This situation occurs for Tasks that are attached after an Event-Based Exclusive Gateway. The first element (Task or Event) that completes causes all other Tasks to be withdrawn.

- If an Activity fails during execution, it changes from the state Active to Failed.
  - If a fault happens in the environment of the Activity, termination of the Activity is triggered, causing the Activity to go into the state Terminated.
  - If an Activity’s execution ends without anomalies, the Activity’s state changes to Completing. This intermediate state caters for processing steps prior to completion of the Activity. An example of where this is useful is when non-interrupting Event Handlers (proposed for BPMN 2.0) are attached to an Activity. They need to complete before the Activity to which it is attached can complete. The state Completing of the main Activity indicates that the execution of the main Activity has been completed, however, the main Activity is not allowed to be in the state Completed, as it still has to wait for all non-interrupting Event Handlers to complete. The state Completing does not allow further processing steps, otherwise allowed during the execution of the Activity. For example, new attached non-interrupting Event Handlers MAY be created as long as the main Activity is in state Active. However, once in the state Completing, running handlers should be completed with no possibility to create new ones.

- An Activity’s execution is interrupted if an interrupting Event is raised (such as an error) or if an interrupting Event Sub-Process is initiated. In this case, the Activity’s state changes to Failing (in case of an error) or Terminating (in case any other interrupting Event). All nested Activities that are not in Ready, Active or a final state (Completed, Compensated, Failed, etc.) and non-interrupting Event Sub-Processes are terminated. The data context of the Activity is preserved in case an interrupting Event Sub-Process is invoked. The data context is released after the Event Sub-Process reaches a final state.

- After all completion dependencies have been fulfilled, the state of the Activity changes to Completed. The outgoing Sequence Flows becomes active and a number of tokens, indicated by the attribute CompletionQuantity, is placed on it. If there is more than one (1) outbound Sequence Flows for an Activity, it behaves like an implicit Parallel Gateway. Upon completion, also a data OutputSet of the Activity is selected as follows. All OutputSets are checked for availability in order. An OutputSet is available if all its REQUIRED Data Outputs are available. A data output is REQUIRED by an OutputSet if it is not optional in that OutputSet. If the data OutputSet is available, data is pushed into the context of the Activity by triggering the output Data Associations of all its data outputs. Further OutputSets are not evaluated. If the data OutputSet is not available, the next data OutputSet is checked. If no OutputSet is available, a runtime exception is thrown. If the Activity has an associated IORule, the chosen OutputSet is checked against that IORule, i.e., it is checked whether the InputSet that was used in starting the Activity instance is together with the chosen OutputSet compliant with the IORule. If not, a runtime exception is thrown.

- Only completed Activities could, in principle, be compensated, however, the Activity can end in state Completed,
as compensation might not be triggered or there might be no compensation handler specified. If the compensation handler is invoked, the Activity changes to state Compensating until either compensation finishes successfully (state Compensated), an exceptions occurs (state Failed) or controlled or uncontrolled termination is triggered (state Terminated).

13.2.3 Task

Task execution and completion for the different Task types are as follows:

- **Service Task**: Upon activation, the data in the inMessage of the Operation is assigned from the data in the Data Input of the Service Task the Operation is invoked. On completion of the service, the data in the Data Output of the Service Task is assigned from the data in the outMessage of the Operation, and the Service Task completes. If the invoked service returns a fault, that fault is treated as interrupting error, and the Activity fails.

- **Send Task**: Upon activation, the data in the associated Message is assigned from the data in the Data Input of the Send Task. The Message is sent and the Send Task completes.

- **Receive Task**: Upon activation, the Receive Task begins waiting for the associated Message. When the Message arrives, the data in the Data Output of the Receive Task is assigned from the data in the Message, and Receive Task completes. For key-based correlation, only a single receive for a given CorrelationKey can be active, and thus the Message matches at most one Process instance. For predicate-based correlation, the Message can be passed to multiple Receive Tasks. If the Receive Task’s instantiate attribute is set to true, the Receive Task itself can start a new Process instance.

- **User Task**: Upon activation, the User Task is distributed to the assigned person or group of people. When the work has been done, the User Task completes.

- **Manual Task**: Upon activation, the manual task is distributed to the assigned person or group of people. When the work has been done, the Manual Task completes. This is a conceptual model only; a Manual Task is never actually executed by an IT system.

- **Business Rule Task**: Upon activation, the associated business rule is called. On completion of the business rule, the Business Rule Task completes.

- **Script Task**: Upon activation, the associated script is invoked. On completion of the script, the Script Task completes.

- **Abstract Task**: Upon activation, the Abstract Task completes. This is a conceptual model only; an Abstract Task is never actually executed by an IT system.

13.2.4 Sub-Process/Call Activity

A Sub-Process is an Activity which encapsulates a Process which is in turn modeled by Activities, Gateways, Events, and Sequence Flows. Once a Sub-Process is instantiated, its elements behave as in a normal Process. The instantiation and completion of a Sub-Process is defined as follows.

- A Sub-Process is instantiated when it is reached by a Sequence Flow token. The Sub-Process has either a unique empty Start Event, which gets a token upon instantiation, or it has no Start Event but Activities and Gateways without incoming Sequence Flows. In the latter case all such Activities and Gateways get a token. A Sub-Process MUST not have any non-empty Start Events.

- If the Sub-Process does not have incoming Sequence Flows but Start Events that are target of Sequence Flows from outside the Sub-Process, the Sub-Process is instantiated when one of these Start Events is reached by a token. Multiple such Start Events are alternative, i.e., each such Start Event that is reached by a
A Sub-Process instance completes when there are no more tokens in the Sub-Process and none of its Activities is still active.

If a “terminate” End Event is reached, the Sub-Process is abnormally terminated. For a “cancel” End Event, the Sub-Process is abnormally terminated and the associated Transaction is aborted. Control leaves the Sub-Process through a cancel intermediate boundary Event. For all other End Events, the behavior associated with the Event type is performed, e.g., the associated Message is sent for a Message End Event, the associated signal is sent for a signal End Event, and so on.

If a global Process is called through a Call Activity, then the Call Activity has the same instantiation and termination semantics as a Sub-Process. However, in contrast to a Sub-Process, the global Process that is called MAY also have non-empty Start Events. These non-empty Start Events are alternative to the empty Start Event and hence they are ignored when the Process is called from another Process.

13.2.5 Ad-Hoc Sub-Process

An Ad-Hoc Sub-Process or Process contains a number of embedded inner Activities and is intended to be executed with a more flexible ordering compared to the typical routing of Processes. Unlike regular Processes, it does not contain a complete, structured BPMN diagram description—i.e., from Start Event to End Event. Instead the Ad-Hoc Sub-Process contains only Activities, Sequence Flows, Gateways, and Intermediate Events. An Ad-Hoc Sub-Process MAY also contain Data Objects and Data Associations. The Activities within the Ad-Hoc Sub-Process are not REQUIRED to have incoming and outgoing Sequence Flows. However, it is possible to specify Sequence Flows between some of the contained Activities. When used, Sequence Flows will provide the same ordering constraints as in a regular Process. To have any meaning, Intermediate Events will have an outgoing Sequence Flows and they can be triggered multiple times while the Ad-Hoc Sub-Process is active.

The contained Activities are executed sequentially or in parallel, they can be executed multiple times in an order that is only constrained through the specified Sequence Flows, Gateways, and data connections.

Operational semantics

At any point in time, a subset of the embedded Activities is enabled. Initially, all Activities without incoming Sequence Flows are enabled. One of the enabled Activities is selected for execution. This is not done by the implementation but usually by a Human Performer. If the ordering attribute is set to sequential, another enabled Activity can be selected for execution only if the previous one has terminated. If the ordering attribute is set to parallel, another enabled Activity can be selected for execution at any time. This implies the possibility of the multiple parallel instances of the same inner Activity.

After each completion of an inner Activity, a condition specified through the completionCondition attribute is evaluated:

If false, the set of enabled inner Activities is updated and new Activities can be selected for execution.

If true, the Ad-Hoc Sub-Process completes without executing further inner Activities. In case the ordering attribute is set to parallel and the attribute cancelRemainingInstances is true, running instances of inner Activities are canceled. If cancelRemainingInstances is set to false, the Ad-Hoc Sub-Process completes after all remaining inner instances have completed or terminated.

When an inner Activity with outgoing Sequence Flows completes, a number of tokens are produced on its outgoing Sequence Flows. This number is specified through its attribute completionQuantity. The resulting state MAY contain also other tokens on incoming Sequence Flows of either Activities, converging Parallel or Complex Gateways, or an Intermediate Event. Then all tokens are propagated as far as possible, i.e., all activated Gateways are executed until no Gateway and Intermediate Event is activated anymore.
Consequently, a state is obtained where each token is on an incoming Sequence Flow of either an inner Activity, a converging Parallel or Complex Gateway or an Intermediate Event. An inner Activity is now enabled if it has either no incoming Sequence Flows or there are sufficiently many tokens on its incoming Sequence Flows (as specified through startQuantity).

Workflow patterns: WCP-17 Interleaved parallel routing.

### 13.2.6 Loop Activity

The Loop Activity is a type of Activity that acts as a wrapper for an inner Activity that can be executed multiple times in sequence.

**Operational semantics:** Attributes can be set to determine the behavior. The Loop Activity executes the inner Activity as long as the loopCondition evaluates to true. A testBefore attribute is set to decide when the loopCondition should be evaluated: either before the Activity is executed or after, corresponding to a pre- and post-tested loop respectively. A loopMaximum attribute can be set to specify a maximal number of iterations. If it is not set, the number is unbounded.

**Workflow Patterns Support:** WCP-21 Structured Loop.

### 13.2.7 Multiple Instances Activity

The multi-instance (MI) Activity is a type of Activity that acts as a wrapper for an Activity which has multiple instances spawned in parallel or sequentially.

**Operational semantics:** The MI specific attributes are used to configure specific behavior. The attribute isSequential determines whether instances are generated sequentially (true) or in parallel (false). The number of instances to be generated is either specified by the integer-valued Expression loopCardinality or as the cardinality of a specific collection-valued data item of the data input of the MI Activity. The latter is described in detail below.

The number of instances to be generated is evaluated once. Subsequently the number of instances are generated. If the instances are generated sequentially, a new instance is generated only after the previous has been completed. Otherwise, multiple instances to be executed in parallel are generated.

Attributes are available to support the different possibilities of behavior. The completionCondition Expression is a boolean predicate that is evaluated every time an instance completes. When evaluated to true, the remaining instances are cancelled, a token is produced for the outgoing Sequence Flows, and the MI Activity completes.

The attribute behavior defines if and when an Event is thrown from an Activity instance that is about to complete. It has values of none, one, all, and complex, assuming the following behavior:

- **none:** an EventDefinition is thrown for all instances completing.
- **one:** an EventDefinition is thrown upon the first instance completing.
- **all:** no Event is ever thrown.
- **complex:** the complexBehaviorDefinitions are consulted to determine if and which Events to throw.

For the behaviors of none and one, an EventDefinition (which is referenced from MultipleInstanceLoopCharacteristics through the noneEvent and oneEvent associations, respectively) is thrown which automatically carries the current runtime attributes of the MI Activity. That is, the ItemDefinition of these SignalEventDefinitions is implicitly given by the specific runtime attributes of the MI Activity.
The `complexBehaviorDefinition` association references multiple `ComplexBehaviorDefinition` entities which each point to a boolean condition being a `FormalExpression` and an `Event` which is an `ImplicitThrowEvent`. Whenever an `Activity instance` completes, the conditions of all `ComplexBehaviorDefinition` entities are evaluated. For each `ComplexBehaviorDefinition` whose condition is evaluated to `true`, the associated `Event` is automatically thrown. That is, a single `Activity` completion can lead to multiple different `Events` that are thrown. The `Events` can then be caught on the boundary of the `MI Activity`. Multiple `ComplexBehaviorDefinition` offer an easy way of implicitly spawning different flow at the `MI Activity` boundary for different situations indicating different states of progress in the course of executing the `MI Activity`.

The `completionCondition`, the condition in the `ComplexBehaviorDefinition`, and the `DataInputAssociation` of the `Event` in the `ComplexBehaviorDefinition` can refer to the `MI Activity instance` attributes and the `loopDataInput`, `loopDataOutput`, `inputDataItem`, and `outputDataItem` that are referenced from the `MultiInstanceLoopCharacteristics`.

In practice, an `MI Activity` is executed over a data `collection`, processing as input the data values in the `collection` and producing as `output` data values in a `collection`. The `input` data collection is passed to the `MI outer Activity's loopDataInput` from a `Data Object` in the `Process scope` of the `MI Activity`. Under `BPMN` data flow constraints, the `Data Object` is linked to `MI activity's loopDataInput` through a `DataInputAssociation`. To indicate that the `Data Object` is a `collection`, its respective symbol is marked with the `MI indicator` (three-bar). The items of the `loopDataInput collection` are used to determine the number of `instances` REQUIRED to be executed (whether sequentially or in parallel). Accordingly, the inner `instances` are created and data values from the `loopDataInput` are extracted and assigned to the respective `instances`. Specifically, the values from the `loopDataInput` items are passed to an `inputDataItem`, created in the scope of the outer `Activity`. The value in the `inputDataItem` can be passed to the `loopDataInput` of each inner `instance`, where a `DataInputAssociation` links both. The process of extraction is left underspecified. In practice, it would entail a special-purpose mediator which not only provides the extraction and data assignment, but also any necessary data transformation.

Each `instance` processes the data value of its `DataInput`. It produces a value in its `DataOutput` if it completes successfully. The `DataOutput` value of the `instance` is passed to a corresponding `outputDataItem` in the outer `Activity`, where a `DataOutputAssociation` links both. Each `outputDataItem` value is updated in the `loopDataOutput collection`, in the corresponding item. The mechanism of this update is left underspecified, and again would be implemented through a special purpose mediator. The `loopDataOutput` is passed to the `MI Activity's Process scope` through a `Data Object` that has a `DataOutputAssociation` linking both.

It should be noted that the `collection` in the `Process scope` should not be accessible until all its items have been written to. This is because, it could be accessed by an `Activity` running concurrently, and therefore control flow through `token passing` cannot guarantee that the `collection` is fully written before it is accessed.

The `MI Activity` is `compensated` only if all its `instances` have completed successfully.

13.3 Gateways

This section describes the behavior of Gateways.

13.3.1 Parallel Gateway (Fork and Join)

![Figure 13.3 - Merging and Branching Sequence Flows for a Parallel Gateway](image)

On the one hand, the Parallel Gateway is used to synchronize multiple concurrent branches (merging behavior). On the other hand, it is used to spawn new concurrent threads on parallel branches (branching behavior).

13.3.2 Exclusive Gateway (Exclusive Decision (data-based) and Exclusive Merge)

The **Exclusive Gateway** has pass-through semantics for a set of incoming branches (merging behavior). Further on, each activation leads to the activation of exactly one out of the set of outgoing branches (branching behavior).

![Diagram of Exclusive Gateway](image)

**Figure 13.4 - Merging and Branching Sequence Flows for an Exclusive Gateway**

</tr>
<tr>
<td></td>
<td>- does not visit the <strong>Inclusive Gateway</strong>.</td>
</tr>
</tbody>
</table>

Upon execution, a *token* is consumed from each incoming **Sequence Flow** that has a *token*. A *token* will be produced on some of the outgoing **Sequence Flows**.

In order to determine the outgoing **Sequence Flows** that receive a *token*, all conditions on the outgoing **Sequence Flows** are evaluated. The evaluation does not have to respect a certain order.

For every condition which evaluates to *true*, a *token* MUST be passed on the respective **Sequence Flow**.

If and only if none of the conditions evaluates to *true*, the *token* is passed on the default **Sequence Flow**.

In case all conditions evaluate to *false* and a default flow has not been specified, the **Inclusive Gateway** throws an exception.

13.3.4 Event-based Gateway (Exclusive Decision (event-based))

![Figure 13.6 - Merging and branching Sequence Flows for an Event-Based Gateway](image)

The **Event-Based Gateway** has pass-through semantics for a set of incoming branches (merging behavior). Exactly one of the outgoing branches is activated afterwards (branching behavior), depending on which of **Events** of the **Gateway** configuration is first triggered. The choice of the branch to be taken is deferred until one of the subsequent **Tasks** or **Events** completes. The first to complete causes all other branches to be withdrawn.

When used at the **Process** start as a **Parallel Event Gateway**, only message-based triggers are allowed. The **Message triggers** that are part of the **Gateway** configuration **MUST** be part of a **Conversation** with the same correlation information. After the first **trigger** instantiates the **Process**, the remaining **Message triggers** will be a part of the **Process instance** that is already active (rather than creating new **Process instances**).

<table>

13.3.5 Complex Gateway (related to Complex Condition and Complex Merge)

![Figure 13.7 - Merging and branching Sequence Flows for a Complex Gateway](image)

The **Complex Gateway** facilitates the specification of complex synchronization behavior, in particular race situations. The diverging behavior is similar to the **Inclusive Gateway**. Each incoming gate of the **Complex Gateway** has an attribute **activationCount**, which can be used in an **Expression** as an integer-valued variable. This variable represents the number of **tokens** that are currently on the respective **incoming Sequence Flows**. The **Complex Gateway** has an attribute **activationExpression**. An **activationExpression** is a boolean **Expression**.
that refers to data and to the activationCount of incoming gates. For example, an activationExpression could be x1+x2+...+xm >= 3 stating that it needs 3 out of the m incoming gates to have a token in order to proceed. To prevent undesirable oscillation of activation of the Complex Gateway, ActivationCount variables should only be used in subexpressions of the form expr >= const where expr is an arithmetic Expression that uses only addition and const is an Expression whose evaluation remains constant during execution of the Process.

Each outgoing Sequence Flow of the Complex Gateway has a boolean condition that is evaluated to determine whether that Sequence Flow receives a token during the execution of the Gateway. Such a condition MAY refer to internal state of the Complex Gateway. There are two states: waiting for start (represented by the runtime attribute waitingForStart = true) and waiting for reset (waitingForStart=false).
### Table 13.5 – Semantics of the Complex Gateway

| Operational Semantics | The **Complex Gateway** is in one of the two states: *waiting for start* or *waiting for reset*, initially it is in *waiting for start*. If it is *waiting for start*, then it waits for the activationExpression to become *true*. The activationExpression is not evaluated before there is at least one token on some incoming **Sequence Flow**. When it becomes *true*, a token is consumed from each incoming **Sequence Flow** that has a token. To determine which outgoing **Sequence Flow** receive a token, all conditions on the outgoing **Sequence Flows** are evaluated (in any order). Those and only those that evaluate to *true* receive a token. If no condition evaluates to *true*, and only then, the default **Sequence Flow** receives a token. If no default flow is specified an exception is thrown. The **Gateway** changes its state to *waiting for reset*. The **Gateway** remembers from which of the incoming **Sequence Flows** it consumed tokens in the first phase.

When *waiting for reset*, the **Gateway** waits for a token on each of those incoming **Sequence Flows** from which it has not yet received a token in the first phase unless such a token is not expected according to the join behavior of an **inclusive Gateway**. More precisely, the **Gateway** being *waiting for reset*, resets when for every directed path formed by sequence flow that

- starts with a **Sequence Flow** \( f \) of the diagram that has a token,

- ends with an incoming **Sequence Flow** of the **Complex Gateway** that has no token and has not consumed a token in the first phase, and that

- does not visit the **Complex Gateway**,

- There is also a directed path formed by **Sequence Flow** that

  - starts with \( f \),

  - ends with an incoming **Sequence Flow** of the **Complex Gateway** that has a token or from which a token was consumed in the first phase, and that,

  - does not visit the **Complex Gateway**

If the **Complex Gateway** is contained in a **Sub-Process**, then no paths are considered that cross the boundary of that **Sub-Process**.

When the **Gateway** resets, it consumes a token from each incoming **Sequence Flow** that has a token and from which it had not yet consumed a token in the first phase. It then evaluates all conditions on the outgoing **Sequence Flows** (in any order) to determine which **Sequence Flows** receives a token. Those and only those that evaluate to *true* receive a token. If no condition evaluates to *true*, and only then, the default **Sequence Flow** receives a token. The **Gateway** changes its state back to the state *waiting for start*. Note that the **Gateway** might not produce any tokens in this phase and no exception is thrown. Note that the conditions on the outgoing **Sequence Flows** MAY evaluate differently in the two phases, e.g., by referring to the state of the **Gateway** (runtime attribute *waitingForStart*).

Note that if the activationCondition never becomes *true* in the first phase, tokens are blocked indefinitely at the **Complex Gateway**, which MAY cause a deadlock of the entire **Process**. |
13.4 Events

This section describes the handling of Events.

13.4.1 Start Events

For single Start Events, handling consists of starting a new Process instance each time the Event occurs. Sequence Flows leaving the Event are then followed as usual.

If the Start Event participates in a Conversation that includes other Start Events, a new Process instance is only created if none already exists for the specific Conversation (identified through its associated correlation information) of the Event occurrence.

A Process can also be started via an Event-Based Gateway. In that case, the first matching Event will create a new instance of the Process, and waiting for the other Events originating from the same decision stops, following the usual semantics of the Event-Based Exclusive Gateway. Note that this is the only scenario where a Gateway can exist without an incoming Sequence Flows.

It is possible to have multiple groups of Event-Based Gateways starting a Process, provided they participate in the same Conversation and hence share the same correlation information. In that case, one Event out of each group needs to arrive; the first one creates a new Process instance, while the subsequent ones are routed to the existing instance, which is identified through its correlation information.

13.4.2 Intermediate Events

For Intermediate Events, the handling consists of waiting for the Event to occur. Waiting starts when the Intermediate Event is reached. Once the Event occurs, it is consumed. Sequence Flows leaving the Event are followed as usual. For catch Message Intermediate Events, the Message correlation behavior is the same as for Receive Tasks -- see Section 13.2.3.

13.4.3 Intermediate Boundary Events

For boundary Events, handling first consists of consuming the Event occurrence. If the cancelActivity attribute is set, the Activity the Event is attached to is then cancelled (in case of a multi-instance, all its instances are cancelled); if the attribute is not set, the Activity continues execution (only possible for Message, Signal, Timer, and Conditional Events, not for Error Events). Execution then follows the Sequence Flow connected to the boundary Event. For boundary Message Intermediate Events, the Message correlation behavior is the same as for Receive Tasks -- see Section 13.2.3.
13.4.4 Event Sub-Processes

Event Sub-Processes allow to handle an Event within the context of a given Sub-Processes or Process. An Event Sub-Process always begins with a Start Event, followed by Sequence Flows. Event Sub-Processes are a special kind of Sub-Process: they create a scope and are instantiated like a Sub-Process, but they are not instantiated by normal control flow but only when the associated Start Event is triggered. Event Sub-Processes are self-contained and MUST not be connected to the rest of the Sequence Flows in the Sub-Processes; also they cannot have attached boundary Events. They run in the context of the Sub-Process, and thus have access to its context.

An Event Sub-Process cancels execution of the enclosing Sub-Process, if the isInterrupting attribute of its Start Event is set; for a multi-instance Activity this cancels only the affected instance. If the isInterrupting attribute is not set (not possible for an Error Event Sub-Processes), execution of the enclosing Sub-Process continues in parallel to the Event Sub-Process.

An Event Sub-Process can optionally retrigger the Event through which it was triggered, to cause its continuation outside the boundary of the associated Sub-Process. In that case the Event Sub-Process is performed when the Event occurs; then control passes to the boundary Event, possibly canceling the Sub-Process (including running handlers).

Operational semantics

- An Event Sub-Process becomes initiated, and thus Enabled and Running, through the Activity to which it is attached. The Event Handler MAY only be initiated after the parent Activity is Running.
- More than one non-interrupting Event Handler MAY be initiated and they MAY be initiated at different times. There might be multiple instances of the non-interrupting Event Handler at a time. For Event Sub-Processes triggered by a Message, the Message correlation behavior is the same as for Receive Tasks -- see Section 13.2.3.
- Only one interrupting Event Handler MAY be initiated for a given EventDefinition within the context of the parent Activity. Once the interrupting Event Handler is started, the parent Activity is interrupted and no new Event Handlers can be initiated or started. An Event Sub-Process completes when all tokens have reached an End Event, like any other Sub-Process. If the parent Activity enters the state Completing, it remains in that state until all contained active Event Sub-Processes have completed. While the parent Activity is in the Completing state, no new Event Sub-Processes can be initiated.
- If an interrupting Event Sub-Process is started by an error, then the parent Activity enters the state Failing and remains in this state until the interrupting Event Handler reaches a final state. During this time, the running Event Handler can access to the context of the parent Activity. However, new Event Handlers MUST NOT be started.
- Similarly, if an interrupting Event Sub-Process is started by a non error (e.g., Escalation), then the parent Activity enters the state Terminating and remains in this state until the interrupting Event Handler reaches a final state. During this time, the running Event Handler can access to the context of the parent Activity. However, new Event Handlers MUST NOT be started.

13.4.5 Compensation

Compensation is concerned with undoing steps that were already successfully completed, because their results and possibly side effects are no longer desired and need to be reversed. If an Activity is still active, it cannot be compensated, but rather needs to be canceled. Cancellation in turn can result in compensation of already successfully completed portions of an active Activity, in case of a Sub-Process.
Compensation is performed by a compensation handler. A compensation handler can either be a Compensation Event Sub-Process (for a Sub-Process or Process), or an associated Compensation Activity (for any Activity). A compensation handler performs the steps necessary to reverse the effects of an Activity. In case of a Sub-Process, its Compensation Event Sub-Process has access to Sub-Process data at the time of its completion (“snapshot data”).

Compensation is triggered by a throw Compensation Event, which typically will be raised by an error handler, as part of cancellation, or recursively by another compensation handler. That Event specifies the Activity for which compensation is to be performed, either explicitly or implicitly.

Compensation Handler

A compensation handler is a set of Activities that are not connected to other portions of the BPMN model. The compensation handler starts with a catch Compensation Event. That catch Compensation Event either is a boundary Event, or, in case of a Compensation Event Sub-Process, the handler’s Start Event.

A compensation handler connected via a boundary Event can only perform “black-box” compensation of the original Activity. This compensation is modeled with a specialized Compensation Activity.

A Compensation Event Sub-Process is contained within a Process or a Sub-Processes. It can access data that is part of its parent, snapshot at the point in time when its parent has completed. A compensation Event Sub-Process can in particular recursively trigger compensation for Activities contained in that its parent.

It is possible to specify that a Sub-Process can be compensated without having to define the compensation handler. The Sub-Process attribute compensable, when set, specifies that default compensation is implicitly defined, which recursively compensates all successfully completed Activities within that Sub-Process, invoking them in reverse order of their forward execution.

Compensation Triggering

Compensation is triggered using a throw Compensation Event, which can either be an Intermediate or an End Event. The Activity which needs to be compensated is referenced. If the Activity is clear from the context, it doesn’t have to be specified and defaults to the current Activity. A typical scenario for that is an inline error handler of a Sub-Process that cannot recover the error, and as a result would trigger compensation for that Sub-Process. If no Activity is specified in a “global” context, all completed Activities in the Process are compensated.

By default, compensation is triggered synchronously, that is, the throw Compensation Event waits for the completion of the triggered compensation handler. Alternatively, compensation can just be triggered without waiting for its completion, by setting the throw Compensation Event’s waitForCompletion attribute to false.

Multiple instances typically exist for Loop or Multi-Instance Sub-Processes. Each of these has its own instance of its Compensation Event Sub-Process, which has access to the specific snapshot data that was current at the time of completion of that particular instance. Triggering compensation for the Multi-Instance Sub-Process individually triggers compensation for all instances within the current scope. If compensation is specified via a boundary compensation handler, this boundary compensation handler also is invoked once for each instance of the Multi-Instance Sub-Process in the current scope.

Relationship between Error Handling and Compensation

Compensation employs a “presumed abort principle”, which has a number of consequences. First, only completed Activities are compensated; compensation of a failed Activity results in an empty operation. Thus, when an Activity fails, i.e., is left because an error has been thrown, it’s the error handler’s responsibility to ensure that no further
compensation will be necessary once the error handler has completed. Second, if no error Event Sub-Process is specified for a particular Sub-Process and a particular error, the default behavior is to automatically call compensation for all contained Activities of that Sub-Process if that error occurs, thus ensuring the “presumed abort” invariant.

Operational Semantics

- A Compensation Event Sub-Process becomes enabled when its parent Activity transitions into state Completed. At that time, a snapshot of the data associated with the parent Activity is taken and kept for later usage by the Compensation Event Sub-Process. In case the parent Activity is a multi-instance or loop, for each instance a separate data snapshot is taken, which is used when its associated Compensation Event Sub-Process is triggered.
- When compensation is triggered for the parent Activity, its Compensation Event Sub-Process is activated and runs. The original context data of the parent Activity is restored from the data snapshot. In case the parent Activity is a multi-instance or loop, for each instance the dedicated snapshot is restored and a dedicated Compensation Event Sub-Process is activated.
- An associated Compensation Activity becomes enabled when the Activity it is associated with transitions into state Completed. When compensation is triggered for that Activity, the associated Compensation Activity is activated. In case the Activity is a multi-instance or loop, the Compensation Activity is triggered only once, too, and thus has to compensate the effects of all instances.
- Default compensation ensures that Compensation Activities are performed in reverse order of the execution of the original Activities, allowing for concurrency when there was no dependency between the original Activities. Dependencies between original Activities that default compensation MUST consider are the following:
- A Sequence Flow between Activities A and B results in compensation of B to be performed before compensation of A.
- A data dependency between Activities A and B, e.g., through an IORules specification in B referring to data produced by A, results in compensation of B to be performed before compensation of A.
- If A and B are two Activities that were active as part of an Ad-Hoc Sub-Process, then compensation of B MUST be performed before compensation of A if A completed before B started.
- Instances of a loop or sequential multi-instance are compensated in reverse order of their forward completion. Instances of a parallel multi-instance can be compensated in parallel.
- If a Sub-Process A has a boundary Event connected to Activity B, then compensation of B MUST be performed before compensation of A if that particular Event occurred. This also applies to multi-instances and loops.

13.4.6 End Events

Process level end events

For a “terminate” End Event, the Process is abnormally terminated—no other ongoing Process instances are affected.

For all other End Events, the behavior associated with the Event type is performed, e.g., the associated Message is sent for a Message End Event, the associated signal is sent for a Signal End Event, and so on. The Process instance is then completed, if and only if the following two conditions hold:

- All start nodes of the Process have been visited. More precisely, all Start Events have been triggered, and for all starting Event-Based Gateways, one of the associated Events has been triggered.
There is no token remaining within the Process instance.

Sub-process level end events

For a “terminate” End Event, the Sub-Process is abnormally terminated. In case of a multi-instance Sub-Process, only the affected instance is terminated—no other ongoing Sub-Process instances or higher-level Sub-Process or Process instances are affected.

For a “cancel” End Event, the Sub-Process is abnormally terminated and the associated transaction is aborted. Control leaves the Sub-Process through a cancel intermediate boundary Event.

For all other End Events, the behavior associated with the Event type is performed, e.g., the associated Message is sent for a Message End Event, the associated signal is sent for a signal End Event, and so on. The Sub-Process instance is then completed, if and only if the following two conditions hold:

◆ All start nodes of the Sub-Process have been visited. More precisely, all Start Events have been triggered, and for all starting Event-Based Gateways, one of the associated Events has been triggered.

◆ There is no token remaining within the Sub-Process instance.
14 Mapping BPMN Models to WS-BPEL

Note – The contents of this chapter is REQUIRED for BPMN BPEL Process Execution Conformance or for BPMN Complete Conformance. However, this chapter is NOT REQUIRED for BPMN Process Modeling Conformance, BPMN Process Choreography Conformance, or BPMN Process Execution Conformance. For more information about BPMN conformance types, see page 2.

This chapter covers a mapping of a BPMN model to WS-BPEL that is derived by analyzing the BPMN objects and the relationships between these objects.

A Business Process Diagram can be made up of a set of (semi-)independent components, which are shown as separate Pools, each of which represents an orchestration Process. There is not a specific mapping of the diagram itself, but rather, each of these orchestration Processes maps to an individual WS-BPEL process.

Not all BPMN orchestration Processes can be mapped to WS-BPEL in a straightforward way. That is because BPMN allows the modeler to draw almost arbitrary graphs to model control flow, whereas in WS-BPEL, there are certain restrictions such as control-flow being either block-structured or not containing cycles. For example, an unstructured loop cannot directly be represented in WS-BPEL.

To map a BPMN orchestration Process to WS-BPEL it MUST be sound, that is it MUST contain neither a deadlock nor a lack of synchronization. A deadlock is a reachable state of the Process that contains a token on some Sequence Flow that cannot be removed in any possible future. A lack of synchronization is a reachable state of the Process where there is more than one token on some Sequence Flow. For further explanation of these terms, we refer to the literature.

To define the structure of BPMN Processes, we introduce the following concepts and terminology. The Gateways and the Sequence Flows of the BPMN orchestration Process form a directed graph. A block of the diagram is a connected sub-graph that is connected to the rest of the graph only through exactly two Sequence Flows: exactly one Sequence Flow entering the block and exactly one Sequence Flow leaving the block. A block hierarchy for a Process model is a set of blocks of the Process model in which each pair of blocks is either nested or disjoint and which contains the maximal block (i.e. the whole Process model) A block that is nested in another block B is also called a subblock of B (cf. Figure 14.1). Each block of the block hierarchy of a given BPMN orchestration Process has a certain structure (or pattern) which provides the basis for defining the BPEL mapping.
The following sections define a syntactical BPEL mapping prescribing the resulting BPEL model at the syntactical level, and a semantic BPEL mapping prescribing the resulting BPEL model in terms of its observable behavior. The syntactical BPEL mapping is defined for a subset of BPMN models based on certain patterns of BPMN blocks, whereas the semantical BPEL mapping (which extends the syntactical mapping) does not enforce block patterns, allowing for the mapping a larger class of BPMN models without prescribing the exact syntactical representation in BPEL.

### 14.1 Basic BPMN-BPEL Mapping

This section introduces a partial mapping function from BPMN orchestration Process models to WS-BPEL executable Process models by recursively defining the mapping for elementary BPMN constructs such as Tasks and Events, and for blocks following the patterns described here. Mapping a BPMN block to WS-BPEL includes mapping all of its associated attributes. The observable behavior of a WS-BPEL process resulting from a BPEL mapping is the same as that of the original BPMN orchestration Process.

We use the notation [BPMN construct] to denote the WS-BPEL construct resulting from mapping the BPMN construct. Examples are

\[
\text{[ServiceTask]} = \text{Invoke Activity}
\]

which says that a BPMN Service Task is mapped to a WS-BPEL Invoke Activity, or
which says that the data-based exclusive choice controlled by the two predicates p1 and p2, containing the three BPMN blocks G1, G2 and G3 is mapped to the WS-BPEL on the right hand side, which recursively uses the mappings of those predicates and those sub-graphs. Note that we use the “waved rectangle” symbol throughout this section to denote BPMN blocks.

### 14.1.1 Process

The following figure describes the mapping of a Process, represented by its defining Collaboration, to WS-BPEL. The process itself is described by a contained graph G of flow elements) to WS-BPEL. The Process interacts with Participants Q1…Qn via Conversations C1…Cm:

![BPMN Process Diagram](image)

```xml
<process name="[P-name]"
  targetNamespace="[targetNamespace]"
  expressionLanguage="[expressionLanguage]"
  suppressJoinFailure="yes"
  xmlns="http://docs.oasis-open.org/wsbpel/2.0/process/executable">
  <partnerLinks>
    [ {P-Interfaces} UNION {Qi-Interfaces} ]
  </partnerLinks>
  <variables>
    [ {dataObjects} UNION {properties} ]
  </variables>
  <correlationSets>
    [ {Cj-CorrelationKeys} ]
  </correlationSets>
  [G]
</process>
```

The partner links of the corresponding WS-BPEL process are derived from the set of interfaces associated with each participant. Each interface of the Participant containing the Process P itself is mapped to a WS-BPEL partner link with a “myRole” specification, each interface of each other Participant Qi is mapped to a WS-BPEL partner link with a “partnerRole” specification.
The variables of the corresponding WS-BPEL process are derived from the set “{dataObjects}” of all Data Objects occurring within G, united with the set “{properties}” of all properties occurring within G, without Data Objects or properties contained in nested Sub-Processes. See Section “Handling Data” on page 481 for more details of this mapping.

The correlation sets of the corresponding WS-BPEL process are derived from the CorrelationKeys of the set of Conversations C1…Cn.. See page 466 for more details of this mapping.

14.1.2 Activities
Common Activity Mappings

The following table displays a set of mappings of general BPMN Activity attributes to WS-BPEL activity attributes.

<table>
<thead>
<tr>
<th>Activity</th>
<th>Mapping to WS-BPEL</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name attribute of a BPMN activity is mapped to the name attribute of a WS-BPEL activity by removing all characters not allowed in an XML NCName, and ensuring uniqueness by adding an appropriate suffix. In the subsequent diagrams, this mapping is represented as [name].</td>
</tr>
</tbody>
</table>

Task Mappings

The following sections contain the mappings of the variations of a Task to WS-BPEL.

Service Task

The following figure shows the mapping of a Service Task to WS-BPEL:

![Service Task diagram]

<invoke name="[Task-name]"
  partnerLink="[Q, Task-operation-interface]"
  portType="[Task-operation-interface]"
  operation="[Task-operation]">
</invoke>

The partner link associated with the WS-BPEL invoke is derived from both the participant Q that the Service Task is connected to by Message Flows, and from the interface referenced by the operation of the Service Task.

Receive Task

The following figure shows the mapping of a Receive Task to WS-BPEL:
The partner link associated with the WS-BPEL receive is derived from the interface referenced by the operation of the Receive Task.

Send Task

The following figure shows the mapping of a Send Task to WS-BPEL:

\[
<\text{invoke} \text{name}="\{\text{Task-name}\}"
\text{partnerLink}="[Q, \text{Task-operation-interface}]"
\text{portType}="[\text{Task-operation-interface}]"
\text{operation}="[\text{Task-operation}]">
</\text{invoke}>
\]

The partner link associated with the WS-BPEL invoke is derived from both the participant Q that the Send Task is connected to by a Message Flow, and from the interface referenced by the operation of the Send Task.

Abstract Task

The following figure shows the mapping of an Abstract Task to WS-BPEL:

\[
<\text{empty} \text{name}="[\text{Task-name}]">
</\text{empty}>
\]

Service Package

Message

For Messages with a scalar data item definition typed by an XML schema definition, the following figure shows the mapping to WS-BPEL, using WSDL 1.1:
The top-level child elements of the XML schema defining the structure of the BPMN Message are mapped to the WSDL’s message’s parts.

Interface and Operation

The following figure shows the mapping of a BPMN interface with its operations to WS-BPEL, using WSDL 1.1:

Conversations and Correlation

For those BPMN nodes sending or receiving Messages (i.e., Message Events, Service, send or Receive Tasks) that have an associated key-based Correlation Key, the mapping of that key-based Correlation Key is as follows:
The `messageType` of the BPEL property alias is appropriately derived from the `itemDefinition` of the `Message` referenced by the BPMN `Message` key `Expression`. The name of the `Message` part is derived from the `Message` key `Expression`. The `Message` key `Expression` itself is transformed into an `Expression` relative to that part.

The mapping of `Activities` with an associated key-based `Correlation Key` is extended to reference the above BPEL correlation set in the corresponding BPEL `correlations` element. The following figure shows that mapping in the case of a `Service Task` with an associated key-based `Correlation Key`.

The initiate attribute of the BPEL `correlation` element is set depending on whether or not the associated `Message Flow` initiates the associated `Conversations`, or participates in an already existing `Conversation`. If there are multiple `CorrelationKeys` associated with the `Conversation`, multiple `correlation` elements are used.

**Sub-Process Mappings**

The following table displays the mapping of an embedded `Sub-Process` with `Adhoc"False"` to a WS-BPEL scope. (This extends the mappings that are defined for all `Activities`—see page 464):

The following figure shows the mapping of a BPMN `Sub-Process` without an Event `Sub-Process`:
The following figure shows the mapping of a BPMN Sub-Process with an Event Sub-Process. (Event Sub-Processes could also be added to a top-level Process, in which case their mapping extends correspondingly.)

Note that in case of multiple Event Sub-Processes, there would be multiple WS-BPEL handlers.

Mapping of Event Sub-Processes

Note that if a Sub-Process contains multiple Event Sub-Processes, all become handlers of the associated WS-BPEL scope, ordered and grouped as specified by WS-BPEL.

Non-interrupting Message Event Sub-Processes are mapped to WS-BPEL event handlers as follows:

Timer Event Sub-Processes are mapped to WS-BPEL event handlers as follows:

Error Event Sub-Processes are mapped to WS-BPEL fault handlers as follows:
A Compensation Event Sub-Process is mapped to a WS-BPEL compensation handler as follows:

\[
\text{Compensation} = \begin{cases} 
\text{\langle compensationHandler \rangle } \\
\text{\langle G \rangle } \\
\text{\textbackslash /\text{\langle compensationHandler \rangle } }
\end{cases}
\]

Activity Loop Mapping

Standard loops with a testTime attribute “Before” or “After” execution of the Activity map to WS-BPEL while and repeatUntil activities in a straight-forward manner. When the LoopMaximum attribute is used, additional activities are used to maintain a loop counter.

Multi-instance Activities map to WS-BPEL forEach activities in a straight-forward manner.

Standard Loops

The mappings for standard loops to WS-BPEL are described in the following.

A standard loop with testTime= “Before” maps as follows, where \( p \) denotes the loop condition:

\[
\text{\textbackslash \text{Task}} = \begin{cases} 
\text{\langle\text{\while} \rangle } \\
\text{\langle\text{\condition} \rangle}[p]\text{\langle/\text{\condition}\rangle } \\
\text{\textbackslash [\text{\Task} ] } \\
\text{\langle/\text{\while} \rangle }
\end{cases}
\]

A standard loop with testTime= “After” maps as follows, where \( p \) denotes the loop condition:

\[
\text{\textbackslash \text{Task}} = \begin{cases} 
\text{\langle\text{\repeatUntil} \rangle } \\
\text{\textbackslash [\text{\Task} ] } \\
\text{\langle\text{\condition} \rangle}[\text{\not p}]\text{\langle/\text{\condition}\rangle } \\
\text{\langle/\text{\repeatUntil} \rangle }
\end{cases}
\]

Dealing with LoopMaximum

When the LoopMaximum attribute is specified for an Activity, the loop requires additional set up for maintaining a counter.
A standard loop with testTime="Before" and a LoopMaximum attribute maps to WS-BPEL as follows (again, p denotes the loopCondition):

```xml
<variable name="\[counter\]" type="xsd:integer"/>
...
<sequence>
<assign>
<copy>
from \[literal\]0\[/literal]\</from>
<to variable="\[counter\]"/>
</copy>
</assign>
<while>
<condition>p and \[counter\] &lt; \[LoopMaximum\]</condition>
<sequence>
\[G\]
<assign>
<copy>
from expression="\[counter\]+1"/>  
<to variable="\[counter\]"/>
</copy>
</assign>
</sequence>
</while>
</sequence>

(The notation \[counter\] denotes the unique name of a variable used to hold the counter value; the actual name is immaterial.)

A standard loop with testTime="After" and a LoopMaximum attribute maps as follows:

```xml
<variable name="\[counter\]" type="xsd:integer"/>
...
<sequence>
<assign>
<copy>
from \[literal\]0\[/literal]\</from>
<to variable="\[counter\]"/>
</copy>
</assign>
<repeatUntil>
<sequence>
\[G\]
<assign>
<copy>
from expression="\[counter\]+1"/>  
<to variable="\[counter\]"/>
</copy>
</assign>
</sequence>
<condition>\[not\] p or \$\[counter\] &gt; \[LoopMaximum\]</condition>
</repeatUntil>
</sequence>
```
Multi-Instance Activities

A BPMN Multi-Instance Task with a multiInstanceFlowCondition of “All” is mapped to WS-BPEL as follows:

```
<variable name="[counter}" type="xsd:integer"/>
...  
<forEach counterName="[counter]" parallel="[isSequential? 'no':'yes']">
  <startCounterValue>1</startCounterValue>
  <finalCounterValue>[condition]</finalCounterValue>
  <scope>
    <Task>
    </Task>
  </scope>
</forEach>
<receive name="[e-name]" createInstance="yes" partnerLink="[e-operation-interface]"
  portType="[e-operation-interface]" operation="[e-operation]">
  <![CDATA[]]>
</receive>
```

(The notation `[counter]` denotes the unique name of a variable used to hold the counter value; the actual name is immaterial.)

14.1.3 Events

Start Event Mappings

The following sections detail the mapping of Start Events to WS-BPEL.

Message Start Events

A Message Start Event is mapped to WS-BPEL as shown in the following figure:

```
<receive name="[e-name]"
  createInstance="yes"
  partnerLink="[e-operation-interface]"
  portType="[e-operation-interface]"
  operation="[e-operation]">
  <![CDATA[]]>
</receive>
```

The partner link associated with the WS-BPEL receive is derived from the interface referenced by the operation of the Message Start Event.

Error Start Events

An Error Start Event can only occur in Event Sub-Processes. This mapping is described on page 468.

Compensation Start Events

A Compensation Start Event can only occur in Event Sub-Processes. This mapping is described page 468.
Intermediate Event Mappings (Non-boundary)

The following sections detail the mapping of intermediate non-boundary Events to WS-BPEL.

Message Intermediate Events (Non-boundary)

A Message Intermediate Event can either be used in normal control flow, similar to a Send or Receive Task (for throw or catch Message Intermediate Events, respectively), or it can be used in an Event Gateway. The latter is described in more detail in 14.1.4, 'Gateways and Sequence Flows'.

The following figure describes the mapping of Message Intermediate Events to WS-BPEL:

![Diagram of Message Intermediate Events to WS-BPEL]

The partner link associated with the WS-BPEL receive is derived from the interface referenced by the operation of the Message Intermediate Event.

Timer Intermediate Events (Non-boundary)

A Timer Intermediate Event can either be used in normal control flow, or it can be used in an Event Gateway. The latter is described in more detail in 14.1.4, 'Gateways and Sequence Flows'.

The following figure describes the mapping of a Timer Intermediate Event to WS-BPEL – note that one of the mappings shown is chosen depending on whether the Timer Event's TimeCycle or TimeDate attribute is used:

![Diagram of Timer Intermediate Events to WS-BPEL]

Compensation Intermediate Events (Non-boundary)

A Compensation Intermediate Event with its waitForCompletion property set to true, that is used within an Event Sub-Process triggered through an error or through compensation, is mapped to WS-BPEL as follows:
The first mapping is used if the Compensation Event does not reference an Activity, the second mapping is used otherwise.

End Event Mappings

The following sections detail the mapping of End Events to WS-BPEL.

None End Events

A “none” End Event marking the end of a Process is mapped to WS-BPEL as shown in the following figure:

The partner link associated with the WS-BPEL invoke is derived from both the participant Q that the Message Intermediate Event is connected to by a Message Flow, and from the interface referenced by the operation of the Message Intermediate Event.

Error End Events

An Error End Event is mapped to WS-BPEL as shown in the following figure:
Compensation End Events

A Compensation End Event with its `waitForCompletion` property set to `true`, that is used within an Event Sub-Process triggered through an `error` or through `compensation`, is mapped to WS-BPEL as follows:

```xml
[  ]

  =  <throw faultName="[e-name]">
     =  </throw>
``` 

The first mapping is used if the Compensation Event does not reference an Activity, the second mapping is used otherwise.

Terminate End Events

A Terminate End Event is mapped to WS-BPEL as shown in the following figure:

```xml
[  ]

  =  <exit>
     =  </exit>
``` 

Boundary Intermediate Events

Message Boundary Events

A BPMN Activity with a non-interrupting Message boundary Event is mapped to a WS-BPEL scope with an event handler as follows:
The partner link associated with the WS-BPEL onEvent is derived from the interface referenced by the operation of the boundary **Message Event**.

The same mapping applies to a non-interrupting boundary **Timer Event**, using a WS-BPEL onAlarm handler instead.

**Error Boundary Events**

A **BPMN Activity** with a boundary **Error Event** according to the following pattern is mapped as shown:

```
<flow>
  <links>
    <link name="[l1]"/>
    ...
    <link name="[l4]"/>
  </links>
  <scope>
    <sources><source linkName="[l1]"/></sources>
    <faultHandlers>
      <catch faultName="[e-error]">
        <empty>
          <sources><source linkName="[l3]"/></sources>
        </empty>
      </catch>
    </faultHandlers>
  </scope>
  <flow>
    <targets><target linkName="[l1]"/></targets>
    <sources><source linkName="[l2]"/></sources>
  </flow>
  <flow>
    <targets><target linkName="[l3]"/></targets>
    <sources><source linkName="[l4]"/></sources>
  </flow>
  <empty>
    <sources><source linkName="[l2]"/>
    <source linkName="[l4]"/></sources>
  </empty>
  <flow>
```

![Diagram of BPMN Activity with Error Event](image)
Note that the case where the error handling path doesn’t join the main control flow again, is still mapped using this pattern, by applying the following model equivalence:

![Diagram showing compensation boundary events](image)

**Compensation Boundary Events**

A BPMN Activity with a boundary Compensation Event is similarly mapped as shown:

```xml
<scope name="[Activity-name]">
  <compensationHandler>
    [G]
  </compensationHandler>
  <Activity>
  </Activity>
</scope>
```

**Multiple Boundary Events, and Boundary Events with Loops**

If there are multiple boundary Events for an Activity, their WS-BPEL mappings are super-imposed on the single WS-BPEL scope wrapping the mapping of the Activity.

When the Activity is a standard loop or a multi-instance and has one or more boundary Events, the WS-BPEL loop resulting from mapping the BPMN loop is nested inside the WS-BPEL scope resulting from mapping the BPMN boundary Events.

The following example shows that mapping for a Sub-Process with a nested Event Sub-Process that has a standard loop with `TestTime=“Before,”` a boundary Error Intermediate Event, and a boundary Compensation Intermediate Event.
14.1.4 Gateways and Sequence Flows

The mapping of BPMN Gateways and Sequence Flows is described using BPMN blocks following particular patterns.

**Exclusive (Data-based) Decision Pattern**

An exclusive data-based decision is mapped as follows:

```xml
<flow>
<links>
  <link name="[l1]"/>
  ...
  <link name="[l4]"/>
</links>
<scope>
  <sources><source linkName="[l1]"/></sources>
  <faultHandlers>
    <catch faultName="[e-error]">
      <empty>
        <sources><source linkName="[l3]"/></sources>
      </empty>
    </catch>
  </faultHandlers>
  <compensationHandler>
    [G3]
  </compensationHandler>
  <while>
    <condition>[p]</condition>
    <scope>
      [Handler]
      [G]
    </scope>
  </while>
</scope>
<flow>
  <targets><target linkName="[l1]"/></targets>
  <sources><source linkName="[l2]"/></sources>
</flow>
<flow>
  <targets><target linkName="[l3]"/></targets>
  <sources><source linkName="[l4]"/></sources>
</flow>
<empty>
  <sources><source linkName="[l2]"/>
  <source linkName="[l4]"/></sources>
</empty>
</flow>
```
While this figure shows three branches, the pattern is generalized to $n$ branches in an obvious manner.

**Exclusive (Event-based) Decision Pattern**

An **Event Gateway** is mapped as follows:

While this figure shows three branches with one **Message Intermediate Event**, one **Receive Task** and one **Timer Intermediate Event**, the pattern is generalized to $n$ branches with any combination of the former in an obvious manner. The handling of **Participants** (BPEL partnerLinks), **Event** (operation) and timer details is as specified for **Message Intermediate Events**, **Receive Tasks**, and **Timer Intermediate Events**, respectively. The data flow and associated variables (not shown) are handled as for **Receive Tasks/Message Intermediate Events**.

**Inclusive Decision Pattern**

An inclusive decision pattern without an otherwise gate is mapped as follows:
While this figure shows three branches, the pattern is generalized to $n$ branches in an obvious manner.

Note that link names in WS-BPEL MUST follow the rules of an XML NCName. Thus, the mapping of the BPMN Sequence Flow name attribute MUST appropriately canonicalize that name, possibly ensuring uniqueness, e.g., by appending a unique suffix. This is capture by the [linkName] notation.
Parallel Pattern

A parallel fork-join pattern is mapped as follows:

Sequence Pattern

A BPMN block consisting of a series of Activities connected via (unconditional) Sequence Flows is mapped to a WS-BPEL sequence:

Structured Loop Patterns

A BPMN block consisting of a structured loop of the following pattern is mapped to a WS-BPEL while:

A BPMN block consisting of a structured loop of the following pattern is mapped to a WS-BPEL repeatUntil:
Handling Loops in Sequence Flows

Loops are created when the flow of the Process moves from a downstream object to an upstream object. There are two types of loops that are WS-BPEL mappable: while loops and repeat loops.

A while loop has the following structure in BPMN and is mapped as shown:

```
<while>
  <condition>[p]</condition>
  [G]
</while>
```

A repeat loop has the following structure in BPMN and is mapped as shown:

```
<repeatUntil>
  [G]
  <condition>[not p]</condition>
</repeatUntil>
```

14.1.5 Handling Data

Data Objects

BPMN Data Objects are mapped to WS-BPEL variables. The itemDefinition of the Data Object determines the XSD type of that variable.

Data Objects occur in the context of a Process or Sub-Process. For the associated WS-BPEL process or WS-BPEL scope, a variable is added for each Data Object in the corresponding WS-BPEL variables section, as follows:
Properties

BPMN properties can be contained in a Process, Activity, or an Event, here named the “container” of the property. A BPMN property is mapped to a WS-BPEL variable. Its name is derived from the name of its container and the name of the property. Note that in the case of different containers with the same name and a contained property of the same name, the mapping to WS-BPEL ensures the names of the associated WS-BPEL variables are unique. The itemDefinition of the property determines the XSD type of that variable.

A BPMN Process property is mapped to a WS-BPEL global variable. A BPMN Event property is mapped to a WS-BPEL variable contained in the WS-BPEL scope representing the immediately enclosing Sub-Process of the Event (or a global variable in case the Event is an immediate child of the Process). For a BPMN Activity property, two cases are distinguished: In case of a Sub-Process, the WS-BPEL variable is contained in the WS-BPEL scope representing the Sub-Process. For all other BPMN Activity properties, the WS-BPEL variable is contained in the WS-BPEL scope representing the immediately enclosing Sub-Process of the Activity (or a global variable in case the Activity is an immediate child of the Process).

Input and Output Sets

For a Send Task and a Service Task, the single input set is mapped to a WSDL message defining the input of the associated WS-BPEL activity. The inputs map to the message parts of the WSDL message. For a Receive Task and a Service Task, the single output set is mapped to a WSDL message defining the output of the associated WS-BPEL activity. The outputs map to the message parts of the WSDL message.

The structure of the WSDL message is defined by the itemDefinitions of the data inputs of the input set:
For the data outputs of the output set, the WSDL message looks as follows:

```
<wsdl:message name="[iset-name]">
  <part name="[input1-name]" type="[type1]"/>
  ...
</wsdl:message>
```

Data Associations

In this section, we assume that the input set of the **Service Task** has the same structure as its referenced input **Message**, and the output set of the **Service Task** has the same structure as its reference output **Message**. If this is not the case, assignments are needed, and the mapping is as described in the next section.

Data associations to and from a **Service Task** are mapped as follows:

```
<invoke ...
  <toParts>
    <toPart part="[dataInput1-name]" fromVariable="[D1-name]"/>
    <toPart part="[dataInput2-name]" fromVariable="[D2-name]"/>
  </toParts>
  <fromParts>
    <fromPart part="[dataOutput1-name]" fromVariable="[D3-name]"/>
    <fromPart part="[dataOutput2-name]" fromVariable="[D4-name]"/>
  </fromParts>
</invoke>
```

Data associations from a **Receive Task** are mapped as follows:
Data associations to a **Send Task** are mapped as follows:

Expressions

**BPMN Expressions** specified using XPath (e.g., a condition **Expression** of a **Sequence Flow**, or a timer cycle **Expression** of a **Timer Intermediate Event**) are used as specified in **BPMN**, rewriting access to **BPMN** context to refer to the mapped BPEL context.

The **BPMN** XPath functions for accessing context from the perspective of the current **Process** are mapped to BPEL XPath functions for context access as shown in the following table. This is possible because the arguments MUST be literal strings.

**Table 14.2 - Expressions mapping to WS-BPEL**

<table>
<thead>
<tr>
<th>BPMN context access</th>
<th>BPEL context access</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getDataObject(dataObjectName)</code></td>
<td><code>[$dataObjectName]</code></td>
</tr>
<tr>
<td><code>getProcessProperty(propertyName)</code></td>
<td><code>${[processName].propertyName}</code> where the right process-Name is statistically derived.</td>
</tr>
<tr>
<td><code>getActivityProperty(activityName, propertyName)</code></td>
<td><code>$[activityName.propertyName]</code></td>
</tr>
<tr>
<td><code>getEventProperty(eventName, propertyName)</code></td>
<td><code>$[eventName.propertyName]</code></td>
</tr>
</tbody>
</table>
Assignments

For a **Service Task** with assignments, the WS-BPEL mapping results in a sequence of an assign activity, an invoke activity and another assign activity. The first assign deals with creating the service request **Message** from the data inputs of the **Task**, the second assign deals with creating the data outputs of the **Task** from the service response **Message**.

### 14.2 Extended BPMN-BPEL Mapping

Additional sound **BPMN Process** models whose block hierarchy contains blocks that have not been addressed in the previous section can be mapped to WS-BPEL. For such **BPMN Process** models, in many cases there is no preferred single mapping of a particular block, but rather, multiple WS-BPEL patterns are possible to map that block to. Also, additional **BPMN** constructs can be mapped by using capabilities not available at the time of producing this specification, such as the upcoming OASIS BPEL4People standard to map **BPMN User Tasks**, or other WS-BPEL extensions.

Rather than describing or even mandating the mapping of such **BPMN** blocks, this specification allows for a semantic mapping of a **BPMN Process** model to an executable WS-BPEL process: The observable behavior of the target WS-BPEL process **MUST** match the operational semantics of the mapped **BPMN Process**. Also, the mappings described in Section 15.1 **SHOULD** be used where applicable.

#### 14.2.1 End Events

**End Events** can be combined with other **BPMN** objects to complete the merging or joining of the paths of a WSBPEL structured element (see Figure 7.3).

![Figure 14.2 - An example of distributed token recombination](image)
14.2.2 Loop/Switch Combinations From a Gateway

This type of loop is created by a Gateway that has three or more outgoing Sequence Flows. One Sequence Flow loops back upstream while the others continue downstream (see Figure 14.3). Note that there might be intervening Activities prior to when the Sequence Flow loops back upstream.

- This maps to both a WSBPEL while and a switch. Both activities will be placed within a sequence, with the while preceding the switch.
- For the while:
  - The Condition for the Sequence Flow that loops back upstream will map to the condition of the while.
  - All the Activities that span the distance between where the loop starts and where it ends, will be mapped and placed within the Activity for the while, usually within a sequence.
- For the switch:
  - For each additional outgoing Sequence Flows there will be a case for the switch.

![Figure 14.3 - An example of a loop from a decision with more than two alternative paths](image)

14.2.3 Interleaved Loops

This is a situation where there at least two loops involved and they are not nested (see Figure 14.4). Multiple looping situations can map, as described above, if they are in a sequence or are fully nested (e.g., one while inside another while). However, if the loops overlap in a non-nested fashion, as shown in the figure, then the structured element while cannot be used to handle the situation. Also, since a flow is acyclic, it cannot handle the behavior either.
To handle this type of behavior, parts of the WSBPEL process will have to be separated into one or more derived processes that are spawned from the main process and will also spawn or call each other (note that the examples below are using a spawning technique). Through this mechanism, the linear and structured elements of WSBPEL can provide the same behavior that is shown through a set of cycles in a single BPMN diagram. To do this:

- The looping section of the Process, where the loops first merge back (upstream) into the flow until all the paths have merged back to Normal Flow, SHALL be separated from the main WSBPEL process into a set of derived processes that will spawn each other until all the looping conditions are satisfied.

- The section of the process that is removed will be replaced by a (one-way) invoke to spawn the derived process, followed by a receive to accept the message that the looping sections have completed and the main process can continue (see Figure 14.5).

- The name of the invoke will be in the form of:
  - “Spawn_[(loop target)activity.Name]_Derived_Process”

- The name of the receive will be in the form of:
  - “[{(loop target)activity.Name]_Derived_Process_Completed”

Figure 14.4 - An example of interleaved loops
For each location in the Process where a Sequence Flow connects upstream, there will be a separate derived WSBPEL process.

- The name of the derived process will be in the form of:
  - “[(loop target)activity.Name]_Derived_Process”

- All Gateways in this section will be mapped to switch elements, instead of while elements (see Figure below).

- Each time there is a Sequence Flow that loops back upstream, the Activity for the switch case will be a (one-way) invoke that will spawn the appropriate derived process, even if the invoke spawns the same process again.

- The name of the invoke will be the same as the one describe above.

- At the end of the derived process a (one-way) invoke will be used to signal the main process that all the derived activities have completed and the main process can continue.

- The name of the invoke will be in the form of:
  - “[(loop target)activity.Name]_Derived_Process_Completed”
14.2.4 Infinite Loops

This type of loop is created by a Sequence Flow that loops back without an intervening Gateway to create alternative paths (see Figure 14.7). While this can be a modeling error most of the time, there can be situations where this type of loop is desired, especially if it is placed within a larger Activity that will eventually be interrupted.

- This will map to a while activity.
- The condition of the while will be set to an Expression that will never evaluate to true, such as condition ”1 = 0.”
- All the activities that span the distance between where the loop starts and where it ends, will be mapped and placed within the activity for the while, usually within a sequence.

Figure 14.7 - An example – An infinite loop

14.2.5 BPMN Elements that Span Multiple WSBPEL Sub-Elements

Figure 14.8 below illustrates how BPMN objects can exist in two separate sub-elements of a WSBPEL structured element at the same time. Since BPMN allows free form connections of Activities and Sequence Flows, it is possible that two (or more) Sequence Flows will merge before all the Sequence Flows that map to a WSBPEL structure element have merged. The sub-elements of a WSBPEL structured elements are also self-contained and there is no cross sub-element flow. For example, the cases of a switch cannot interact; that is, they cannot share activities. Thus, one BPMN Activity will need to appear in two (or more) WSBPEL structured elements. There are two possible mechanisms to deal with the situation:

- First, the activities are simply duplicated in all appropriate WSBPEL elements.
- Second, the activities that need to be duplicated can be removed from the main Process and placed in a derived process that is called (invoked) from all locations in the WSBPEL elements as needed.
  - The name of the derived process will be in the form of:
  - “[target)object.Name]_Derived_Process”
Figure 14.8 below displays this issue with an example. In that example, two **Sequence Flows** merge into the “Include History of Transactions” **Task**. However, the Decision that precedes the **Task** has three (3) alternatives. Thus, the Decision maps to a WSBPEL **switch** with three (3) **cases**. The three **cases** are not closed until the “Include Standard Text” **Task**, downstream. This means that the “Include History of Transactions” **Task** will actually appear in two (2) of the three (3) **cases** of the **switch**.

**Note** – the use of a WSBPEL **flow** will be able to handle the behavior without duplicating activities, but a **flow** will not always be available for use in these situations, particularly if a WSBPEL **pick** is requested.

![Diagram](image.png)

**Figure 14.8 - An example - Activity that spans two paths of a WSBPEL structured element**
15 Exchange Formats

15.1 Interchanging Incomplete Models

In practice, it is common for models to be interchanged before they are complete. This occurs frequently when doing iterative modeling, where one user (such as a subject matter expert or business person) first defines a high-level model, and then passes it on to another user to be completed and refined.

Such "incomplete" models are ones in which all of the mandatory attributes have not yet been filled in, or the cardinality lowerbound of attributes and associations has not been satisfied.

XMI allows for the interchange of such incomplete models. In BPMN, we extend this capability to interchange of XML files based on the BPMN XSD. In such XML files, implementers are expected to support this interchange by:

- Disregarding missing attributes that are marked as 'required' in the XSD.
- Reducing the lower bound of elements with 'minOccurs' greater than 0.

15.2 Machine Readable Files

BPMN 2.0 machine readable files, including XSD, XMI and XSLT files can be found in OMG Document DTC/2010-05-04, which is a zip file containing all the files:

- XSD files are found under the XSD folder of the zip file, and the main file is XSD/BPMN20.xsd.
- XMI files are found under the XMI folder of the zip file, and the main file is XSD/BPMN20.cmoF.
- XSLT files are found under the XSLT folder of the zip file.

15.3 XSD

15.3.1 Document Structure

A domain-specific set of model elements is interchanged in one or more BPMN files. The root element of each file MUST be <bpmn:definitions>. The set of files MUST be self-contained, i.e. all definitions that are used in a file MUST be imported directly or indirectly using the <bpmn:import> element.

Each file MUST declare a "targetNamespace" which MAY differ between multiple files of one model.

BPMN files MAY import non-BPMN files (such as XSDs and WSDLs) if the contained elements use external definitions.

Example:

```xml
<?xml version="1.0" encoding="UTF-8"?>
    targetNamespace="sample1.main" xmlns:main="sample1.main" xmlns:s1="sample1.semantic1">
    <bpmn:import location="semantic1.bpmn" namespace="sample1.semantic1"
```
15.3.2 References within the BPMN XSD

All BPMN elements contain IDs and within the BPMN XSD, references to elements are expressed via these IDs. The XSD IDREF type is the traditional mechanism for referencing by IDs, however it can only reference an element within the same file. The BPMN XSD supports referencing by ID, across files, by utilizing QNames. A QName consists of two parts: an optional namespace prefix and a local part. When used to reference a BPMN element, the local part is expected to be the ID of the element.

For example, consider the following Process

  <process name="Patient Handling" id="Patient_Handling_Process_ID1"> ... </process>

When this Process is referenced from another file, the reference would take the following form:

  processRef="process_ns:Patient_Handling_Process_ID1"
where "process_ns" is the namespace prefix associated with the process namespace upon import, and "Patient_Handling_Process_ID1" is the value of the id attribute for the Process.

The BPMN XSD utilizes IDREFs wherever possible and resorts to QName only when references can span files. In both situations however, the reference is still based on IDs.

15.4 XMI

XMI allows the use of tags to tailor the documents that are produced using XMI. The following tags have been explicitly set for serializing BPMN 2.0 models; the others are left at their default values:

- tag nsURI set to "http://www.omg.org/spec/BPMN/20100524/XMI"
- tag nsPrefix set to "bpmn"

The BPMN 2.0 XMI for the interchange of diagram information will be published once the OMG Diagram Definition RFP process has produced a specification that is sufficiently complete such that a future BPMN RFP/FTF/RTF can align the BPMN specification with the Diagram Definition specification.

15.5 XSLT Transformation between XSD and XMI

- The XSLT transformation from XSD to XMI is in the file XSLT/BPMN20-ToXMI.xslt
- The XSLT transformation from XMI to XSD is in the file XSLT/BPMN20-FromXMI.xslt
Annex A: Changes from v1.2

(informative)

A.1 Changes from BPMN, v1.2

There have been notational and technical changes to the BPMN specification.

The major notational changes include:

- The addition of a Choreography diagram
- The addition of a Conversation diagram
- Non-interrupting Events for a Process
- Event Sub-Processes for a Process

The major technical changes include:

- A formal metamodel as shown through the class diagram figures
- Interchange formats for abstract syntax model interchange in both XMI and XSD
- Interchange formats for diagram interchange in both XMI and XSD
- XSLT transformations between the XMI and XSD formats

Other technical changes include:

- Reference Tasks are removed. These provided reusability within a single diagram, as compared to GlobalTasks, which are reusable across multiple diagrams. GlobalTasks can be used instead of Reference Tasks, to simplify the language and implementations."
Annex B: Diagram Interchange

(non-normative)

B.1 Scope

This annex provides documentation for a relevant subset of an alpha version of a Diagram Definition (DD) specification that is being referenced by this specification (in section 13 - BPMN DI). The (complete version of the) DD specification is still going through a separate submission/approval process and once finalized and adopted, a future revision of this specification may replace this annex by a reference to that adopted DD specification.

The Diagram Definition specification provides a basis for modeling and interchanging graphical notations, specifically node and edge style diagrams as found in BPMN, UML and SysML, for example, where the notations are tied to abstract language syntaxes defined with MOF. The specification addresses the requirements in the Diagram Definition RFP (ad/2007-09-02).

B.2 Architecture

The DD architecture distinguishes two kinds of graphical information, depending on whether language users have control over it. Graphics that users have control over, such as position of nodes and line routing points, are captured for interchange between tools. Graphics that users do not have control over, such as shape and line styles defined by language standards are not interchanged because they are the same in all diagrams conforming to the language. The DD architecture has two models to enable specification of these two kinds of graphical information, Diagram Interchange (DI) and Diagram Graphics (DG).(both models share common elements from a Diagram Common (DC) model). The DI and DG models are shown in Figure B.1 by bold outlined boxes on the left and right, respectively.

The DD architecture expects language specification to define mappings between interchanged and non-interchanged graphical information, but does not restrict how it is done. This is shown in Figure B.1 by a shaded box labeled "CS Mapping Specification" in the middle section. The DD specification gives examples of mappings in QVT, but does not define or recommend any particular mapping language. The overall architecture resembles typical model-view-controllers, which separate visual rendering from underlying models, and provide a way to keep visuals and models consistent.

The first few steps of using the DD architecture are:

1. An abstract language syntax is defined separately from DD by instantiating MOF (abstract syntaxes are sometimes called "metamodels"). This is shown in Figure B.1 by a shaded box labeled "AS" at the far middle left (the "M" levels in the figure are described in the UML 2 Infrastructure (formal/2009-02-04))

2. Language users model their applications by instantiating elements of abstract syntax, usually through tooling for the language. This is shown in Figure B.1 by the dashed arrow on the far lower left linked to a box labeled "Model."

3. Users typically see graphical depictions of their models in tools. This is shown in Figure B.1 by a box on the lower right labeled "Graphics."

Users expect their graphics to appear again in other tools after models are interchanged. The DD architecture enables this in two parts, one for graphical information that is interchanged, and another for graphical information that is not. The interchanged information is captured in the next few steps:
4. The portion of graphics that users have control over is captured for interchange, such as node position and line routing points. This is shown in Figure B.1 by a box labeled "Diagram" on the lower left. This information is linked to user models (instances of abstract syntax), as shown by the arrow to the Model box.

5. User diagram interchange information is instantiated from a model defined along with the abstract syntax. This is shown in Figure B.1 by a shaded box labeled "AS DI" on the left. Elements of this model are linked to elements of abstract syntax, specifying which kinds of diagram interchange information depict which kinds of user model elements. Diagram interchange models would typically be defined by the same community that defines the abstract syntax, as part of the overall language specification.

6. Elements of language-specific diagram interchange models (AS DI) specialize elements of the Diagram Interchange (DI), which is a model provided by this specification for typically needed diagram interchange information, as node position and line routing points. This is shown in Figure B.1 by the bold box labeled "DI" on the left, with specialization shown with a hollow headed arrow (specialization here is MOF generalization and property subsetting and redefinition, or XSD subclassing, where DI has the general elements, and AS DI has the specific elements). DI elements cannot be instantiated to capture diagram interchange information by themselves, they are almost entirely abstract. This specification provides normative CMOF and XSD artifacts for DI.

The final part of using the DD architecture captures graphical information that is not interchanged:

7. Language specifications specify mappings from their diagram interchange models (instances of AS DI) to instances of Diagram Graphics (DG), which is a model provided by this specification for typically needed graphical information that is not interchanged, such as shape and line styles. This is shown in Figure B.1 by the box labeled "DG" on the right, and by the box labeled "CS Mapping Specification" in the middle section. The arrow at the bottom of the middle section illustrates mappings being carried out according to the specification above it, producing a model of diagram visuals, or directly rendering the visuals on a display. Languages specifying this mapping reduce ambiguity and non uniformity in how their abstract syntax appears visually. The DG model is not expected to be specialized, enabling implementations to render instances of DG elements for all applications of the DD architecture. This specification provides normative CMOF and XSD artifacts for DG.

In the BPMN specification, the only realized part of the DD architecture so far is diagram interchange. Hence the only documentation provided by this annex is for the Diagram Interchange (DI) package, in addition to the relevant subset of Diagram Common (DC) package, which captures common data structure definitions. The documentation for the Diagram Graphics (DG) package is not provided here.
B.3 Diagram Common

The Diagram Common (DC) package contains abstractions shared by the Diagram Interchange and the Diagram Graphics packages.

B.3.1 Overview

The Diagram Common (DC) package contains a number of common primitive types as well as structured data types that are used in the definition of the Diagram Interchange (DG) package (section ?B.4). The DC package itself does not depend on other packages. Some of the types defined in this package are defined based on similar ones in other related specifications including Cascading Style Sheets (CSS), Scalable Vector Graphics (SVG) and Office Document Format (ODF).

B.3.2 Abstract Syntax

| «primitive» String | «primitive» Boolean | «primitive» Integer | «eDataType» Real |

Figure B.2 - The Primitive Types
B.3.3 Classifier Descriptions

Boolean [PrimitiveType]
Boolean is a primitive data type having one of two values: true or false, intended to represent the truth value of logical expressions.

Description
Boolean is used as a type for typed elements that represent logical expressions. There are only two possible values for Boolean:
- true - The Boolean expression is satisfied.
- false - The Boolean expression is not satisfied.

Abstract Syntax
- Figure B.2 The primitive types

Bounds [PrimitiveType]
Bounds specifies an area in some (x, y) coordinate system that is enclosed by a bounded element's top-left point, its width, and its height.

Description
Bounds is used to specify the area of an element in some (x, y) coordinate system. The area is specified with a top-left point, representing the element's location (distance from the origin in logical units of length), in addition to the element's width and height (in logical units of length).
Abstract Syntax

- Figure B.3 (Layout Types)

Attributes

- + x : Real [1] = 0
  a real number that represents the x-coordinate of the rectangle.
- + y : Real[1] = 0
  a real number that represents the y-coordinate of the rectangle.
- + width : Real [1]
  a real number that represents the width of the rectangle.
- + height : Real [1]
  a real number that represents the height of the rectangle.

**Font [PrimitiveType]**

Font specifies the characteristics of a given font through a set of font properties.

**Description**

Font specifies a set of properties for a given font that is used when rendering text on a diagram

Abstract Syntax

- Figure B.4 The font type

Attributes

- + name : String[0..1]
  the name of the font (e.g. "Times New Roman", "Arial" and "Helvetica").
- + size : Real [0..1]
  a non-negative real number representing the size of the font (expressed in the used unit of length).
- + isBold : Boolean [0..1]
  whether the font has a **bold** style.
- + isItalic : Boolean [0..1]
  whether the font has an *italic* style.
- + isUnderline : Boolean [0..1]
  whether the font has an underline style.
- + isStrikeThrough : Boolean [0..1]
  whether the font has a strike-through style.
**Integer [PrimitiveType]**

Integer is a primitive data type used to represent the mathematical concept of integer.

**Description**

Integer is used as a type for typed elements whose values are in the infinite set of integer numbers.

**Abstract Syntax**

- Figure B.2 The primitive types

**Point [DataType]**

A Point specifies an location in some (x, y) coordinate system.

**Description**

Point is used to specify a location in logical unit of length from the origin of some (x, y) coordinate system. The point (0, 0) is considered to be at the origin of that coordinate system.

**Abstract Syntax**

- Figure B.3 The layout types

**Attributes**

- + x : Real [1] = 0
  
  a real number that represents the x-coordinate of the point.

- + y : Real [1] = 0
  
  a real number that represents the y-coordinate of the point.

**Real [PrimitiveType]**

Real is a primitive data type used to represent the mathematical concept of real.

**Description**

Real is used as a type for typed elements whose values are in the infinite set of real numbers. Note that integer values (see ?B.3.3.4 Integer) are also considered real values and as such can be assigned to real-typed elements.

**Abstract Syntax**

- Figure B.2 The primitive types

**String [PrimitiveType]**

String is a primitive data type used to represent a sequence of characters in some suitable character set. Character sets may include both ASCII and Unicode characters.

**Description**

String is used as a type for typed elements in the metamodel that have text values. The allowed values for String depend on the semantics of the text in each context. A string value is a sequence of characters surrounded by double quotes (").
Abstract Syntax

- Figure B.2 The primitive types

B.4 Diagram Interchange

The Diagram Interchange (DI) package contains a model enabling interchange of graphical information that language users have control over, such as position of nodes and line routing points. Language specifications specialize elements of DI to define diagram interchange for a language.

B.4.1 Overview

The Diagram Interchange (DI) package contains a number of types used in the definition of diagram interchange models. The package imports the Diagram Common package (section ?B.3), as shown in Figure B.5, that contains various relevant data types. The DI package contains mainly abstract types that are to be properly extended and refined by concrete types in domain-specific DI packages. In this sense, the DI package plays the role of a framework that is meant for extension rather than a component that is ready to be used out of the box. The benefit of this design is capture common assumptions in the DI package in order to facilitate the integration between various graphical domains that define their DI packages as extensions.

Diagrams are generally considered depictions of part or all of the elements in a domain-specific model. Therefore, one of the best practices adopted in the design of the DI package and that can be subsumed by the extending domain-specific DI packages is to minimize any redundancy with the depicted model when possible. For example, the text representing the name of a UML class is not defined as part of the UML class shape. This is primarily achieved by the fact that diagram elements reference their counterparts in the domain model as their context model elements instead of duplicating data from them. This design has the side effect of coupling the diagram models with their corresponding domain models, which is generally a common practice by tools. However, the DI package does not enforce this best practice and domain-specific DI packages can decide to have some level of duplication to decouple the models.

Another best practice adopted by the DI package is to avoid defining any data that is not changeable by the user but is rather derivable from the diagram's model context, like graphical rendering details. For example, the option to render a UML actor as a stick man or a as rectangle can be defined in a DI model as a boolean property to allow a user to choose between them. However, the definition of the actual line segments making up such shapes need not be interchanged in a DI model as it can be defined in the tool itself.

Other decisions that are left to the individual domain-specific DI packages include: whether to allow 1-n vs. m-n relationships between the domain elements and their referencing diagram elements, the formatting properties (styles) that affect the aesthetics of diagrams rather than their semantics that are allowed to be interchanged, and the degree of pragmatic redundancy that is allowed in the DI models to balance their footprint with the ease of their import/export.

Figure B.10 - Plane

Figure B.11 - Labeled Edge
B.4.3 Classifier Descriptions

Diagram [Class]
Diagram is a container of a graph of diagram elements depicting all or part of a model.

Description
Diagram represents a depiction of all or part of a MOF model. A model can have one or more diagrams, each of which has a name and a description. A diagram contains the root of a graph of diagram elements that could reference various elements in a model. The root element is defined as a derived union, allowing domain-specific diagrams to specialize the root. All lengths specified by diagram elements are expressed in logical units of lengths. This unit of length would map to a unit of screen resolution (i.e., pixel) when rendering to the screen. To allow for predictable lengths when printing diagrams to paper, a diagram can also specify an intended printing resolution in Unit Per Inch (UPI). For example, a UPI of 300 means that a diagram element that is 300 unit wide would print as 1 inch wide on paper. A diagram can also own a collection of styles that are referenced by its diagram elements. Styles contain unique combination of formatting properties used by different elements across the diagram. This allows for a large number of diagram elements to reference a small number of unique styles, which would dramatically reduce a diagram's footprint.

Abstract Syntax
- Figure B.9 Diagram

Attributes
- + name : String [0..1]
the name of the diagram.

- + documentation : String [0..1]
  the documentation of the diagram.

- + resolution : Real [0..1]
  the printing resolution of the diagram expressed in Unit Per Inch (UPI).

Associations

  the root of containment for all diagram elements contained in the diagram.

- ? + /ownedStyle : Style [*] {readOnly, union}
  the collection of styles owned by the diagram and referenced by its contained diagram elements.

DiagramElement [Class]

DiagramElement is the abstract supertype of all elements that can be nested in a diagram. It has two subtypes: Node and Edge.

Description

DiagramElement specifies an element that can be owned by a diagram and rendered to graphics. It is an abstract class that is further specialized by classes Node and Edge. A diagram element can either depict (reference) another context model element from an abstract syntax model (like UML or BPMN) or be purely notational (i.e. for enhancing the diagram understanding). In the case of depiction, data from both the diagram element and the model element are used for rendering. For example, the text of the name label of a UML class shape comes from the class, while the color of the label comes from the diagram element. A diagram element can reference a maximum of one model element, which can be any MOF-based element. The model element reference is a derived union and can be specialized in a domain-specific DI metamodel to be of a more concrete type.

Diagram elements can also own other diagram elements in a graph-like hierarchy. The collection of owned diagram elements is defined as a derived union. Domain-specific DI metamodels can specialize this collections to define what other diagram elements can be nested in a given diagram element.

Diagram elements can be specialized in a domain-specific DI metamodel to have domain-specific properties. Some of those properties augment the semantics of diagram elements and are therefore defined on the diagram elements. Other properties are considered formatting properties that influence the visual rendering of diagram elements but do not contribute to their semantics. Examples of such formatting properties include font, fill and stroke properties. Such properties tend to have similar values for diagram elements across the diagram and therefore to reduce the footprint of diagrams, they are defined in Style elements that are owned by the diagram and referenced by individual diagram elements. For every unique combination of values for the style properties there would be a separate style element that is owned by the diagram. See section ?B.4.3.10 for more details.

There shall always be other properties that some tools wish to interchange that cannot be made normative. These can be interchanged using the extensibility mechanism that is native to the used interchange format (for example, an XSD schema following the XMI mapping would allow extraneous data to be placed on elements within <xmi:extension> tags, while a different XSD schema could allow this through xsd:any and xsd:anyAttribute elements placed in the definitions of extensible complex types).

Abstract Syntax

- Figure B.6 Diagram Element
• Figure B.7 Node
• Figure B.8 Edge
• Figure B.9 Diagram
• Figure B.10 Plane

Specializations

• Node
• Edge

Associations

• + /owningDiagram : Diagram [0..1] {readOnly, union}
  a reference to the diagram that directly owns this diagram element. The reference is only set for the root element in a diagram.
• + /owningElement : DiagramElement [0..1] {readOnly, union}
  a reference to the diagram element that directly owns this diagram element. The reference is set for all elements except the root element in a diagram.
• ? + /ownedElement : DiagramElement [*] {readOnly, union}
  a collection of diagram elements that are owned by this diagram element.
• + /modelElement : Element [0..1] {readOnly, union}
  a reference to a context model element, which can be any MOF-based element, for the diagram element.
• + /style : Style [0..1] {readOnly, union}
  a reference to an optional style containing formatting properties for the diagram element.

Edge [Class]

Edge specifies a given edge in a graph of diagram elements. It represents a polyline connection between two graph elements: a source and a target.

Description

Edge represents a given connection between two elements in a diagram, a source element and a target element. An edge often references a relationship element (like a UML generalization or a BPMN message flow) as a context model element. It can also be purely notational, i.e. does not reference any model element. When referencing a relationship model element, the edge's source and target reference the relationship's source and target respectively as their model elements. If the edge's source and target can be derived unambiguously from other info (like the edge's model element or the edge's class type), they are not explicitly set on the edge to avoid redundancy, otherwise they need to be set. The source and target are defined as derived unions to allow domain-specific DI metamodels to specialize them appropriately.

An edge is often depicted as a line with 2 or more points (i.e. one or more connected line segments) in the coordinate system, called waypoints. The first point typically intersects with the edge's source, while the last point typically intersects with the edge's target. Any points in between establish a route for the line to traverse in the diagram.
Abstract Syntax

- Figure B.8 Edge
- Figure B.11 Labeled Edge

Generalizations

- DiagramElement

Specializations

- LabeledEdge

Attributes

- + waypoint : Point [2..*] \{ordered, nonunique\}
  
a list of two or more points relative to the origin of the coordinate system (e.g. the origin of a containing plane) that
  specifies the connected line segments of the edge.

Associations

- + /source : DiagramElement [0..1] \{readOnly, union\}
  
  the edge's source diagram element, i.e. where the edge starts from. It is optional and needs to be set only if it cannot be
  unambiguously derived.

- + /target : DiagramElement [0..1] \{readOnly, union\}
  
  the edge's target diagram element, i.e. where the edge ends at. It is optional and needs to be set only if it cannot be
  unambiguously derived.

**Label [Class]**

Label represents a node that is owned by another main diagram element in a plane and that depicts some (usually textual)
aspect of that element within its own separate bounds.

Description

Label represents an owned node of another diagram element, typically a LabeledShape or a LabeledEdge. A label typically
depicts some (usually textual) aspect of its owning element that needs to be laid out separately using the label's own bounds.
The bounds are optional and if not specified, the label will be positioned in its default position.

A label's model element is typically not specified as it can be derived from its owning element. However, if the model element
cannot be unambiguously derived, then a label could be given its own separate model element to disambiguate it.

Abstract Syntax

- Figure B.11 (Labeled Edge)
- Figure B.12 Labeled Shape

Generalizations

- Node

Attributes

- + bounds : Bounds [1]
the bounds (x, y, width and height) of the label relative to the origin of a containing plane.

**LabeledEdge [Class]**

LabeledEdge represents an edge that owns a collection of labels.

**Description**

LabeledEdge is an edge that owns a collection of labels (section ?B.4.3.4) that depict some aspects of it. An example is a UML association that has a number of labels (e.g. a name label, two role name labels and two multiplicity labels) positioned beside it. The existence of a label in this collection specifies that it is visible. The separate optional bounds of the label indicate where it should be positioned and if not specified the label can be positioned in its default position.

**Abstract Syntax**

- Figure B.11 Labeled Edge

**Generalizations**

- Edge

**Associations**

- ? + /ownedLabel : Label [*] {readOnly, union, subsets ownedNode}
  the collection of labels owned by this edge.

**LabeledShape [Class]**

LabeledShape represents a shape that owns a collection of labels.

**Description**

LabeledShape is a shape that owns a collection of labels (section B.4.3.4) that depict some aspects of it. An example is a UML port shape that is rendered as a filled box and has a name label positioned beside it. The existence of a label in this collection specifies that it is visible. The separate optional bounds of the label indicate where it should be positioned and if not specified the label can be positioned in its default position.

**Abstract Syntax**

- Figure B.12 Labeled Shape

**Generalizations**

- Shape

**Associations**

- ? + /ownedLabel : Label [*] {readOnly, union, subsets ownedNode}
  the collection of labels owned by this shape.

**Node [Class]**

Node specifies a given node in a graph of diagram elements.

**Description**

Node represents a given node (or vertex) in a diagram, which is a graph of diagram elements. A node often references a non-relationship element (like a UML class or a BPMN activity) as a model element. It can also be purely notational, i.e. does not reference any model element.
The abstract node class does not have any particular layout characteristics. However, it may get specialized in a domain-specific DI metamodel to define nodes that have certain layout characteristics. Examples include planes with infinite bounds, shapes with limited bounds, tree items and graph vertices...etc.

Abstract Syntax

- Figure B.11 Labeled Edge
- Figure B.12 Labeled Shape
- Figure B.13 Shape

Generalizations

- DiagramElement

Specializations

- Label
- Shape
- Plane

Plane [Class]

Plane is a node with an infinite bounds in the x-y coordinate system that owns a collection of shapes and edges that are laid out relative to its origin point.

Description

Plane has an origin point (0, 0) and an infinite size along the x and y axes. The coordinate system of the plane increases along the x-axis from left to right and along the y-axis from top to bottom. All the nested shapes and edges are laid out relative to their plane's origin.

A plane is often chosen as a root element for a two dimensional diagram that depicts an inter-connected graph of shapes and edges. A plane may have its own reference to a model element, in which case the whole plane is considered a depiction of that element. Alternatively, a plane without a reference to a model element is simply a layout container for its shapes and edges.

The collection of plane elements (shapes and edges) in a plane is ordered with the order specifying the z-order of these plane elements relative to each other. The higher the z-order, the more to the front (on top) the plane element is.

Abstract Syntax

- Figure B.10 Plane

Generalizations

- Node

Associations

- ? + planeElement : DiagramElement [*] {subsets ownedNode}
  
  the ordered collection of diagram elements owned by this plane with the order defining the z-order of the diagram element.
Shape [Class]
Shape represents a node that has bounds that is relevant to the origin of a containing plane.

Description
Shape represents a node that is directly or indirectly owned by a plane (section ?B.4.3.8) and that is laid out according to a given bounds that is relevant to the origin of the plane. A shape does not have any particular graphical rendering, i.e. the rendering is domain-specific.

A shape can be purely notational (i.e. does not reference any model element), like a block arrow pointing to a UML class shape with some textual message or an overlay rectangle with some transparent fill enclosing a bunch of shapes on the diagram to make them stand out. However, a shape often represents a depiction of a non-relational element from a business model (like UML class or BPMN activity) and hence references such an element as its model element.

Abstract Syntax
- Figure B.13 Shape
- Figure B.12 Labeled Shape

Generalizations
- Node

Specializations
- LabeledShape

Attributes
- + bounds : Bounds [1]
  the bounds (x, y, width and height) of the shape relative to the origin of a containing plane.

Style [Class]
A style is a container for a collection of properties that affect the formatting of a set of diagram elements rather than their structure or semantics.

Description
A style represents a bag of properties that affect the appearance of a group of diagram elements. A style property (like font, fill or stroke) is distinguishable from a property on a diagram element in that it is meant for the aesthetics of the element rather than being part of its intrinsic syntax.

A style tends to have only a few unique value combinations for its properties across the diagram. Such combinations are represented by different style instances owned by the diagram and referenced by the diagram elements. This allows for conserving the footprint of diagrams (over making style instances owned by diagram elements).

Style is defined as an abstract class without prescribing any style properties to leave it up to domain-specific DI metamodels to define concrete style classes that are applicable to their diagram element types.

# Annex C: Glossary

*(informative)*

## A

**Activity**
Work that a company or organization performs using business processes. An activity can be atomic or non-atomic (compound). The types of activities that are a part of a Process Model are: Process, Sub-Process, and Task.

**Abstract Process**
A Process that represents the interactions between a private business process and another process or participant.

**Artifact**
A graphical object that provides supporting information about the Process or elements within the Process. However, it does not directly affect the flow of the Process.

**Association**
A connecting object that is used to link information and Artifacts with Flow Objects. An association is represented as a dotted graphical line with an arrowhead to represent the direction of flow.

**Atomic Activity**
An activity not broken down to a finer level of Process Model detail. It is a leaf in the tree-structure hierarchy of Process activities. Graphically it will appear as a Task in BPMN.

## B

**Business Analyst**
A specialist who analyzes business needs and problems, consults with users and stakeholders to identify opportunities for improving business return through information technology, and defines, manages, and monitors the requirements into business processes.

**Business Process**
A defined set of business activities that represent the steps required to achieve a business objective. It includes the flow and use of information and resources.

**Business Process Management**
The services and tools that support process management (for example, process analysis, definition, processing, monitoring and administration), including support for human and application-level interaction. BPM tools can eliminate manual processes and automate the routing of requests between departments and applications.

**BPM System**
The technology that enables BPM.

## C

**Choreography**
An ordered sequence of B2B message exchanges between two or more Participants. In a Choreography there is no central controller, responsible entity, or observer of the Process.
| **Collaboration** | Collaboration is the act of sending messages between any two Participants in a BPMN model. The two Participants represent two separate BPML processes. |
| **Collapsed Sub-Process** | A Sub-Process that hides its flow details. The Collapsed Sub-Process object uses a marker to distinguish it as a Sub-Process, rather than a Task. The marker is a small square with a plus sign (+) inside. |
| **Compensation Flow** | Flow that defines the set of activities that are performed while the transaction is being rolled back to compensate for activities that were performed during the Normal Flow of the Process. A Compensation Flow can also be called from a Compensate End or Intermediate Event. |
| **Compound Activity** | An activity that has detail that is defined as a flow of other activities. It is a branch (or trunk) in the tree-structure hierarchy of Process activities. Graphically, it will appear as a Process or Sub-Process in BPMN. |
| **Controlled Flow** | Flow that proceeds from one Flow Object to another, via a Sequence Flow link, but is subject to either conditions or dependencies from other flow as defined by a Gateway. Typically, this is seen as a Sequence flow between two activities, with a conditional indicator (mini-diamond) or a Sequence Flow connected to a Gateway. |
| **Decision** | A gateway within a business process where the Sequence Flow can take one of several alternative paths. Also known as "Or-Split." |
| **End Event** | An Event that indicates where a path in the process will end. In terms of Sequence Flows, the End Event ends the flow of the Process, and thus, will not have any outgoing Sequence Flows. An End Event can have a specific Result that will appear as a marker within the center of the End Event shape. End Event Results are Message, Error, Compensation, Signal, Link, and Multiple. The End Event shares the same basic shape of the Start Event and Intermediate Event, a circle, but is drawn with a thick single line. |
| **Event Context** | An Event Context is the set of activities that can be interrupted by an exception (Intermediate Event). This can be one activity or a group of activities in an expanded Sub-Process. |
| **Exception** | An event that occurs during the performance of the Process that causes a diversion from the Normal Flow of the Process. Exceptions can be generated by Intermediate Events, such as time, error, or message. |
| **Exception Flow** | A Sequence Flow path that originates from an Intermediate Event attached to the boundary of an activity. The Process does not traverse this path unless the Activity is interrupted by the triggering of a boundary Intermediate Event (an Exception - see above). |
| **Expanded Sub-Process** | A Sub-Process that exposes its flow detail within the context of its Parent Process. An Expanded Sub-Process is displayed as a rounded rectangle that is enlarged to display the Flow Objects within. |
| **Flow** | A directional connector between elements in a Process, Collaboration, or Choreography. A Sequence Flow represents the sequence of Flow Objects in a Process or Choreography. A Message Flow represents the transmission of a Message between Collaboration Participants. The term Flow is often used to represent the overall progression of how a Process or Process segment would be performed. |
| **Flow Object** | A graphical object that can be connected to or from a Sequence Flow. In a Process, Flow Objects are Events, Activities, and Gateways. In a Choreography, Flow Objects are Events, Choreography Activities, and Gateways. |
| **Fork** | A point in the Process where one Sequence Flow path is split into two or more paths that are run in parallel within the Process, allowing multiple activities to run simultaneously rather than sequentially. BPMN uses multiple outgoing Sequence Flows from Activities or Events or a Parallel Gateway to perform a Fork. Also known as "AND-Split." |
| **Intermediate Event** | An event that occurs after a Process has been started. An Intermediate Event affects the flow of the process by showing where messages and delays are expected, distributing the Normal Flow through exception handling, or showing the extra flow required for compensation. However, an Intermediate Event does not start or directly terminate a process. An Intermediate Event is displayed as a circle, drawn with a thin double line. |
| **Join** | A point in the Process where two or more parallel Sequence Flow paths are combined into one Sequence Flow path. BPMN uses a Parallel Gateway to perform a Join. Also known as "AND-Join." |
| **Lane** | A partition that is used to organize and categorize activities within a Pool. A Lane extends the entire length of the Pool either vertically or horizontally. Lanes are often used for such things as internal roles (e.g., Manager, Associate), systems (e.g., an enterprise application), or an internal department (e.g., shipping, finance). |
| **Merge** | A point in the Process where two or more alternative Sequence Flow paths are combined into one Sequence Flow path. No synchronization is required because no parallel activity runs at the join point. BPMN uses multiple incoming Sequence Flows for an Activity or an Exclusive Gateway to perform a Merge. Also known as "OR-Join." |
| **Message** | An Object that depicts the contents of a communication between two Participants. A message is transmitted through a Message Flow and has an identity that can be used for alternative branching of a Process through the Event-Based Exclusive Gateway. |
| **Message Flow** | A Connecting Object that shows the flow of messages between two Participants. A Message Flow is represented by a dashed lined. |
| **Normal Flow** | A flow that originates from a Start Event and continues through activities on alternative and parallel paths until reaching an End Event. |
| **P** |  |
| **Parent Process** | A Process that holds a Sub-Process within its boundaries. |
| **Participant** | A business entity (e.g., a company, company division, or a customer) or a business role (e.g., a buyer or a seller) that controls or is responsible for a business process. If Pools are used, then a Participant would be associated with one Pool. In a Collaboration, Participants are informally known as "Pools.". |
| **Pool** | A Pool represents a Participant in a Collaboration. Graphically, a Pool is a container for partitioning a Process from other Pools/Participants. A Pool is not required to contain a Process, i.e., it can be a "black box." |
| **Private Business Process** | A process that is internal to a specific organization and is the type of process that has been generally called a workflow or BPM process. |
| **Process** | A sequence or flow of Activities in an organization with the objective of carrying out work. In BPMN, a Process is depicted as a graph of Flow Elements, which are a set of Activities, Events, Gateways, and Sequence Flow that adhere to a finite execution semantics. |
| **R** |  |
| **Result** | The consequence of reaching an End Event. Types of Results include Message, Error, Compensation, Signal, Link, and Multiple. |
| **S** |  |
| **Sequence Flow** | A connecting object that shows the order in which activities are performed in a Process and is represented with a solid graphical line. Each Flow has only one source and only one target. A Sequence Flow can cross the boundaries between Lanes of a Pool but cannot cross the boundaries of a Pool. |
| **Start Event** | An Event that indicates where a particular Process starts. The Start Event starts the flow of the Process and does not have any incoming Sequence Flow, but can have a Trigger. The Start Event is displayed as a circle, drawn with a single thin line. |
| **Sub-Process** | A Process that is included within another Process. The Sub-Process can be in a collapsed view that hides its details. A Sub-Process can be in an expanded view that shows its details within the view of the Process that it is contained in. A Sub-Process shares the same shape as the Task, which is a rectangle that has rounded corners. |
| **Swimlane** | A Swimlane is a graphical container for partitioning a set of activities from other activities. BPMN has two different types of Swimlanes. See “Pool” and “Lane.” |
| **T** |  |
| **Task** | An atomic activity that is included within a Process. A Task is used when the work in the Process is not broken down to a finer level of Process Model detail. Generally, an end-user, an application, or both will perform the Task. A Task object shares the same shape as the Sub-Process, which is a rectangle that has rounded corners. |
| **Token** | A theoretical concept that is used as an aid to define the behavior of a Process that is being performed. The behavior of Process elements can be defined by describing how they interact with a token as it "traverses" the structure of the Process. For example, a token will pass through an Exclusive Gateway, but continue down only one of the Gateway's outgoing Sequence Flow. |
| **Transaction** | A Sub-Process that represents a set of coordinated activities carried out by independent, loosely-coupled systems in accordance with a contractually defined business relationship. This coordination leads to an agreed, consistent, and verifiable outcome across all participants. |
| **Trigger** | A mechanism that detects an occurrence and can cause additional processing in response, such as the start of a business Process. Triggers are associated with Start Events and Intermediate Events and can be of the type: Message, Timer, Conditional, Signal, Link, and Multiple. |
| **Uncontrolled Flow** | Flow that proceeds without dependencies or conditional expressions. Typically, an Uncontrolled Flow is a Sequence Flow between two Activities that do not have a conditional indicator (mini-diamond) or an intervening Gateway. |
