---

This OMG document replaces the earlier document (ptc/2015-05-01, Beta 1). This is an OMG Adopted Beta Specification and is currently in the finalization phase. Comments on the content of this document are welcome, and should be directed to [issues@omg.org](mailto:issues@omg.org) by August 24, 2015.

You may view pending issues for this specification from the OMG revision issues web page <http://www.omg.org/issues>.

The FTF Recommendation and Report for this specification will be published on December 18, 2015. If you are reading this after that date, please download the available specification

from the OMG Specifications web page <http://www.omg.org/spec/>.

#### USE OF SPECIFICATION - TERMS, CONDITIONS & NOTICES

The material in this document details an Object Management Group specification in accordance with the terms, conditions and notices set forth below. This document does not represent a commitment to implement any portion of this specification in any company's products. The information contained in this document is subject to change without notice.

#### LICENSES

The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

Subject to all of the terms and conditions below, the owners of the copyright in this specification hereby grant you a fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use this specification to create and distribute software and special purpose specifications that are based upon this specification, and to use, copy, and distribute this specification as provided under the Copyright Act; provided that: (1) both the copyright notice identified above and this permission notice appear on any copies of this specification; (2) the use of the specifications is for informational purposes and will not be copied or posted on any network computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3) no modifications are made to this specification. This limited permission automatically terminates without notice if you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the specifications in your possession or control.

## PATENTS

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.

## GENERAL USE RESTRICTIONS

Any unauthorized use of this specification may violate copyright laws, trademark laws, and communications regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved. No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic, electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems--without permission of the copyright owner.

## DISCLAIMER OF WARRANTY

WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE OR USE. IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The entire risk as to the quality and performance of software developed using this specification is borne by you. This disclaimer of warranty constitutes an essential part of the license granted to you to use this specification.

## RESTRICTED RIGHTS LEGEND

Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1) (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)(1) and (2) of the Commercial Computer

Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as indicated above and may be contacted through the Object Management Group, 109 Highland Ave, Needham, MA 02494 USA

## TRADEMARKS

MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are registered trademarks of the Object Management Group, Inc., and Object Management Group™, OMG™, Unified Modeling Language™, Model Driven Architecture Logo™, Model Driven Architecture Diagram™, CORBA logos™, XMI Logo™, CWM™, CWM Logo™, IIOP™, IMM™, MOF™, OMG Interface Definition Language (IDL)™, and OMG SysML™ are trademarks of the Object Management Group. All other products or company names mentioned are used for identification purposes only, and may be trademarks of their respective owners.

## COMPLIANCE

The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer software to use certification marks, trademarks or other special designations to indicate compliance with these materials.

Software developed under the terms of this license may claim compliance or conformance with this specification if and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this specification, but may not claim compliance or conformance with this specification. In the event that testing suites are implemented or approved by Object Management Group, Inc., software developed using this specification may claim compliance or conformance with the specification only if the software satisfactorily completes the testing suites.

## **OMG's Issue Reporting Procedure**

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page <http://www.omg.org>, under Documents, Report a Bug/Issue ([http://www.omg.org/report\\_issue.htm](http://www.omg.org/report_issue.htm))

## Preface

### OMG

Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer industry standards consortium that produces and maintains computer industry specifications for interoperable, portable, and reusable enterprise applications in distributed, heterogeneous environments. Membership includes Information Technology vendors, end users, government agencies, and academia.

OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle approach to enterprise integration that covers multiple operating systems, programming languages, middleware and networking infrastructures, and software development environments. OMG's specifications include: UML® (Unified Modeling Language™); CORBA® (Common Object Request Broker Architecture); CWM™ (Common Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

More information on the OMG is available at <http://www.omg.org/>.

### OMG Specifications

As noted, OMG specifications address middleware, modeling and vertical domain frameworks. All OMG Specifications are available from the OMG website at:

<http://www.omg.org/spec>

Specifications are organized by the following categories:

- Business Modeling Specifications
- Middleware Specifications
  - CORBA/IIOP
  - Data Distribution Services
  - Specialized CORBA
- IDL/Language Mapping Specifications
- Modeling and Metadata Specifications
  - UML, MOF, CWM, XMI
  - UML Profile
- Modernization Specifications
- Platform Independent Model (PIM), Platform Specific Model (PSM), Interface Specifications
  - CORBAServices
  - CORBAFacilities

- OMG Domain Specifications
  - CORBA Embedded Intelligence Specifications
  - CORBA Security Specifications

All of OMG's formal specifications may be downloaded without charge from our website. (Products implementing OMG specifications are available from individual suppliers.) Copies of specifications, available in PostScript and PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management Group, Inc. at:

Object Management Group  
109 Highland Ave  
Needham, MA 02494 USA

Tel: +1-781-444-0404  
Fax: +1-781-444-0320  
Email: [pubs@omg.org](mailto:pubs@omg.org)

Certain OMG specifications are also available as ISO standards. Please consult <http://www.iso.org>

### Typographical Conventions

The type styles shown below are used in this document to distinguish programming statements from ordinary English. However, these conventions are not used in tables or sub clause headings where no distinction is necessary.

Times/Times New Roman - 10 pt.: Standard body text

**Helvetica/Arial - 10 pt. Bold:** OMG Interface Definition Language (OMG IDL) and syntax elements.

**Courier - 10 pt. Bold:** Programming language elements.

Helvetica/Arial - 10 pt: Exceptions

NOTE: Terms that appear in italics are defined in the glossary. Italic text also represents the name of a document, specification, or other publication.

**Issues** The reader is encouraged to report any technical or editing issues/problems with this specification to [http://www.omg.org/report\\_issue.htm](http://www.omg.org/report_issue.htm).

# 1 Scope

The Data Distribution Service is widely used for data-centric publish/subscribe communication in real-time distributed systems. Large distributed systems often need more than one style of communication. For instance, data distribution works great for one-to-many dissemination of information. However, certain other styles of communication namely request/reply and remote method invocation are cumbersome to express using the basic building blocks of DDS. Using two or more middleware frameworks is often not practical due to complexity, cost, and maintenance overhead reasons. As a consequence, developing a standard mechanism for request/reply style bidirectional communication on top of DDS is highly desirable for portability and interoperability. Such facility would allow commands to be naturally represented as remote method invocations. This s presents a solution to this problem.

This specification defines a Remote Procedure Calls (RPC) framework using the basic building blocks of DDS, such as topics, types, DataReaders, and DataWriters to provide request/reply semantics. It defines distributed services, described using a service interface, which serves as a shareable contract between service provider and a service consumer. It supports synchronous and asynchronous method invocation. Despite its similarity, it is not intended to be a replacement for CORBA.

# 2 Conformance

This specification defines two conformance points: Basic and Enhanced.

[1] Basic conformance (mandatory).

[2] Enhanced conformance (optional).

The basic conformance point includes support for the Basic service mapping and both the functional and the request-reply language binding styles.

The enhanced conformance point includes the basic conformance and adds support for the Enhanced Service mapping.

The table below summarizes what is included in each of the conformance points.

Conformance point	Service Mapping		Language Binding Style	
	Basic	Enhanced	Function-call	Request/Reply
Basic	Included		Included	Included
Enhanced	Included	Included	Included	Included

# 3 Normative References

The following normative documents contain provisions which, through reference in this text, constitute provisions of this specification. For dated references, subsequent amendments to, or

revisions of, any of these publications do not apply.

## 4 Terms and Definitions

For the purposes of this specification, the following terms and definitions apply.

### Service

A Service is a mechanism to enable access to one or more capabilities, where the access is provided using a prescribed interface and is exercised consistent with constraints and policies as specified by the service description. (~~Source: OASIS SOA Reference Model~~)[SOA-RM]

## **Remote Procedure Call**

Remote Procedure Call is an inter-process communication that allows a computer program to cause a subroutine or procedure to execute in another address space

## **5 Symbols**

DDS	Data-Distribution Service
GUID	Global Unique Identifier
RPC	Remote Procedure Call
RTPS	Real-Time Publish-Subscribe Protocol
SN	Sequence Number

## **6 Additional Information**

### **6.1 Changes to Adopted OMG Specifications**

None

### **6.2 Acknowledgements**

The following companies submitted this specification:

- Real-Time Innovations, Inc.
- eProxima
- PrismTech

The following companies support this specification:

- Real-Time Innovations, Inc.
- eProxima
- PrismTech
- Twin Oaks Computing, Inc.

## 7 Remote Procedure Call over Data Distribution Service

### 7.1 Overview

[\[Issue DDSRPC -7: Editorial corrections in the spec document\]](#) Large distributed systems often require different [communicationinteraction](#) patterns depending upon the problem at hand. For instance, distribution of sensor data is best achieved using unidirectional *one-to-many* pattern whereas sending commands to a specific device or retrieving configuration of a remote service is best done using bidirectional request/reply [communicationinteraction](#). Using a single middleware that supports multiple [communicationinteraction](#) styles is a very cost-effective way of developing and maintaining large distributed systems. Data Distribution Service (DDS) is a well-known standard for data-centric publish-subscribe [communicationinteraction](#) for real-time distributed systems. DDS excels at providing an abstraction of global data space where applications can publish real-world data and also subscribe to it without temporal or spatial coupling.

DDS, however, is cumbersome to use for bidirectional [communicationinteraction](#) in the sense of request-reply pattern. The pattern can be expressed using the basic building blocks of DDS, however, substantial plumbing must be created manually to achieve the desired effect. As a consequence, it is fair to say that request/reply style [communicationinteraction](#) is not *first-class* in DDS. The intent of this submission is to specify higher-level abstractions built on top of DDS to achieve *first-class* request/reply [communicationinteraction](#). It is also the intent of this submission to facilitate portability, interoperability, and promote data-centric view for request/reply [communicationinteraction](#) so that the architectural benefits of using DDS can be leveraged in request/reply [communicationinteraction](#).

### 7.2 General Concepts

#### 7.2.1 Architecture

Remote Procedure Call necessarily has two participants: a *client* and a *service*. Structurally, every client uses a data writer for sending requests and a data reader for receiving replies. Symmetrically, every *service* uses a data reader for receiving the requests and a data writer for sending the replies.

Figure 1 shows the high-level architecture of the remote procedure call over DDS. The client consists of a data writer to publish the sample that represents remote procedure call on the *call* topic.

Correspondingly, the service implementation contains a data reader [that receives the request containing the method name and the parameters \(e.g., Foo\) to read the method name and the parameters \(i.e., Foo\)](#). The service computes the return values (i.e., Bar) to be sent back to the client on the *Return* topic. (The service implementation details are not shown.)

The data reader at the client side receives the response, which is delivered to the application. To ensure that the client receives a response to a previous call made by itself, a content-based filter [is-could be](#) used by the reader at the client-side. This ensures that responses for remote invocations of other clients are filtered [out](#).

It is possible for a client to have more than one outstanding request, particularly when asynchronous invocations are used. In such cases, it is critical to correlate requests with responses. As a consequence, each individual request must be correlated with the corresponding reply. Requests, like

all samples in the DDS data space, are identified using a unique `SampleIdentity` defined as a struct composed of `GUID_t` and a `SequenceNumber_t` defined in sub clause 7.5.1.1.1. When a service implementation sends a reply to a specific remote invocation, it is necessary to identify the original request by providing the *sample identity request-id* of the request. Note that a reply data sample has its own unique *message-id* (sample identity), which represents the reply message itself and is independent of the request-*id-sample identity*.

Formatted: Font: Italic

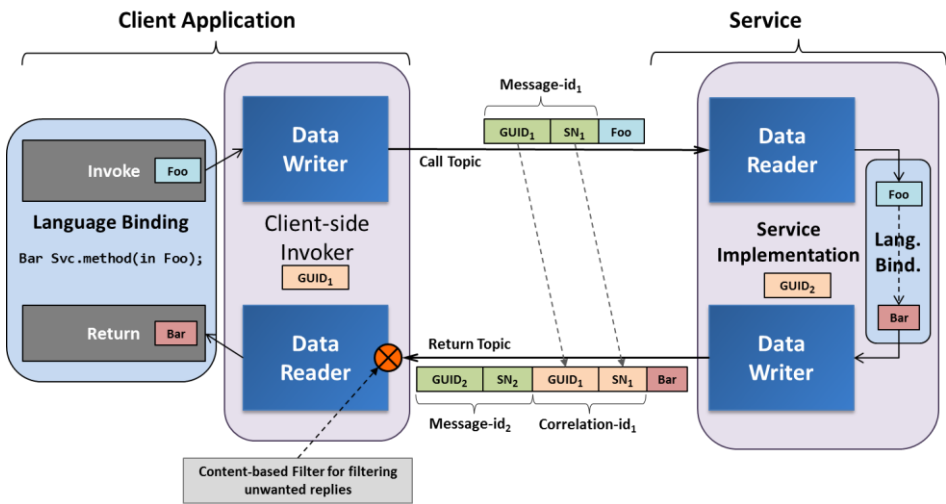

Figure 1: Conceptual View of Remote Procedure Call over DDS

## 7.2.2 Language Binding Styles for RPC over DDS

Language binding style determines how the client API is exposed to the programmer and how the service implementation receives notification of the arriving requests. This specification includes a higher-level language binding with *function-call* style and a lower-level language binding with *request/reply* style.

### 7.2.2.1 Function-call Style

Issue DDSRPC -1: Clarifications and simple technical corrections

The function-call style is conceptually analogous to Java RMI, .NET WFC Service Contracts, or CORBA. To provide function-call style, a common approach is to generate *stubs* that serve as client-side proxies for remote operations and *skeletons* to support service-side implementations. The look-and-feel is like a local function invocation. A code generator generates *stub* and *skeleton* classes from an interface specification. The generated code is used by the client and service implementation. An advantage of such a mapping is that the look and feel of the client-side program and the service

Formatted: Highlight

Formatted: Highlight

Formatted: Highlight

implementation is just like a native method call. Asynchronous invocations use `dds::rpc::future<T>` to retrieve the result of the operation.

Formatted: Font: (Default) Courier New, 10 pt

### 7.2.2.2 Request/Reply Style

The request/reply style makes no effort to make the remote invocation look like a function call. Instead, it provides a general-purpose API to send and receive messages. The programmer is responsible for populating the request messages (a.k.a. samples) at the client side and the reply messages on the service side. In that sense it is lower-level language binding compared to the function-call semantics.

The request/reply style provides a flat interface, such as `send_request`, `receive_request`, and `send_reply`, `receive_reply`, which substantially simplifies language binding as no code generation is necessary beyond the request/reply types. However, remote procedure call does not appear *first-class* to the programmer.

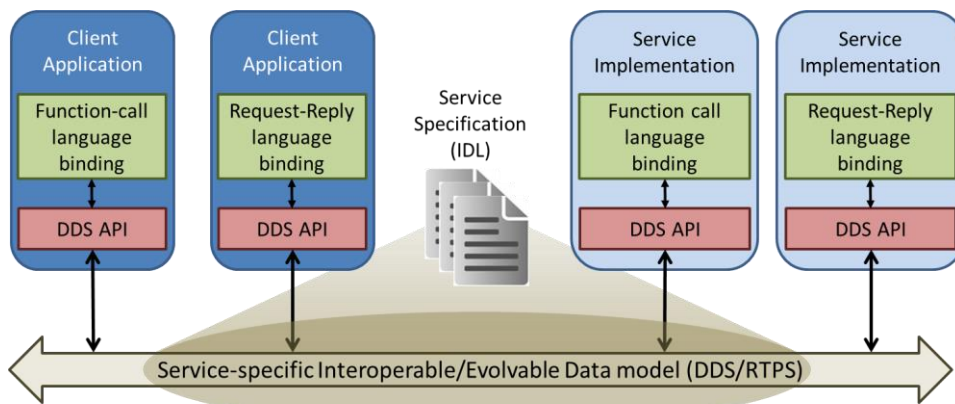

Figure 2: Strong decoupling of language binding (function-call and request/reply) from the service-specific data model

### 7.2.2.3 Pros and Cons of each Language Binding Styles

The function-call style is natural to programmers due to its familiar look-and-feel. Sending of the request message and reception of the corresponding reply is abstracted away using *proxy* objects on the client side. Request-reply style, on the other hand, is more explicit about exchanging messages and therefore can be used to implement complex interactions between the client and the server. For example, the *command-response* pattern typically involves multiple replies to the same request. (e.g., completion percentage status). Request-reply style can easily implement such a pattern without polling. For a given request, a service may simply produce multiple replies with the same request-id as that of the original request. The client correlates the replies with the original request using the request-id. The function-call style must use application-level polling or asynchronous callbacks if

multiple replies are expected by the client. This is because the *single-entry-single-return* semantics restrict underlying messaging.

Furthermore, request-reply style is inherently asynchronous because invocation of the service is separated from reception of replies. Multiple replies (for a single request) may be consumed one at a time or in a batch. The API for request-reply style often simplifies code-generation requirements because stubs and skeletons are not required. Finally, the request-reply style is strongly typed and this specification uses templates in case of C++ and generics in case of Java to provide service-specific type-rich language bindings.

It is important to note that the client and service sides are not coupled with respect to the language binding styles. Thanks to the strong separation imposed by the mapping of interfaces to topic types. It is possible for a client to use function-call style language binding to invoke remote operations on a server that uses request/reply style language binding to implement the service. The converse is also true. Furthermore, it is also possible for the stubs and skeletons of the functional style to use the request/reply language binding under the hood.

In light of the above observation, a conforming implementation to this specification shall support both styles of language binding.

### 7.2.3 Request-Reply Correlation

Request-reply correlation requires an ability to retrieve the sample identity (GUID, SN) at both the requester and service side. The requester needs to know the sample identity because it needs to correlate the reply with the original request. The service implementation also needs to retrieve the sample identity of the request so that it can use it to relate the reply sample to the request that triggered it.

This specification makes important distinction in how the information necessary for correlation is propagated. The ~~sample identity request-id~~ can be propagated either *implicitly* or *explicitly*. Explicit ~~sample identity request-id~~ implies that the request-id is visible in the top-level data type for the DDS topic. Implicit ~~sample identity request-id~~, on the other hand, implies that the request-~~d sample identity~~ is communicated via extensibility mechanisms supported by the DDS-RTPS protocol. Specifically using the *inlineQoS* sub-message element. See sub clause 8.3.7.2 of the DDS-RTPS specification [RTPS].

[\[Issue DDSRPC -1: Clarifications and simple technical corrections\]](#)

In both cases, the specification provides APIs to get the request-id at the client side and get/set the request-id at the service side. The request-id simply maps to `dds::SampleIdentity` structure that contains `GUID_t` and `SequenceNumber_t` both of which are predefined in [RTPS]. The API to retrieve request-id is included in the accompanying normative machine readable files.

Formatted: Font: (Default) Courier New, 10 pt

Formatted: Font: (Default) Courier New, 10 pt

### 7.2.4 Basic and Enhanced Service Mapping for RPC over DDS

This specification includes two mappings for interfaces to DDS topics and types called “Basic” and “Enhanced”.

- The Basic service mapping enables RPC over DDS functionality without any extensions to the [DDS] and [DDS-RTPS] specifications. It uses explicit request-id for correlation

- The Enhanced service mapping uses implicit request-id for correlation, allows use of the additional data-types defined in DDS-XTypes, uses DDS-XTypes for type-compatibility checking, and provides more robust service discovery.

The following table summarizes the key aspects of the Basic and Enhanced service mapping profiles

Mapping Aspect	Basic Service Mapping Profile	Enhanced Service Mapping Profile
Correlation Information (request-id)	Explicitly added to the data-type	Implicit. Correlation Information appears on the Sample meta-data.
Topic Mapping	One request topic and one reply topic per interface. 2*N for a hierarchy of N interfaces.	One request and one reply topic per interface independent of interface hierarchies.
Type Mapping	Synthesized types compatible with DDS 1.3 compliant implementations.	Use facilities of DDS-XTypes for type descriptions, annotations, and type-compatibility checks.
Discovery	No special extensions.	Robust service discovery as described in sub clause 8.6

### 7.2.5 Interoperability

Client and service interoperability requires both sides to use the same service mapping. Basic and Enhanced Service Mappings can be mixed in an application but for any given service both client and the service side must use the same service mapping. It is therefore considered part of the service interface contract.

The Basic and Enhanced Service mappings are independent of the language binding style. I.e., ~~It~~ is possible for clients and service implementations to communicate using different language binding styles as long as their service mappings match.

### 7.3 Service Definition

A service definition is provided using the following two alternatives.

- Interface:** An interface is a description of the methods/operations and attributes the service implements. It is a *provided* interface. A service may implement one or more interfaces related by inheritance (single or multiple).
- A Pair of Types:** A service specification may simply include a pair of request and reply types. The request and reply types may be the same. The pair of types may not correspond to an interface. However, all service descriptions correspond to a pair of types. In that sense the pair-of-types mechanism of defining a service is strictly more general than interfaces.

This specification uses OMG Interface Definition Language (IDL) or Java 1.5 as a concrete syntax to define services with either of the mechanisms above.

### 7.3.1 Service Definition in IDL

This specification uses the interface definition syntax specified in [IDL35]. Additionally, annotations are supported to provide extra information. Service definition in IDL does not specify whether an operation is synchronous or asynchronous, which is a run-time concern and not intrinsic to the interface contract. Therefore, this specification provides synchronous and asynchronous invocation capabilities only at the language binding level.

**Non-normative:** The definition of the IDL syntax as part of this specification is a transient situation. Once IDL 4.0 is adopted this specification will be able to simply reference the appropriate IDL syntax building blocks defined in IDL 4.0.

#### 7.3.1.1 Service Definition in IDL for the Basic Service Mapping

The BNF grammar used to define the IDL syntax uses the same production rules as in sub clause 7.4 (IDL Grammar) in the [IDL35] specification and sub clause 7.3.1.12.1 (New Productions) of the [DDS-XTypes] specification.

The [IDL35]-3-5 grammar shall be modified with the productions shown below. These productions are numbered using the same numbers as in the [IDL35]-3-5 document.

Note, [ ] represents optional.

(1) **<specification>** ::= **<definition>+**

(2) **<definition>** ::= **<type\_dcl>** “;” **<ann\_appl\_post>**  
| **<const\_dcl>** “;”  
| **<except\_dcl>** “;”  
| **<interface>** “;”  
| **<module>** “;”  
| **<value>** “;”  
| **<annotation>** “;” **<ann\_appl\_post>**

(7) **<interface\_header>** ::= [ **<annotation>** ] “interface” **<identifier>**  
[ **<interface\_inheritance\_spec>** ]

(9) **<export>** ::= **<attr\_dcl>** “;”  
| **<op\_dcl>** “;”

(42) <type\_dcl> ::= [ <annotation> ] “typedef” <type\_declarator>  
| [ <annotation> ] <struct\_type>  
| <union\_type>  
| <enum\_type>  
| “native” <simple\_declarator>  
| <constr\_forward\_decl>

(87) <op\_dcl> ::= [ <annotation> ] <op\_type\_spec> <identifier> <parameter\_dcls>  
[ <raises\_expr> ]

(91) <param\_dcl> ::= [ <annotation> ] <param\_attribute> <param\_type\_spec>  
<simple\_declarator>

(104) <readonly\_attr\_spec> ::= [ <annotation> ] “readonly” “attribute”  
<param\_type\_spec> <readonly\_attr\_declarator>

(106) <attr\_spec> ::= [ <annotation> ] “attribute” <param\_type\_spec>  
<attr\_declarator>

The <annotations> production used above is defined in sub clause 7.3.1.12.1 of the [DDS-XTypes] specification.

## Design Rationale (non-normative)

[\[Issue DDSRPC -7: Editorial corrections in the spec document\]](#)

The table below provides the justification for the modified production rules:

Reference	Origin	Explanation
(1)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	This is the root production rule. Modified to remove the CORBA-specific import statement.
(2)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to remove the productions for related to CORBA Repository Identity and CCM. Specifically <type_id_dcl>, <type_prefix_dcl>, <event>, <component>, and <home_dcl> The modified rule also adds support for annotation declarations. The <annotation> and <ann_appl_post> productions are defined in sub clause 7.3.1.12.1 of the [DDS-XTypes] specification.
(7)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to add support for interface annotations The <annotation> production is defined in sub clause 7.3.1.12.1 of the [DDS-XTypes] specification
(9)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to remove productions related to CORBA Repository Identity. Specifically <type_id_dcl> and <type_prefix_dcl> This production also removes the rules that allow embedding declarations of types, constants, and exceptions within an interface. Specifically the <type_dcl>,   <const_dcl>, and   <except_dcl>
(42)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Added <annotation> production at the beginning of struct and typedef declarators. This allows a structured type to be a request or reply type.
(87)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to add support for annotations on operations. Removed the CORBA-specific “oneway” modifier and the “context” expressions.
(91)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to add support for annotations on the operation parameters
(104)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to add support for annotations on read-only attributes
(106)	<del>IDL</del> <a href="#">3.5[IDL35]</a>	Modified to add support for annotations on attributes
DDS-XTypes	[DDS-XTypes] sub clause 7.3.1.12.2	These productions add support for annotating types and the new IDL types defined in the [DDS-XTypes] specification.

The use of the <annotations> production from DDS-XTypes does not mean that the underlying DDS implementation needs to support DDS-XTypes. The Basic Service Mapping uses annotations only for interface declarations and not on regular type declarations. These interface annotations are resolved in the mapping such that the resulting IDL used by DDS does not have annotations.

### 7.3.1.2 Service Definition in IDL for the Enhanced Service Mapping

The Enhanced Service Mapping allows use of the full type-system defined in the [DDS-XTypes] specification in the declaration of interface attributes, operation parameters and return values.

The Enhanced Service Mapping extends the IDL productions defined in the Basic Service Mapping with all the productions (i.e., not just related to annotations) in sub clause 7.3.1.12.1 (New Productions) of the DDS-XTypes specification.

In addition, the Enhanced Service Mapping also uses all the modified productions defined in sub clause 7.3.1.12.2 (Modified Productions) of the [DDS-Xtypes] specification with the exception of the production for <definition>, which shall remain, as defined for the Basic Service Mapping.

### 7.3.1.3 Example of an Interface in IDL (Non-normative)

```
module robot {
  exception TooFast {};
  enum Command { START_COMMAND, STOP_COMMAND };
  struct Status {
    string msg;
  };
  @DDSService
  interface RobotControl {
    void command(Command com);
    float setSpeed(float speed) raises (TooFast);
    float getSpeed();
    void getStatus(out Status status);
  };
}; //module robot
```

### 7.3.1.4 Service Definition in IDL Using a Pair of Types

A service definition may simply include a pair of types, which may be the same. The request and reply types shall be marked as such using the @RPCRequestType and @RPCReplyType annotations. Only struct types shall be marked as request/reply types.

In the Basic Service Mapping, the types annotated as `@RPCRequestType` shall have a member named `header` of type `dds::rpc::RequestHeader` and the types annotated as `@RPCReplyType` shall have a member named `header` of type `dds::rpc::RequestHeader`. See sub clause 7.5.1.1.1 for the request and reply header types. When using the Enhanced Service Mapping, the annotations are not necessary and the special data members must not be defined.

### 7.3.2 Service Definition in Java

The BNF grammar used to define the Java syntax used in [Java-Grammar]. Conforming implementations shall support the syntax generated by the following modified productions from the Java grammar.

Note, [ ] represents optional and { } represents zero or more occurrences.

InterfaceDeclaration:

```
NormalInterfaceDeclaration
```

NormalInterfaceDeclaration:

```
interface Identifier [extends TypeList] InterfaceBody
```

InterfaceBody:

```
{ InterfaceBodyDeclaration {InterfaceBodyDeclaration} }
```

InterfaceMemberDecl:

```
InterfaceMethodOrFieldDecl
```

```
void Identifier VoidInterfaceMethodDeclaratorRest
```

```
InterfaceDeclaration
```

```
ClassDeclaration
```

NormalClassDeclaration:

```
class Identifier [extends Type] [implements TypeList] ClassBody
```

ClassBody:

```
{ ClassBodyDeclaration {ClassBodyDeclaration} }
```

ClassBodyDeclaration:

```
;
```

```
{Modifier} MemberDecl
```

MemberDecl:

```
MethodOrFieldDecl
```

MethodOrFieldRest:

```
VariableDeclaratorRest
```

### Design Rationale (non-normative)

The table below provides the justification for the modified production rules:

<i>Name</i>	<i>Origin</i>	<i>Explanation</i>
InterfaceDeclaration	Java 1.5	Removed annotation type declaration.
NormalInterfaceDeclaration	Java 1.5	Removed generic type parameters.
InterfaceBody	Java 1.5	At least one method must be present in an interface. Note, Java allows empty (marker) interfaces.
InterfaceMemberDecl	Java 1.5	Removed generic method declaration.
NormalClassDeclaration	Java 1.5	Removed generic type parameters.
ClassBody	Java 1.5	At least one data member must be defined in the class body. Note, Java allows empty classes.
ClassBodyDeclaration	Java 1.5	Removed Java's static block support.
MemberDecl	Java 1.5	Removed method (generic or otherwise) declarator, constructor declarator, nested interface and class declarators. This specification shall support data member declarations inside a Java class.
MethodOrFieldRest	Java 1.5	Removed method declarator. This specification shall support data member declarations inside a Java class.

Formatted: Font: 10 pt

*In*, *out*, and *inout* parameters are specified using the @in, @out and @inout annotations. By default the parameters are read only, and the use of @in is optional. One or more operations may be marked oneway using the @oneway annotation.

#### 7.3.2.1 Example of an interface in Java (Non-normative)

```
public class TooFast extends Exception
{
}

@DDSService
public interface RobotControl
{
    void command(Command com);
}
```

```

float setSpeed(float speed) throws TooFast;
float getSpeed();
void getStatus(@out Status status);
};

```

### 7.3.2.2 Service Definition in Java Using a Pair of Types

A service definition may simply include a pair of types, which may be the same. The request and reply types shall be marked as such using the `@RPCRequestType` and `@RPCReplyType` annotations. Only `class` types shall be marked as request/reply types.

In the Basic Service Mapping, the types annotated as `@RPCRequestType` shall have a member named `header` of type `dds.rpc.RequestHeader` and the types annotated as `@RPCReplyType` shall have a member named `header` of type `dds.rpc.RequestHeader`. See sub clause 7.5.1.1.1 for the request and reply header types.

When using the Enhanced Service Mapping, the annotations are not necessary and the special data members must not be defined.

## 7.4 Mapping Service Specification to DDS Topics

### 7.4.1 Rules for Synthesizing DDS Topic Names

Request and reply topic names use the following BNF grammar.

```

<topic_name> ::= <interface_name> “_” <service_name> “_” [ “Request” | “Reply” ]
                | <user_def_alpha_num>
<service_name> ::= “Service”
                | <user_def_alpha_num>
<user_def_alpha_num> ::= ^[[:a1num:]]_]+$

```

[\[Issue DDSRPC -11: modules in IDL\]](#) Topic name is either a user-defined string literal or a composite string consisting `<interface_name>` and `<service_name>`. The `<interface_name>` non-terminal represents the [unqualified-fully-qualified](#) name of the interface, which is captured automatically for interface-based service definitions. [A fully qualified interface-name includes concatenation of module names separates by underscores followed by the name of the interface.](#) The `<service_name>` non-terminal may be user-supplied. When it is not, it defaults to “Service”. If the `<service_name>` is specified by the user, “Request” and “Reply” topic suffixes are used automatically. When `<service_name>` and user-defined topic names are both provided by the [used user](#), the user-defined topic names take precedence.

For the request-reply style language binding, `<interface_name>` and the following underscore shall not be captured automatically.

Note that the `<user_def_alpha_num>` non-terminal is a regular expression that includes alphanumeric characters (a-zA-Z0-9), underscore and space.

## 7.4.2 Basic Service Mapping

The Basic Service mapping maps every interface to a request topic and a reply topic. It provides three alternative mechanisms to specify the names of the topics. It is possible to use different mechanism at the client and server sides. However, to ensure successful end-point matching, the topic names must match.

In case of an interface inheritance hierarchy, including multiple inheritance, each interface in the hierarchy shall be mapped to its own pair of request and reply topics.

### 7.4.2.1 Default Topic Names

The default topic names are synthesized using the rules defined in sub clause 7.4.1.

### 7.4.2.2 Specifying Topic Names using Annotations

Interfaces and the request/reply types may be annotated to specify the names of the request and reply topics. `@DDSRequestTopic` and `@DDSReplyTopic` annotations are pre-defined for this purpose. They are defined using the [DDS-XTypes] notation as follows:

```
module dds {
  module rpc {
    \[Issue DDSRPC\_-19: Annotation scope\]
    @Annotation@annotation
    local interface DDSRequestTopic {
      attribute string name;
    };

    @Annotation@annotation
    local interface DDSReplyTopic {
      attribute string name;
    };
  };
};
```

Note that support for [DDS-XTypes] in the underlying DDS implementation is not required to interpret the annotations. These annotations simply control the generated DDS wrapper code.

**Non-Normative Example:** The `RobotControl` interface may use one or both of the annotations shown below.

```
@DDSService
@DDSRequestTopic(name="RobotRequestTopic")
```

```
@DDSReplyTopic(name="RobotReplyTopic")

interface RobotControl
{
    void command(Command com);

    ...
}
```

### 7.4.2.3 Specifying Topic Names at Run-time

DDS Topic names may also be specified at run-time. The `ServiceParams`, `ClientParams`, `RequesterParams`, and `ReplierParams` classes (sub clause 7.11.1.4) provide functions to specify the service name and the topic name suffix. When used as such, the rules defined in sub clause 7.4.1 apply.

When more than one method of specifying topic names is used, the run-time specification shall take precedence over the IDL annotations and the default mechanism in that order.

### 7.4.3 The Enhanced Service Mapping

To support single and multiple inheritance of interfaces, the Enhanced Service mapping introduces a notion called “topic aliases”. A topic-alias is an alternative name for a topic. A topic may have one or more topic aliases. A topic-alias does not introduce a new topic. It simply indicates the fact that a given topic may be known by different names. Topic aliases are announced during the endpoint discovery protocol using either of the `PublicationBuiltinTopicDataExt` and `SubscriptionBuiltinTopicDataExt` structures described in in sub clause 7.6.2.1.

The Enhanced Service Mapping shall map an interface to exactly one request topic and a reply topic. The names of the topics are obtained using the rules defined in sub clause 7.4.1. In case of single and multiple inheritance, the request and reply topics shall additionally have topic-aliases, which are obtained using the rules in sub clause 7.4.1 for each parent interface.

**Non-normative example:** The following example shows the topic names and topic-aliases for the Calculator hierarchy while using the function-call style language binding. Depending upon whether the user has supplied the service name and/or topic-suffixes, different outcomes are produced.

		Topic name	Topic aliases
<pre>interface Adder { ... }; interface Subtractor { ... }; interface Calculator : Adder, Subtractor { ... }</pre>			
Everything Default	Request	Calculator_Service_Request	Adder_Service_Request, Subtractor_Service_Request
	Reply	Calculator_Service_Reply	Adder_Service_Reply, Subtractor_Service_Reply
User-defined service name	Request	Calculator_\${servicename}_Request	Adder_\${servicename}_Request, Subtractor_\${servicename}_Request
	Reply	Calculator_\${servicename}_Reply	Adder_\${servicename}_Reply, Subtractor_\${servicename}_Reply
User-defined topic suffixes	Request	Calculator_\${topic-suffix-request}	Adder_\${topic-suffix-request}, Subtractor_\${topic-suffix-request}
	Reply	Calculator_\${topic-suffix-reply}	Adder_\${topic-suffix-reply}, Subtractor_\${topic-suffix-reply}

For the request-reply style language binding, the interfaces name shall not be annexed automatically.

#### 7.4.3.1 Default Topic Names

The default topic names are synthesized as described above.

#### 7.4.3.2 Specifying Topic Names Using Annotations

Interfaces and the request/reply types may be annotated to specify the names of the request and reply topics. The same built-in @DDSRequestTopic and @DDSReplyTopic annotations defined in the Basic Service Mapping may be used for this purpose.

#### 7.4.3.3 Specifying Topic Names at Run-time

DDS Topic names may also be specified at run-time. The ServiceParams, ClientParams, RequesterParams, and ReplierParams classes (sub clause 7.11.1.4) provide functions to

specify the service name and the topic name suffix. When used as such, the rules defined in sub clause 7.4.1 apply.

When more than one method of specifying topic names is used, the run-time specification shall take precedence over the IDL annotations and the default mechanism in that order.

## 7.5 Mapping Service Specification to DDS Topics Types

The *request* and *reply* DDS Topic types shall be synthesized from the interface definition. [\[Issue DDSRPC -19: Annotation Scope. Moved the sentence to 7.5.1.2 as that's the right place for this sentence\]](#)~~To accurately capture the semantics of the method call invocation and return, this specification defines additional built-in annotations. The following annotations are applicable for the Enhanced Service Mapping only.~~

### 7.5.1 Interface Mapping

#### 7.5.1.1 Basic Service Mapping of Interfaces

The Basic Service Mapping maps interfaces to data-types that can be used by DDS version 1.3 compliant implementations, which may lack support for the [DDS-XTypes] specification.

##### 7.5.1.1.1 Common Types

[\[Issue DDSRPC -1: Clarifications and simple technical corrections\]](#)

All the generated types as per the Basic Service Mapping use a set of common types. [Types EntityId\\_t, GUID\\_t, and SequenceNumber\\_t are defined in the \[RTPS\] specification.](#)

```
module dds {  
  
  // The following DDS related types are  
  // borrowed from the RTPS v1.2 specification  
  
  typedef octet GuidPrefix_t[12];  
  
  
  struct EntityId_t {  
    octet entityKey[3];  
    octet entityKind;  
  };  
  
  struct GUID_t {  
    GuidPrefix_t guidPrefix;  
    EntityId_t entityId;  
  };  
  
};
```

Formatted: Font: (Default) Courier New, 10 pt

Formatted: Font: (Default) Courier New, 10 pt

Formatted: Font: (Default) Courier New, 10 pt

```
struct SequenceNumber_t {
    long high;
    unsigned long low;
};

struct SampleIdentity {
    GUID_t writer_guid;
    SequenceNumber_t sequence_number;
};
```

```
module rpc {
typedef octet UnknownOperation;
typedef octet UnknownException;
typedef octet UnusedMember;
```

```
enum RemoteExceptionCode t
{
REMOTE_EX_OK,
REMOTE_EX_UNSUPPORTED,
REMOTE_EX_INVALID_ARGUMENT,
REMOTE_EX_OUT_OF_RESOURCES,
REMOTE_EX_UNKNOWN_OPERATION,
REMOTE_EX_UNKNOWN_EXCEPTION
};enum RemoteExceptionCode_t; // defined in sub clause 8.5.2
```

```
typedef string<255> InstanceName;
struct RequestHeader {
    SampleIdentity_t requestId;
string<255> instanceName;
InstanceName instanceName;
```

```

};
struct ReplyHeader {
    dds::SampleIdentity relatedRequestId;
    dds::rpc::RemoteExceptionCode_t remoteEx;
};
} // module rpc
} // module dds

```

### 7.5.1.1.2 The Hashing Algorithm

In the implied IDL definitions in this specification use a HASH function to compute a 32-bit hash of strings. The HASH function shall use the following pseudo-implementation.

```

long HASH(string arg)
{
    octet md5 hash[16];
    md5 hash = compute md5( arg );

    return          md5 hash[0] +
                256* md5 hash[1] +
                256*256* md5 hash[2] +
                256*256*256* md5 hash[3];
}

```

#### [Issue DDSRPC -9: Collisions in Implied IDL]

Conforming implementation are not required to detect collisions of identifier names of the form \* \_Hash\_ as in general they are not detectable because IDL modules can be reopened and a user could add a colliding identifier much later a service interface is defined. Therefore, this specification does not require detection of collision of const identifier names for hashes.

### 7.5.1.1.3 [Issue DDSRPC -15 Missing attribute exception specification mapping|Mapping of Attributes to Implied IDL]

Every attribute in the interface maps to *implied* IDL using the following rules.

1. Each attribute in an interface maps to a pair of IDL operations. `get attribute <attribute-name>` and `set attribute <attribute-name>` in the same interface. It is illegal to have an interface with an attribute named `<attribute-name>` and user-defined operations named `get attribute <attribute-name>` and `set attribute <attribute-name>`.

Formatted: Font: (Default) Courier New

#### 7.5.1.1-27.5.1.1.4 Mapping of Operations to the Request Topic Types

The mapping of an interface operation to a request type is defined according to the following rules. In these rules the token `${interfaceName}` shall be replaced with the name of the interface and the token `${operationName}_` shall be replaced with the name of the operation. The substituted names are not fully qualified. I.e., any module prefixes shall be removed.

1. Each operation in the interface shall map to an *In* structure with name "`${interfaceName}_${operationName}_In`".
2. The *In* structure shall be defined within the same module as the original interface.
3. The *In* structure shall contain as members the *in* and *inout* parameters defined in the operation signature.
  - a. The members shall appear in the same order as the parameters in the operation, starting from the left.
  - b. The names of the members shall be the same as the formal parameter names.
  - c. If an operation has no *in* and *inout* parameters the resulting structure shall contain a single member of type `UnusedMember` and name "dummy".

**Non-normative Example:** The operations in the `RobotControl` interface defined in sub clause 7.3.1.3 shall map to the following *In* structures.

```
module robot {  
  
    struct RobotControl_command_In {  
        Command com;  
    };  
  
    struct RobotControl_setSpeed_In {
```

```

float speed;
};

struct RobotControl_getSpeed_In {
    dds::rpc::UnusedMember dummy;
};

struct RobotControl_getStatus_In {
    dds::rpc::UnusedMember dummy;
};
}

```

#### 7.5.1.1.37.5.1.1.5 Mapping of Operations to the Reply Topic Types

Each operation in the interface shall map to an *Out* structure and a *Result* union. The following rules define the *Out* structure.

1. The name of the *Out* structure shall be “\${interfaceName}\_\${operationName}\_Out”.
2. The *Out* structure shall be defined within the same module as the original interface.
3. The *Out* structure shall contain as members the *out* and *inout* parameters defined in the operation signature. In addition it may contain a member named “return\_”.
  - a. The *Out* structure shall include one member for each *out* and *inout* parameter in the operation signature.
    - i. The members shall appear in the same order as the parameters in the operation, starting from the left.
    - ii. The name of the members shall be the same as the formal parameter names.
  - b. If the operation defines a non-void return value the *Out* structure shall have its last member named “return\_”. The type of the “return\_” member shall be the return type of the operation. In the case where the function does not define a return value this member shall not be present. Issue DDSRPC -9: Collisions in Implied IDL If an operation has an out argument named `return` and the operation has a regular return value, the regular return value in the *Out* structure shall be represented as `return_N` member of the appropriate type where N is the first integer in the range 1 to 2<sup>31</sup> that avoids the collision.
  - c. If the operation has no return value, no *out/inout* parameters, the *Out* structure shall contain a single member named “dummy” of type `dds::rpc::UnusedMember`.

**Non-normative Example:** The operations defined in the `RobotControl` interface defined in sub clause 7.3.1.3 map to the following *Out* structures.

Formatted: Font: (Default) Courier New

Formatted: Font: Italic

Formatted: Font: (Default) Courier New

```

module robot {
struct RobotControl_command_Out {
    dds::rpc::UnusedMember dummy;
};

struct RobotControl_setSpeed_Out {
    float return_;
};

struct RobotControl_getSpeed_Out {
    float return_;
};

struct RobotControl_getStatus_Out {
    Status status;
};
}

```

The following rules define the *Result* union.

1. The *Result* union name shall be “\${interfaceName}\_\${operationName}\_Result”.
2. The *Result* union discriminator type shall be `long`.
3. ~~[Issue DDSRPC -13: Potentially redundant UnknownEx] The *Result* union shall have a default case label containing a member named “unknownEx” of type `dds::rpe::UnknownException`.~~
4. The *Result* union shall have a case with label `dds::RETCODE_OK` which is used to represent a successful return.
  - a. This case label shall contain a single member with name “result” and type `${interfaceName}_${operationName}_Out`.
5. For each exception type raised by the operation,
  - a. A constant of type `long` and with name “\${exceptionType}\_Ex\_Hash” shall be available in the same namespace as the interface is defined in.
  - b. The value of the constant shall be the `HASH` of the fully qualified name of the exception type where module separator to be used is “::” (2 colons).
6. The union shall have a case label for each exception declared as a possible outcome of the operation.
  - a. The integral value of the case label shall be `${exceptionType}_Ex_Hash`.
  - b. The case label shall contain a single member with name synthesized as the lower-case of the exception name with the suffix “\_ex” added.

- c. The type associated with the case member shall be the exception type.

**Non-normative Example:** The operations defined in the RobotControl interface defined in sub clause 7.3.1.3 map to the following *Result* unions.

[Issue DDSRPC -13: Potentially redundant UnknownEx]

```
module robot {

const long TooFast_Ex_Hash = HASH("TooFast");

union RobotControl_command_Result switch(long)
{
—default:
—dds::rpc::UnknownException unknownEx,
—
case dds::RETCODE_OK:
    RobotControl_command_Out result;
};

union RobotControl_setSpeed_Result switch(long)
{
—default:
—dds::rpc::UnknownException unknownEx,
—
case dds::RETCODE_OK:
    RobotControl_setSpeed_Out result;

case TooFast_Ex_Hash:
    TooFast toofast_ex;
};

union RobotControl_getSpeed_Result switch(long)
{
—default:
—dds::rpc::UnknownException unknownEx,
```

```

case dds::RETCODE_OK:
    RobotControl_getSpeed_Out result;
};

union RobotControl_getStatus_Result switch(long)
{

default:
    dds::rpe::UnknownException_unknownEx;

case dds::RETCODE_OK:
    RobotControl_getStatus_Out result;
};

} // module robot

```

[\[Issue DDSRPC -9: Collisions in Implied IDL. Moved this dangling paragraph to to its own section 7.5.1.1.2\]](#)~~In the above IDL the short hand HASH(arg) is used for clarity. In the actual IDL it shall be substituted with the actual value computed according to the formula:~~

```

long HASH(string arg)
+

octet md5_hash[16];
md5_hash = compute_md5( arg );

return
    md5_hash[0] +
    256* md5_hash[1] +
    256*256* md5_hash[2] +
    256*256*256* md5_hash[3];
+

```

#### [7.5.1.1.4](#) [7.5.1.1.6](#) **Mapping of Interfaces to the Request Topic Types**

Each interface shall map to a *Call* union and a *Request* structure. The following rules define the *Call* union.

1. The *Call* union name shall be “\${interfaceName}\_Call” in the same module as the interface.

2. The *Call* union discriminator type shall be of type long.
3. The *Call* union shall have a default case label containing a member named “unknownOp” of type `dds::rpc::UnknownOperation`. [**Non-normative design rationale:** Due to interface evolution a client that uses new interface may end up calling a service that implements a previous version of the interface. In that case, the discriminator value will not match any of the existing cases and hence will default to unknown, which should be recognized by the service implementation.]
4. For each operation in the interface, an integral constant of type long and name “\${interfaceName}\_\${operationName}\_Hash” shall be present in the same module as the interface. The value of this constant is the HASH of unqualified \${operationName}.
5. The *Call* union shall have a case label for each operation in the interface.
  - a. The integral value of the case label shall be the HASH of \${operationName}.
  - b. The member name for the case label shall be the operation name.
  - c. The type for the case label member shall be \${interfaceName}\_\${operationName}\_In as defined in sub clause 7.5.1.1.2.

**Non-normative Example:** The `RobotControl` interface defined in sub clause 7.3.1.3 shall map to the following union `RobotControl_Call`.

```

module robot {

const long RobotControl_command_Hash    = HASH("command");
const long RobotControl_setSpeed_Hash   = HASH("setSpeed");
const long RobotControl_getSpeed_Hash   = HASH("getSpeed");
const long RobotControl_getStatus_Hash  = HASH("getStatus");

union RobotControl_Call switch(long)
{
    default:
        dds::rpc::UnknownOperation unknownOp;

    case RobotControl_command_Hash:
        RobotControl_command_In command;

    case RobotControl_setSpeed_Hash:
        RobotControl_setSpeed_In setSpeed;
}

```

```

    case RobotControl_getSpeed_Hash:
        RobotControl_getSpeed_In getSpeed;

    case RobotControl_getStatus_Hash:
        RobotControl_getStatus_In getStatus;
};
}

```

The following rules define the *Request* structure.

1. The name of *Request* structure shall be “\${interfaceName}\_Request” in the same module as the interface.
2. The *Request* structure shall have two members:
  - a. The first member of the *Request* structure shall be named “header” and be of type `dds::rpc::RequestHeader`.
  - b. The second member of the *Request* structure shall be named “data” and be of type `${interfaceName}_Call`.

**Non-normative Example:** The `RobotControl` interface defined in sub clause 7.3.1.3 shall map to `RobotControl_Request` defined below.

```

module robot {

    struct RobotControl_Request {
        dds::rpc::RequestHeader header;
        RobotControl_Call      data;
    };
}

```

#### [7.5.1.1.5](#) [7.5.1.1.7](#) Mapping of Interfaces to the Reply Topic Types

Each interface shall map to a *Return* union and a *Reply* structure.

The following rules define the *Return* union.

1. The *Return* union name shall be “\${interfaceName}\_Return” in the same module as the interface.

2. The *Return* union discriminator type shall be of type `long`.
3. The *Return* union shall have a default case label containing a member named “unknownOp” of type `dds::rpc::UnknownOperation`. **[Non-normative rationale:** Unknown operation errors should not be reported back using this member. The `ReplyHeader.remoteEx` member should be used for that. The only reason the `unknownOp` member is used because it is a good practice to define a default for a union.]
4. For each operation,
  - a. A constant of type `long` and with name “\${interfaceName}\_\${operationName}\_Hash” shall be available in the same namespace as the interface is defined in.
  - b. The value of the constant shall be the HASH of the name of the operation (not qualified).
5. The *Return* union shall have a case label for each operation in the interface:
  - a. The integral value of the case label shall be \${interfaceName}\_\${operationName}\_Hash as computed using the HASH algorithm of the unqualified name of the operation.
  - b. The member name for the case label shall be the operation name and the type shall be \${interfaceName}\_\${operationName}\_Result.

**Non-normative Example:** The `RobotControl` interface defined in sub clause 7.3.1.3 shall map to the union `RobotControl_Return` defined below:

```

union RobotControl_Return switch(long)
{
  default:
    dds::rpc::UnknownOperation unknownOp;

  case RobotControl_command_Hash:
    RobotControl_command_Result command;

  case RobotControl_setSpeed_Hash:
    RobotControl_setSpeed_Result setSpeed;

  case RobotControl_getSpeed_Hash:
    RobotControl_getSpeed_Result getSpeed;

  case RobotControl_getStatus_Hash:

```

```
RobotControl_getStatus_Result getStatus;  
};
```

The following rules define the *Reply* structure.

1. The *Reply* structure name shall be “\${interfaceName}\_Reply”.
2. The *Reply* structure shall be defined within the same module as the original interface.
3. The *Reply* structure shall have two members:
  - a. The first member of the *Reply* structure shall be named “header” and be of type `dds::rpc::ReplyHeader`.
  - b. The second member of the *Reply* type shall be named “data” and be of type `${interfaceName}_Return`.

**Non-normative Example:** The `RobotControl` interface defined in sub clause 7.3.1.3 shall map to the structure `RobotControl_Reply` defined below:

```
struct RobotControl_Reply {  
    dds::rpc::ReplyHeader header;  
    RobotControl_Return    reply;  
};
```

#### [7.5.1.1.6](#) [7.5.1.1.8](#) Mapping of inherited Interfaces to the Request and Reply Topic Types

Inheritance has no effect on the generated structures and unions. A DDS service that implements a derived interface uses two topics for every interface in the hierarchy. As a result, a service implementing a hierarchy of *N* interfaces, shall have *N* request topics and *N* reply topics. Consequently, it will necessitate *N* DataWriters and *N* DataReaders. The types and the topic names are obtained as specified in sub clause 7.4.2. The *Request* and *Reply* types for a derived interface includes operations defined only in the derived interface.

**Non-normative Example:** The Basic Service Mapping for the Calculator interface is shown below.

```
interface Adder {  
    long add(long a, long b);  
};  
interface Subtractor {  
    long sub(long a, long b);  
};  
interface Calculator : Adder, Subtractor {
```

```
void on();
void off();
};
```

```
struct Adder_add_In {
    long a;
    long b;
};

struct Adder_add_Out {
    long return_;
};

union Adder_add_Result switch (long) {
default:
dds::rpc::UnknownException unknownEx;

    case dds::rpc::REMOTE_EX_OK:
        Adder_add_Out result;
};

const long Adder_add_Hash = HASH("add");

union Adder_Call switch (long) {
    default:
        dds::rpc::UnknownOperation unknownOp;

    case Adder_add_Hash:
        Adder_add_In add;
};

struct Adder_Request {
    dds::rpc::RequestHeader header;
    Adder_Call data;
};
```

```

};

union Adder_Return switch(long) {
    default:
        UnknownOperation unknownOp;

    case Adder_add_Hash:
        Adder_add_Result add;
};

struct Adder_Reply {
    dds::rpc::ReplyHeader header;
    Adder_Return data;
};

struct Subtractor_sub_In {
    long a;
    long b;
};

struct Subtractor_sub_Out {
    long return_;
};

union Subtractor_sub_Result switch (long) {
    default:
        dds::rpc::UnknownException unknownEx;
    case dds::rpc::REMOTE_EX_OK:
        Subtractor_sub_Out result;
};
const long Subtractor_sub_Hash = HASH("sub");

union Subtractor_Call switch (long) {
    default:

```

```

    dds::rpc::UnknownOperation unknownOp;

    case Subtractor_sub_Hash:
        Subtractro_sub_In sub;
};
struct Subtractor_Request {
    dds::rpc::RequestHeader header;
    Subtractor_Call data;
};
union Subtractor_Return switch(long) {
    default:
        dds::rpc::UnknownOperation unknownOp;

    case Subtractor_sub_Hash:
        Subtractor_sub_Result sub;
};

struct Subtractor_Reply {
    dds::rpc::ReplyHeader header;
    Subtractor_Return data;
};

struct Calculator_on_In {
    dds::rpc::UnusedMember dummy;
};

struct Calculator_off_In {
    dds::rpc::UnusedMember dummy;
};

struct Calculator_on_Out {
    dds::rpc::UnusedMember dummy;
};

```

```

};

union Calculator_on_Result switch(long) {
default:
dds::rpc::UnknownException unknownEx;
    case dds::rpc::REMOTE_EX_OK:
        Calculator_on_Out result;
};

struct Calculator_off_Out {
    dds::rpc::UnusedMember dummy;
};

union Calculator_off_Result switch(long) {
default:
dds::rpc::UnknownException unknownEx;

    case dds::rpc::REMOTE_EX_OK:
        Calculator_off_Out result;
};

const long Calculator_on_Hash = HASH("on");
const long Calculator_off_Hash = HASH("off");

union Calculator_Call switch (long) {
    default:
        dds::rpc::UnknownOperation unknownOp;

    case Calculator_on_Hash:
        Calculator_on_In on;

    case Calculator_off_Hash:
        Calculator_off_In off;
};

```

```

};
struct Calculator_Request {
    dds::rpc::RequestHeader header;
    Calculator_Call          data;
};

union Calculator_Return switch(long) {
    default:
        dds::rpc::UnknownOperation unknownOp;

    case Calculator_on_Hash:
        Calculator_on_Result on;

    case Calculator_off_Hash:
        Calculator_off_Result off;
};

struct Calculator_Reply {
    dds::rpc::ReplyHeader header;
    Calculator_Return      data;
};

```

### 7.5.1.2 Enhanced Service Mapping of Interfaces

[\[Issue DDSRPC -19: Annotation Scope. Moved the sentence from the beginning of 7.5 as this is the right place for this sentence\]](#) [To accurately capture the semantics of the method call invocation and return, this specification defines additional built-in annotations. The following annotations are applicable for the Enhanced Service Mapping only.](#) The Enhanced Service Mapping uses the [DDS-XTypes] type system in addition to the annotations defined in sub clause 7.5.1.2.1.

#### 7.5.1.2.1 Annotations for the Enhanced Service Mapping

All annotations below are defined in the `dds::rpc` module.

##### 7.5.1.2.1.1 @Choice Annotation

This specification defines an `@Choice` annotation to capture the semantics of a `union` without using a discriminator. Using unions to indicate which operation is being invoked is brittle. Operations in an interface have set semantics and have no ordering constraints. Union, however,

enforces strict association with discriminator values, which are too strict for set semantics. Further, use of unions leads to ambiguities in case of multiple inheritance of interfaces.

The @Choice annotation is a placeholder annotation defined as follows.

```
@Annotation @annotation local interface Choice { };
```

The @Choice annotation is allowed on structures only. When present, the structure shall be interpreted as if the structure had the @Extensibility(MUTABLE\_EXTENSIBILITY) annotation and all the members of the structure had the @Optional annotation. Furthermore, exactly one member shall be present at any given time.

This specification uses the semantics of @Choice for the *return* topic type and to differentiate between normal and exceptional return from a remote method call.

#### 7.5.1.2.1.2 @AutoId Annotation

The @AutoId annotation shall be allowed on structures and data members. The structures of the topic types synthesized from the interface shall be annotated as @AutoId.

The @AutoId annotation indicates that the member-id of each member shall be computed using the HASH algorithm (defined in sub clause 7.5.1.1.2) applied to the name of the member. As IDL does not support overloading, no two members will have the same name. Consequently, the member ids of two members will be different, unless a hash-collision occurs, which shall be detected by the code generator that processes the IDL interface. Using the MD5 hash for the member id also ensures that the topic types synthesized from the interface definitions are not subject to the order of operation declaration or interface inheritance. Note that the order of interface inheritance is irrelevant to the semantics of an interface. Further, it supports interface evolution (including new operations, operation reorder and new base interfaces) without changing the member ids. Issue DDSRPC -9: Collisions in the implied IDL. The collisions of member-ids produced as a result of @autoId annotation must be detected. If a structure annotated as @autoId has a hash collision due to two or more member names map to the same hash-code, the collision shall be reported as an error.

#### 7.5.1.2.1.3 @Empty Annotation

This specification uses empty IDL structures to capture operations that do not accept any parameters. IDL does not support empty structures. @Empty annotation has been introduced to simplify the mapping rules and support operations that take no arguments. Empty structures, however, are used to maintain consistency between the *call* and *return* structures. Furthermore, eliminating empty structures in the synthesized topic types is undesirable because two or more operations may be empty in which case it becomes ambiguous. The @Empty annotation allows a structure to be empty. The code synthesized from an empty structure is implementation dependent.

#### 7.5.1.2.1.4 @Mutable Annotation

This annotation shall be allowed on interface operations. It controls the type-mapping for the operation parameters and return value. By default, adding and removing operation parameters would break compatibility with the previous interface. The use of the @Mutable operation changes the type declaration of the synthesized call and return structures so that they are declared with the @Extensibility(MUTABLE\_EXTENSIBILITY) annotation.

Formatted: Font: (Default) Courier New, 12 pt

Formatted: Font: (Default) Times New Roman, 12 pt

Formatted: Font: 12 pt

Formatted: Font: (Default) Times New Roman, 12 pt

#### 7.5.1.2.2 Mapping of Operations to the Request Topic Types

The mapping for interface operations is same as defined in sub clause 7.5.1.1.2 with the following additional rules.

If the operation has the `@Mutable` annotation, then the synthesized *In* structure shall have the annotation `@Extensibility(MUTABLE_EXTENSIBILITY)`

For example, please see sub clause 7.5.1.1.2.

#### 7.5.1.2.3 Mapping of Operations to the Reply Topic Types

Each operation in the interface shall map to an *Out* structure and a *Result* structure. The rules for mapping the *Out* structure is identical to that defined in sub clause ~~7.5.1.1.57-5.1.1.3~~ with the following additional rule.

1. If the operation has the `@Mutable` annotation, then the synthesized *Out* structure shall have the annotation `@Extensibility(MUTABLE_EXTENSIBILITY)`

The mapping rules for the *Result* structure are as follows.

2. The *Result* structure name shall be “`{interfaceName}_{operationName}_Result`”.
3. The *Result* structure shall have the annotation `@Choice`.
4. The *Result* structure shall have the annotation `@Autoid`.
5. The *Result* structure shall have a first member with name “result” and with type `{interfaceName}_{operationName}_Out`.
6. The *Result* structure name shall have members for each exception an operation may raise.
  - a. The member name shall be synthesized as the lower-case version of the exception name with the suffix “\_ex” added.
  - b. The type associated with the member shall be the exception type.
7. If the operation has the `@Mutable` annotation, then the synthesized *Result* structure shall have the annotation `@Extensibility(MUTABLE_EXTENSIBILITY)`

**Non-normative example:** The operations defined in the RobotControl interface defined earlier map to the following *Result* structures.

```
@Choice @Autoid
struct RobotControl_command_Result {
    RobotControl_command_Out result;
};

@Choice @Autoid
struct RobotControl_stop_Result {
    RobotControl_getSpeed_Out result;
};

@Choice @Autoid
struct RobotControl_setSpeed_Result {
    RobotControl_setSpeed_Out result;
    TooFast toofast_ex;
};

@Choice @Autoid
struct RobotControl_getSpeed_Result {
    RobotControl_getStatus_Out result;
};
```

#### 7.5.1.2.4 Interface Mapping for the Request Topic Types

Each interface shall map to a *Request* structure.

The following rules define the *Request* structure.

1. The *Request* structure name shall be “\${interfaceName}\_Request”.
2. The *Request* structure shall have the @Choice annotation.
3. The *Request* structure shall have the @Autoid annotation.
4. The *Request* structure shall contain a member for each operation in the interface.
  - a. The member name shall be the operation name.
  - b. The member type shall be \${interfaceName}\_\${operationName}\_In.

**Non-normative example:** The Robotcontrol interface defined earlier shall result in the RobotControl\_Call structure defined below.

```
@Choice @Autoid
struct RobotControl_Request {
    RobotControl_command_In command;
    RobotControl_setSpeed_In setSpeed;
    RobotControl_getSpeed_In getSpeed;
};
```

```
RobotControl_getStatus_In getStatus;
};
```

#### 7.5.1.2.5 Interface Mapping for the Reply Type

Each interface shall map to a *Reply* structure.

The following rules define the *Reply* structure. In these rules the token `${interfaceName}` shall be replaced with the name of the interface:

1. The *Reply* structure name shall be “`${interfaceName}_Reply`”.
2. The *Reply* structure shall have the `@Choice` annotation.
3. The *Reply* structure shall have the `@Autoid` annotation.
4. The *Reply* structure shall contain a member for each operation in the interface.
  - a. The member name shall be the operation name.
  - b. The member type shall be `${interfaceName}_${operationName}_Result`.
5. The *Reply* structure shall contain a member named “remoteEx” of type `dds::rpc::RemoteException_t`. Issue DDSRPC -9: Collisions in Implied IDL If an interface has an operation named `remoteEx` (case-sensitive), the corresponding *Reply* structure shall contain a member named `remoteEx_N` and type `RemoteException_t`, where `N` is the first integer in the range 1 to  $2^{31}$  that avoids the collision.

**Non-normative example:** The `RobotService` interface defined earlier maps to the following structure.

```
@Choice @Autoid
struct RobotControl_Reply {
    RobotControl_command_Result command;
    RobotControl_setSpeed_Result setSpeed;
    RobotControl_getSpeed_Result getSpeed;
    RobotControl_getStatus_Result getStatus;
    dds::rpc::RemoteException_t remoteEx;
};
```

#### 7.5.1.2.6 Mapping of Inherited Interfaces to Request and Reply Topic Types

A derived interface is interpreted as if all the inherited operations are declared in-place in the derived interface. That is, the inheritance structure is *flattened*.

**Non-normative Example:** The Enhanced Service Mapping rules applied to the `Calculator` interface hierarchy results in the following request and reply Topic types.

Formatted: Font: (Default) Courier New

Formatted: Font: Italic

Formatted: Font: (Default) Courier New

Formatted: Font: (Default) Courier New

```
@Autoid
struct Adder_add_In {
    long a;
    long b;
};

@Autoid
struct Adder_add_Out {
    long return_;
};

@Choice @Autoid
struct Adder_add_Result {
    Adder_add_Out result;
};

@Choice @Autoid
struct Adder_Request {
    Adder_add_Result add;
};

@Autoid
struct Subtractor_sub_In {
    long a;
    long b;
};

@Autoid
struct Subtractor_sub_Out {
    long return_;
};

@Choice @Autoid
struct Subtractor_sub_Result {
    Subtractor_sub_Out result;
};
```

```
@Choice @Autoid
struct Subtractor_sub_Reply {
    Subtractor_sub_Result sub;
    dds::rpc::RemoteException_t remoteEx;
};

@Autoid
struct Calculator_on_In {
    long dummy;
};

@Autoid
struct Calculator_off_In {
    long dummy;
};

@Autoid
struct Calculator_on_Out {
    long dummy;
};

@Choice @Autoid
struct Calculator_on_Result {
    Calculator_on_Out result;
};

@Autoid
struct Calculator_off_Out {
    long dummy;
};

@Choice @Autoid
struct Calculator_off_Result {
    Calculator_off_Out result;
};
```

```

@Choice @Autoid
struct Calculator_Request {
    Adder_add_In      add;
    Adder_sub_In      sub;
    Calculator_on_In  on;
    Calculator_off_In off;
};

@Choice @Autoid
struct Calculator_Reply {
    Adder_add_Result      add;
    Subtractor_sub_Result sub;
    Calculator_on_Result  on;
    Calculator_off_Result off;
    dds::rpc::RemoteException_t remoteEx;
};

```

The Enhanced Service Mapping leverages the assignability rules defined in the [DDS-XTypes] specification to ensure that the topic types remain compatible in case of inheritance. A client using the base interface can invoke an operation in a service that implements a derived interface as long as the same topic names are used.

## 7.5.2 Mapping of ~~Remote Exceptions~~ **Error Codes for Basic and Enhanced Profiles**

[Issue DDSRPC\_-23: return code mapping in IDL2C++11]

Error codes are (conceptually) classified as *local* and *remote*. The error codes described in the [DDS] PIM are all *local* error codes. This specification further adds *remote* error codes to communicate service-side error conditions back to the client. ~~Remote Erroneous conditions~~ error codes are ~~reported~~ **represented** using ~~exception codes~~ the `RemoteExceptionCode_t` IDL enumeration below.

```

module dds { module rpc {
enum RemoteExceptionCode_t
{
    REMOTE_EX_OK,
    REMOTE_EX_UNSUPPORTED,
    REMOTE_EX_INVALID_ARGUMENT,

```

**Formatted:** Font: Italic

**Formatted:** Font: Italic

**Formatted:** Font: Italic

**Formatted:** Font: Italic

**Formatted:** Font: (Default) Courier New

```

    REMOTE_EX_OUT_OF_RESOURCES,
    REMOTE_EX_UNKNOWN_OPERATION,
    REMOTE_EX_UNKNOWN_EXCEPTION
};

} // module rpc
} // module dds

```

The remote exception codes have the following meanings.

Remote Exception Code	Meaning
REMOTE_EX_OK	The request was executed successfully.
REMOTE_EX_UNSUPPORTED	Operation is valid but it is unsupported (a.k.a. not implemented)
REMOTE_EX_INVALID_ARGUMENT	<u>[rewording]</u> The value of the parameter <del>that is</del> passed <del>in</del> has an illegal value. (e.g., two options active in a @Choice <u>structure</u> )
REMOTE_EX_OUT_OF_RESOURCES	The remote service ran out of resources while processing the request
REMOTE_EX_UNKNOWN_OPERATION	The operation called is unknown.
REMOTE_EX_UNKNOWN_EXCEPTION	A generic, unspecified exception was raised by the service implementation.

Formatted: Font: +Body (Cambria)

Formatted: Font: (Default) Times New Roman

Both local and remote exception codes map to exceptions in the C++ and Java language bindings defined in Section 7.11. More specifically, all the local return codes map to exceptions as defined in the [DDS-Cxx-PSM] and [DDS-Java-PSM] specifications. Additionally, the following remote exception codes are used to report remote errors. The remote error codes also map to exceptions (in `dds : : rpc` namespace/package) and the details are The language bindings for the remote exception codes is defined provided in sub elause-section 7.11.

Formatted: Font: (Default) Courier New

## 7.6 Discovering and Matching RPC Services

### 7.6.1 Client and Service Discovery for the Basic Service Mapping

The Basic Service Mapping relies on the built-in discovery provided by the underlying [DDS] compliant implementation. It does not use any extensions to the DDS discovery built-in topics.

A client comprises one (or more) DataWriter to send requests and one (or more) DataReader to receive replies. Similarly, a service implementation comprises one (or more) DataReader to receive

requests and one (or more) DataWriter to send replies. The built-in publication and subscription topics are used to discover the DataWriter and DataReader at both sides.

**Non-normative Note:** Service discovery for the Basic Service Mapping is not robust because discovery race conditions can cause the service replies to be lost. The request-topic and reply-topic are two different RTPS sessions that are matched independently by the DDS discovery process. For this reason it is possible for the entities on the request topic to discover each other before the entities on the reply topic discover each other. If such a situation, if a client makes a request before the entities over the reply topic are fully discovered, the client may lose the corresponding replies.

## 7.6.2 Client and Service Discovery for the Enhanced Service Mapping

The Enhanced Service Mapping relies on the built-in discovery service provided by DDS. However, it extends the built-in publication and subscription topic data to avoid the discovery race conditions.

**Non-normative Design Rationale:** The discovery race condition is avoided by announcing the pair of DataReader and DataWriter endpoints (both client-side and service-side) atomically and ensuring that the discovery of entities over the reply topic is complete before a request is sent or received.

A client must ensure that the client-side DataReader has discovered the service-side DataWriter before writing a request to the service-side DataReader. This ensures that the replies received by the client-side DataReader are not discarded.

A service must ensure that service-side DataWriter has discovered the client-side DataReader before a request is accepted by the service-side DataReader. This ensures that the replies in response to a request are not discarded by the service-side DataWriter.

### 7.6.2.1 Extensions to the DDS Discovery Builtin Topics

The [DDS] specification includes the *DCPSPublication* and *DCPSSubscription* builtin topics and corresponding built-in data writers and readers. The data type associated with the *DCPSPublication* built-in Topic is *PublicationBuiltinTopicData*. The data type associated with the *DCPSSubscription* built-in topic is *SubscriptionBuiltinTopicData*. Both are defined in sub clause 2.1.5 of the [DDS] specification. This specification extends both *PublicationBuiltinTopicData* and *SubscriptionBuiltinTopicData*.

**Non-normative Design Rationale:** The extensions specified here are backwards compatible. The [RTPS] specification, which defines the serialization format of *PublicationBuiltinTopicData* and *SubscriptionBuiltinTopicData*, defines what's called a *ParameterList* where each member in the built-in topic data is serialized using CDR but preceded by a *ParameterID* and *Length* of the serialized member. See sub clause 8.3.5.9 of the [RTPS] specification. This serialization format allows the *PublicationBuiltinTopicData* and *SubscriptionBuiltinTopicData* to be extended without breaking interoperability.

#### 7.6.2.1.1 Extended PublicationBuiltinTopicData

This specification defines an extension to the *PublicationBuiltinTopicData* structure. The member types and the *ParameterID* used for the serialization are described below.

<i>Member name</i>	<i>Member type</i>	<i>Parameter ID name</i>	<i>Parameter ID value</i>
service_instance_name	string<256>	PID_SERVICE_INSTANCE_NAME	0x0080
related_datareader_key	GUID_t	PID_RELATED_ENTITY_GUID	0x0081
topic_aliases	sequence<string<256>>	PID_TOPIC_ALIASES	0x0082

[Issue DDSRPC -5: Inconsistent ParameterIDs]

```
@extensibility(MUTABLE_EXTENSIBILITY)
struct PublicationBuiltinTopicDataExt : PublicationBuiltinTopicData {
    @ID(0x00540x0080) string<256> service_instance_name;
    @ID(0x00550x0081) GUID_t related_datareader_key;
    @ID(0x00560x0082) sequence<string<256>> topic_aliases;
};
```

The `service_instance_name` is the instance name specified by the user at the service-side. If none is specified, there is no default value. Likewise, the client-side `DataWriter` shall not include `service_instance_name`.

The `topic_aliases` are as per defined in sub clause 7.4.3. There is no default value.

The `related_datareader_key` shall be set and interpreted according to the following rules:

- When not present the default value for the `related_datareader_key` shall be interpreted as `GUID_UNKNOWN` as defined by sub clause 9.3.1.5 of the [RTPS] specification.
- The `PublicationBuiltinTopicDataExt` that corresponds to the client-side `DataWriter` used for sending requests for a service shall have the `related_datareader_key` set to the `BuiltinTopicKey_t` of the client-side `DataReader` used for receiving the replies.
- The `PublicationBuiltinTopicDataExt` that corresponds to the service-side `DataWriter` used for sending replies shall have the `related_datareader_key` set to the `BuiltinTopicKey_t` of the service-side `DataReader` used to receive the requests.

#### 7.6.2.1.2 Extended SubscriptionBuiltinTopicData

This specification defines an extension to the `SubscriptionBuiltinTopicData` structure. The member types and the `ParameterID` used for the serialization are described below:

<i>Member name</i>	<i>Member type</i>	<i>Parameter ID name</i>	<i>Parameter ID value</i>
--------------------	--------------------	--------------------------	---------------------------

Formatted: Highlight

Formatted: Highlight

Formatted: Highlight

service_instance_name	string<256>	PID_SERVICE_INSTANCE_NAME	<u>0x00540x0080</u>
related_datawriter_key	GUID_t	PID_RELATED_ENTITY_GUID	<u>0x00550x0081</u>
topic_aliases	sequence<string<256>>	PID_TOPIC_ALIASES	<u>0x00560x0082</u>

```
@extensibility(MUTABLE_EXTENSIBILITY)
struct SubscriptionBuiltinTopicDataExt : SubscriptionBuiltinTopicData {
    @ID(0x00540x0080) string<256> service_instance_name;
    @ID(0x00550x0081) GUID_t related_datawriter_key;
    @ID(0x00560x0082) sequence<string<256>> topic_aliases;
};
```

The `service_instance_name` is the instance name specified by the user at the service-side. If none is specified, there is no default value. Likewise, the client-side `DataReader` shall not include `service_instance_name`.

The `topic_aliases` are as per defined in sub clause 7.4.3. There is no default value.

The `related_datawriter_key` shall be set and interpreted according to the following rules:

- When not present the default value for the `related_datawriter_key` shall be interpreted as `GUID_UNKNOWN` as defined by sub clause 9.3.1.5 of the RTPS specification.
- The `SubscriptionBuiltinTopicDataExt` that corresponds to the client-side `DataReader` used to receive replies shall have the `related_datawriter_key` set to the `BuiltinTopicKey_t` of the client-side `DataWriter` used to send the requests to the DDS-RPC Service.
- The `SubscriptionBuiltinTopicDataExt` that corresponds to the service-side `DataReader` used to write replies shall have the `related_datawriter_key` set to the `BuiltinTopicKey_t` of the service-side `DataWriter` used to receive requests.

### 7.6.2.2 Enhanced algorithm for Service Discovery

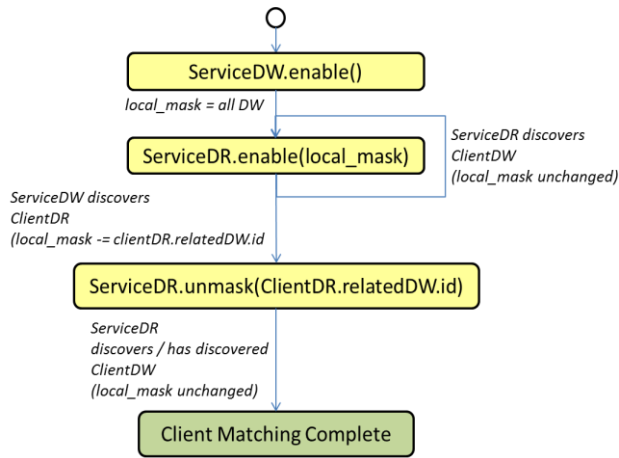

The built-in DDS discovery mechanism ensures that `DataWriters` discover the matching `DataReaders` and vice versa. However to ensure robustness, service discovery must ensure that no replies are lost due to race conditions in the discovery process of the underlying DDS entities. Additional rules shall be used at the client-side `DataWriter` and service-side `DataReader`:

- The client-side `DataWriter` (request `DataWriter`) shall not send out any request to a service `DataReader` unless the client-side `DataReader` (reply `DataReader`) has discovered and matched the corresponding service `DataWriter` (reply `DataWriter`).

- The service-side DataReader (request DataReader) shall reject requests from a client DataWriter (request DataWriter) as long as the service-side DataWriter (reply DataWriter) has not discovered and matched the corresponding client-side DataReader (reply DataReader).

The above rules may be implemented outside “DDS layer” because no discovery algorithm modifications are required in the underlying DDS implementation to achieve “service discovery” beyond the extensions to the built-in topic data described in sub clause 7.6.2.1.

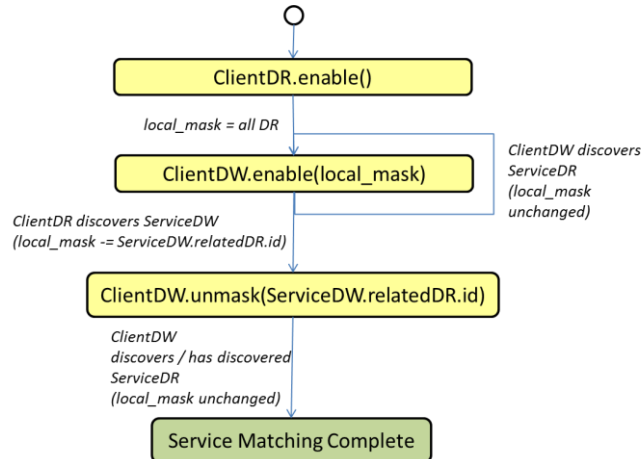

### 7.6.2.2.1 Client Matching

**Figure 43: The service-side client matching algorithm**

Figure 43 shows the client-matching algorithm executed at the service side. Client DataWriter and DataReader are discovered on the service-side using regular DDS discovery but “client matching” does not complete unless the service-side has discovered both client entities (DataReader and DataWriter). While “client matching” is still in progress, service-side does not process requests from the client. This behavior is illustrated in Figure 43 using a notional local state called `local_mask`. At the beginning, the service-side DataReader is enabled with `local_mask=All_DW` so that it does not process any the incoming requests. When the service-side DataWriter completes the discovery of a client DataReader, the service DataReader is ready to accept requests from that specific client. Therefore, it unmask the related client DataWriter. The “client matching” algorithm completes when the service-side has discovered both client DDS Entities.

### 7.6.2.2.2 Service Matching

**Figure 54: The client-side service matching algorithm**

Figure 54 shows the service-matching algorithm executed at the client side. Service DataWriter and DataReader are discovered using regular DDS discovery but “service matching” does not complete unless the client-side has discovered both service DDS Entities (DataReader and DataWriter) and it does not send requests to the service until “service matching” completes. This behavior is illustrated in Figure 54 using a notional local state called `local_mask`. At the beginning, the client-side DataWriter is enabled `local_mask=All_DR` such that it does not send any request at all. Attempts to send requests would be queued. When the client-side DataReader completes the discovery of a service DataWriter, the client DataWriter updates the local mask so that it can send requests to the service DataReader as long as it has been discovered. The “service matching” algorithm completes when the client-side has discovered both the service end-points.

## 7.7 Interface Evolution

### 7.7.1 Interface Evolution in the Basic Service Mapping

The Basic Service Profile has limited support for interface Evolution. I.e., the interfaces used by the client and the service may not match exactly. Interface evolution is constrained by the rules described herein.

#### 7.7.1.1 Adding/Removing an Operation

A client may use an interface that has fewer or more operations than what the service has implemented. If a client uses an interface that has fewer methods than that of the service, it is simply oblivious of the fact that the service has more capabilities than the client can use. If the client uses an interface with more operations than that of the service, invocation of an unimplemented-unsupported operation shall result in `REMOTE_EX_UNSUPPORTED` remote exception code.

### 7.7.1.2 Reordering Operations and Base Interfaces

Reordering operations has no impact on the semantics of the interface because every interface has set semantics. The order in which operations are listed in an interface is irrelevant to the caller. Reordering base interfaces has no impact on the semantics of the interface.

### 7.7.1.3 Changing Operation Signature

The Basic Service Profile shall not support any modifications to the operation signatures [including exception specification](#).

## 7.7.2 Interface Evolution in the Enhanced Service Mapping

The Enhanced Service Profile supports flexible interface evolution. It is possible for a client/service pair to use different interfaces where one interface is an evolution of the other. The client may be using an old interface and the service might be using the new interface or vice versa. Interface evolution is constrained by the rules described herein.

In sub clauses that follow,  $I_{old}$  represents the old interface whereas  $I_{new}$  represents the evolved interface. The interface mapping rules in the previous sub clause are designed such that the assignability rules defined in [DDS-XTypes] will ensure seamless evolution from  $I_{old}$  to  $I_{new}$ .

Each entity is in one of the four possible roles:  $C_{old}$ ,  $C_{new}$ ,  $S_{old}$ ,  $S_{new}$ .  $C_{old}$  is a client instance using an older version of the interface.  $C_{new}$  is a client instance using the new version of the interface. Likewise,  $S_{old}$  is the old version of service implementing the old interface whereas  $S_{new}$  is the new instance of the service implementing the new interface.

$C_{old}$  and  $S_{old}$  use the topic types synthesized from  $I_{old}$  whereas  $C_{new}$  and  $S_{new}$  use the topic types synthesized from  $I_{new}$ .  $Request_{old}$  and  $Reply_{old}$  are the types synthesized from  $I_{old}$  whereas  $Request_{new}$  and  $Reply_{new}$  are the types synthesized from  $I_{new}$ .

### 7.7.2.1 Adding a new Operation

Adding an operation to an interface will result in additional members in the synthesized topic types.  $C_{old}$  can invoke  $S_{new}$  because the additional member in  $Request_{new}$  is never populated by  $C_{old}$ .  $S_{new}$  responds with  $Reply_{new}$ , which remains assignable to  $Reply_{old}$  because the ids of members are based on md5 hash and therefore uniquely assignable to the target structure.

When  $C_{new}$  invokes  $S_{old}$ ,  $S_{old}$  receives a sample with no active member because the additional member in  $Request_{new}$  has no equivalent in  $Request_{old}$ . In such cases, the service ( $S_{old}$ ) returns  $Reply_{old}$  with `remoteEx = REMOTE_EX_UNKNOWN_OPERATION`. As the ids of the `remoteEx` member match in  $Reply_{old}$  and  $Reply_{new}$ , the sample is assignable and the  $C_{new}$  receives the correct remote exception code.

### 7.7.2.2 Removing an Operation

The case of removing an operation from an interface is quite analogous to adding an operation to an interface. When  $C_{old}$  calls  $S_{new}$ ,  $C_{old}$  receives `REMOTE_EX_UNKNOWN_OPERATION` `RemoteExceptionCode`. Likewise, When  $C_{new}$  invokes  $S_{old}$ ,  $C_{new}$  uses only a subset of operations supported by  $S_{old}$ .

### 7.7.2.3 Reordering Operations and Base Interfaces

Reordering operations has no impact on the semantics of the interface because every interface has set semantics. The order in which operations are listed in an interface is irrelevant to the caller. Due to the use of md5 hash algorithm to compute the member ids, this specification considers two interfaces equivalent as long they contain the same operations. Reordering base interfaces has no impact on the semantics of the interface.

### 7.7.2.4 Duck Typing Interface Evolution

Enhanced Service Profile supports “duck typing” evolution of an interface.

[**Non-Normative Note:** Duck typing is a style of dynamic typing in which an object's operations and properties determine the valid semantics, rather than its inheritance from a particular class or implementation of a specific interface. When two interfaces with the same name have the identical set of operations but in one interface all the operations are defined in-place whereas in the other interface one or more operations are inherited, the two (derived-most) interfaces are identical for the purpose of this specification. It is possible to specify the same topic name for two different interfaces. Therefore, as long as the topic names and type names match, the two interfaces are compatible.]

### 7.7.2.5 Changing Operation Signature

#### 7.7.2.5.1 Adding and Removing Parameters

Adding and removing parameters in an operation shall break compatibility with the older interface. The `@final` annotation on the *In* and *Out* structures enforce this restriction. It is, however, possible to mark an operation `@mutable` to allow the *In* and *Out* structures to be mutable and thereby supporting extensions.

#### 7.7.2.5.2 Reordering Parameters

Reordering parameters in an operation shall break compatibility with the older interface. The `@final` annotation on the *In* and *Out* structures enforce this restriction. It is, however, possible to mark an operation `@mutable` to allow reordering of parameters. In that case the synthesized structures (*In* and *Out*) shall be annotated `@mutable`.

#### 7.7.2.5.3 Changing the Type of a Parameters

Changing the type of the parameters is allowed by this specification. The type assignability rules shall be as described in [DDS-XTypes].

#### 7.7.2.5.4 Adding and Removing Return Type

Adding and removing return type shall break compatibility with the older interface. The `@final` annotation on the *In* and *Out* structures enforce this restriction. It is, however, possible to annotate an operation `@Mutable` to allow the *In* and *Out* structures to be mutable and consequently support addition or removal of return type and the interface level.

#### 7.7.2.5.5 Changing the Return Type

Changing the type of the return value is allowed by this specification. The type assignability rules shall be as described in [DDS-XTypes].

#### 7.7.2.5.6 Adding and Removing an Exception

This specification supports adding and removing one or more exceptions on an operation. The `@mutable` annotation on the return structure will support this interface evolution. The language binding that provides function call/return semantics may throw `REMOTE_EX_UNKNOWN_EXCEPTION` if the RPC call results into an exception that client does not understand.

### 7.8 Request and Reply Correlation

#### 7.8.1 Request and Reply Correlation in the Basic Service Profile

The Basic service profile uses the `RequestHeader` and `ReplyHeader` described in sub clause 7.5.1.1.1.

#### 7.8.2 Request and Reply Correlation in the Enhanced Service Profile

To support propagation of the sample identity of a related request this specification extends the [RTPS] specification adding a new parameter id `PID_RELATED_SAMPLE_IDENTITY` with value 0x0083. This parameter may appear in the `inlineQos` sub-message element of the `DATA` sub-message (see sub clause 9.4.5.3 in [RTPS]).

The `PID_RELATED_SAMPLE_IDENTITY` shall be used for data samples sent as reply to a request. When present, it shall contain the CDR serialization of the `SampleIdentity` structure defined below. The `RELATED_SAMPLE_IDENTITY_INVALID` constant is used to indicate an invalid/non-existing sample identity.

The value of the `PID_RELATED_SAMPLE_IDENTITY` in a reply message shall be identical to the sample identity (GUID, SN) of the request sample that triggered the reply.

[\[Issue DDSRPC -1: Clarifications and simple technical corrections\]](#)

```
struct SampleIdentity {  
    struct GUID_t writer_guid;  
    struct SequenceNumber_t sequence_number;  
}
```

`RELATED_SAMPLE_IDENTITY_INVALID` is defined as { `GUID_UNKNOWN` , `SEQUENCENUMBER_UNKNOWN` } both of which are defined in the [RTPS] specification.

#### 7.8.2.1 Retrieve the Request Identity at the Service Side

This specification provides language bindings ([section 7.11](#)) to retrieve the sample identity of the request in the form of a `SampleIdentity` object.

### 7.8.2.2 Retrieve the Request Identity at the Client Side

This specification provides language bindings ([section 7.11](#)) to retrieve the related sample identity of the reply from the reply `SampleInfo` in the form of a `SampleIdentity` object.

### 7.8.2.3 Propagating Request Sample Identity to the Client

Before sending a reply, the service implementation needs to set the related sample identity of the reply sample. The related sample identity is the same as the identity of the request sample. This specification provides language bindings to set the related sample identity when sending the reply to a request.

## 7.9 Service Lifecycle

### 7.9.1 Activating Services

In Basic and Enhanced Service Mappings, when using the function-call style language binding, creating an instance of the `Service` type activates the service. Likewise, when using the request/reply style language binding, creating an instance of a `Replier` activates the service.

Service activation shall result in creation of the underlying `DataReader` and `DataWriter` entities and they shall be enabled. An activated service shall be discoverable.

### 7.9.2 Processing Requests

#### 7.9.2.1 Processing Requests using Function-Call Style Language Binding

The function-call style language binding provides a synchronous way to receive requests and return replies. Concrete implementations of the interface operations shall be invoked as a consequence of receiving requests. The operations must return a reply consistent with the language binding.

#### 7.9.2.2 Processing Requests using Request/Reply Style Language Binding

The request/reply style language binding provides three mutually exclusive ways to process requests.

1. A synchronous service listener callback can be installed during service activation. The synchronous callback must return the reply before the callback returns. It is invoked for each received request.
2. An asynchronous service listener callback can be installed during service activation. The asynchronous callback does not return the reply. The callback receives a handle to the `Replier` instance and the `Replier` API can be used to retrieve the requests and send the replies. Unlike synchronous `Replier` listener callback, the asynchronous `Replier` listener allows decoupling of request reception from request processing.
3. The `Replier` API may be used to retrieve the requests and send replies.

### 7.9.3 Deactivating Services

Deleting (subject to language binding) the service instance deactivates the service. In Java language binding, `Closeable.close()` deactivates the service. In C++ language binding, the destructor of the service implementation shall deactivate the service. Deactivation shall delete the underlying DDS entities (i.e., `DataReader` and `DataWriter` only).

## 7.10 Service QoS

Both Basic and Enhanced Service Mappings allow QoS annotation with an interface.

### 7.10.1 Interface QoS Annotation

To set the specific QoS for an interface, the annotation @QoS shall be used. It is defined as follows.

```
@Annotation@annotation
local interface Qos
{
    attribute string RequestProfile;
    attribute string ReplyProfile;
};
```

**[Issue DDSRPC\_-25: QoS library name with profile filename]**

The profile attributes are string URLs of the form: <protocol>://path/resource where protocol, “:”, “/” and path are optional. Support for the [file://](#) protocol is mandatory. If the protocol:// is omitted, the string attributes are interpreted as if the protocol is [file://](#). **The URL may end with an optional library name. The profile filename and library name are separated by a #. For example, file://path/to/filename#library name.**

The QoS profiles are XML QoS Profiles as defined in the **[~~DDS-LWCCM~~DDS4CCM]** specification.

### 7.10.2 Default QoS

When no QoS is specified, default QoS are in effect. The default QoS for the endpoints (DataReaders and DataWriters) are specified as follows. The users may modify the mutable QoS policies at run-time.

QoS Policy	Value
Reliability	DDS_RELIABLE_RELIABILITY_QOS
History	DDS_KEEP_ALL_HISTORY_QOS
Durability	DDS_VOLATILE_DURABILITY_QOS

## 7.11 Language Bindings

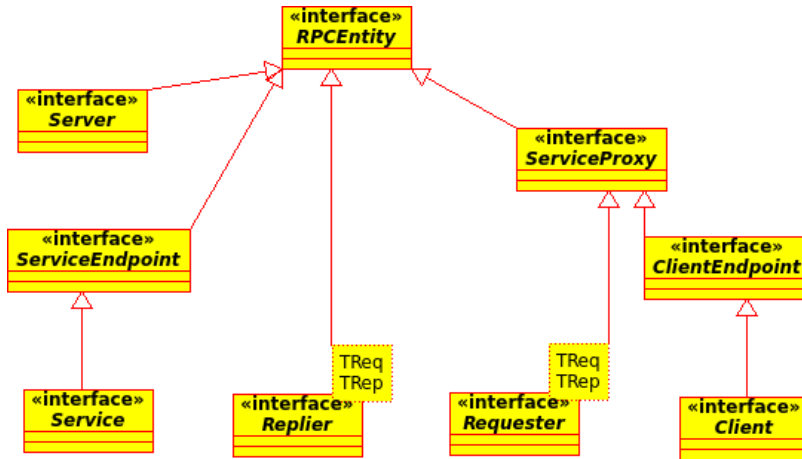

Figure 65: Inheritance Hierarchy of RPC Entities (TReq, TRep are type parameters)

### 7.11.1 C++ Language Binding

The normative language bindings for C++ is defined in [DDS RPC CXX Github]. Alternatively, and equivalently, the machine readable files associated with this specification represent the normative language bindings for C++. The following sub clause summarizes the normative reference.

#### 7.11.1.1 General C++ Language Binding Rules for Basic Service Mappings

##### 7.11.1.1.1 Request-Reply Style Language Binding

The request-reply style language binding for the Basic Service Mapping shall use either the user-defined IDL structs directly or the structs synthesized from an IDL interface. The IDL shall be mapped to C++ types as defined in [IDL35] (including the vendor-specific mappings for DDS v1.3). The Requester, Replier, Sample, SampleRef, WriteSample, and WriteSampleRef templates provide a uniform interface to send, receive, allocate, initialize, and destroy data.

##### 7.11.1.1.2 Function-Call Style Language Binding

The function-call style language binding for the Basic Service Mapping shall use the structs (and unions) synthesized from the user-defined IDL interface as specified in sub clause 7.5. The topic-types shall be mapped to C++ types as per defined in [DDS-Cxx-PSM] with the following additional rules.

1. Each IDL interface shall maps to an abstract class named “ $\${interface}$ ” and an abstract class named “ $\${interface}Async$ ” in the same namespace corresponding to the module of the interface. If there is no module, no C++ namespace is generated.

2. Both “`{interface}`” and “`{interface}Async`” abstract classes shall have a public virtual destructor.
3. Both “`{interface}`” and “`{interface}Async`” abstract classes shall have public `SupportType`, `RequestType`, and `ReplyType` typedefs for “`{interface}Support`”, “`{interface}_Request`”, and “`{interface}_Reply`” types.
4. The “`{interface}`” abstract class shall contain a public `AsyncInterfaceType` typedef for “`{interface}Async`”.
5. The “`{interface}Async`” abstract class shall contain a public `InterfaceType` typedef for “`{interface}`”.
6. The “`{interface}`” abstract class shall contain public pure virtual functions for all the operations and attributes defined in the IDL using the following rules
  - a. The name of the function shall be same as the name of the IDL operation.
  - b. The number and the order of the arguments shall be as defined in the IDL.
  - c. The functions shall not have any exception specification even if the IDL operation has an exception specification. The implementation may still throw the exceptions specified by the IDL operation.
  - d. The mapping of IDL primitive and container types to C++ types is provided in sub clause 7.4.2 in [DDS-Cxx-PSM].
  - e. The mapping of *In*, *Out*, and *InOut* primitive and constructed types (e.g., `struct`) is provided in in sub clause 7.4.5 in [DDS-Cxx-PSM].
  - f. Getter/Setter functions for attributes in an interface is specified in sub clause 7.4.6 in [DDS-Cxx-PSM].
  - g. IDL operations that return primitive types and enumeration types the corresponding C++ function shall return the C++ type by value as per the mapping specified in sub clause 7.4.2. in [DDS-Cxx-PSM].
  - h. IDL operations that return constructed type (e.g., `struct`) shall map to the first parameter with name “`cxx_return`” of type `T&` to the function and the function shall return `void`.
7. The “`{interface}Async`” abstract class shall contain asynchronous public pure virtual functions for all the operations and attributes defined in the IDL using the following rules
  - a. The name of the function shall be “`{operation}_async`”.
  - b. The function shall accept only *In* and *InOut* parameters and shall have no *Out* parameters.
  - c. The functions shall not have any exception specification even if the IDL operation has an exception specification.

- d. The mapping of IDL primitive and container types to C++ types is provided in sub clause 7.4.2 in [DDS-Cxx-PSM]. All the arguments shall be `const`.
  - e. The mapping of *In* and *InOut* primitive and constructed types (e.g., `struct`) is provided in in sub clause 7.4.5 in [DDS-Cxx-PSM]. All the arguments shall be `const`.
  - f. Attribute getter functions shall take no parameters and shall return `dds::rpc::future` of the same type as the attribute.
  - g. Attribute setter functions shall take a parameter as per specified in sub clause 7.4.6 in [DDS-Cxx-PSM]. It shall return a `dds::rpc::future<void>`.
  - h. Operation that produce a return value in the form of a regular return (primitive or constructed type) shall return a value of `dds::rpc::future` of that type.
  - i. Operation that produce return values with one or more *Out/InOut* parameters shall return a value of `dds::rpc::future` of “`{interface}_{operation}_Out`” type. Otherwise, it will return `dds::rpc::future<void>`.
8. Any identifier (e.g., parameter, operation name, exception, interface, module) in an IDL file that is a reserved word in C++ shall be prefixed by “`cxx_`”.

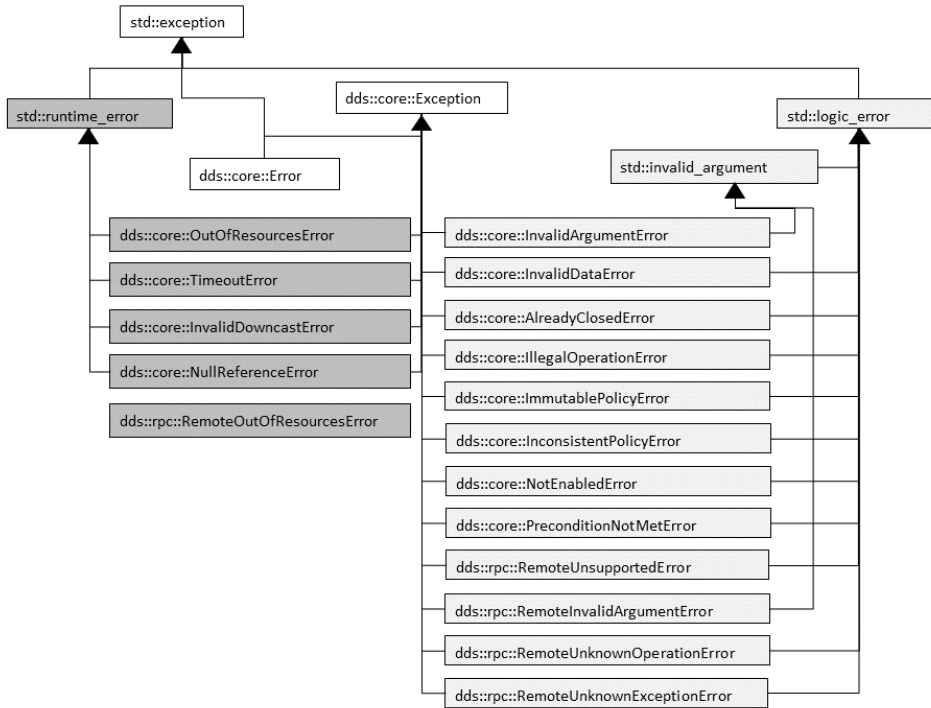

#### 7.11.1.2 General C++ Language Binding Rules for Enhanced Service Mappings

The request-reply style language binding for the Enhanced Service Mapping shall use either the user-defined IDL `structs` directly or the `structs` synthesized from an IDL interface. The IDL shall be mapped to C++ types as defined in [DDS-Cxx-PSM].

The function-call style language binding for the Enhanced Service Mapping shall use the mapping rules defined in sub clause 7.11.1.1.2.

#### 7.11.1.3 Mapping of Exceptions

The C++ language binding may throw locally generated and remotely generated exceptions. As such, all DDS exceptions defined in sub clause 7.5.5 in [DDS-Cxx-PSM] are valid exceptions. Additionally, remote exception codes defined in sub clause 7.5.2 are mapped to C++ exceptions as follows.

**Figure 76: Inheritance Hierarchy of Local and Remote Exceptions**

Specifically, the remote exception codes map to C++ exceptions as per the following table.

Remote Exception Code	RPC Exception
REMOTE_EX_OK	No exception
REMOTE_EX_UNSUPPORTED	dds::rpc::RemoteUnsupportedError
REMOTE_EX_INVALID_ARGUMENT	dds::rpc::RemoteInvalidArgumentError
REMOTE_EX_OUT_OF_RESOURCES	dds::rpc::RemoteOutOfResourcesError
REMOTE_EX_UNKNOWN_OPERATION	dds::rpc::RemoteUnknownOperationError
REMOTE_EX_UNKNOWN_EXCEPTION	dds::rpc::RemoteUnknownExceptionError

## 7.11.1.4 Summary of C++ Request-Reply Style Language Binding

### 7.11.1.4.1 Namespaces

The `dds`, and `dds::rpc` namespaces define the classes and functions for the request-reply style language bindings. Specifically, the language binding includes `RPCEntity`, `Requester`, `Replier`, `ServiceProxy`, `ListenerBase`, `SimpleReplierListener`, `ReplierListener`, `SimpleRequesterListener`, `RequesterListener`, `RequesterParams`, `ReplierParams`, `future`, `shared_future`, `Sample`, `SampleRef`, `WriteSample`, `WriteSampleRef`, `LoanedSamples`, `SharedSamples`, `SampleIterator`, `dds_type_traits`, and `dds_entity_traits`.

C++ request-reply language binding uses templates. Unless otherwise stated in the following sub clause, `TReq` represents the top-level request type and the `TRep` represents the top-level reply type. Depending upon the profile in use (Basic/Enhanced), the actual structure of the `TReq` and `TRep` types will vary. However, the request-reply language binding is independent of the profile in use.

### 7.11.1.4.2 RPCEntity

`RPCEntity` is the base abstract class extended by all the active RPC entities. It supports `close()` and `is_null()` operations.

### 7.11.1.4.3 Requester<TReq, TRep>

A requester sends requests and receives replies. `Requester` is a reference type and when copied it makes a shallow copy. An instance of a `Requester` is configured at the time of construction using `RequesterParams`, which is a container of configuration parameters, such as domain participant, QoS, listeners and more.

`Requester` is inherently asynchronous as sending a request and receiving its corresponding reply (or replies) are separated. `Requester` allows listener-based, polling-based, and future-based reception of replies. `SimpleRequesterListener` and `RequesterListener` interfaces enable callback-based notification when a reply is available. On the other hand, `Requester` provides functions to allow polling reception of replies. Future-based notification of replies is analogous to callback-based notification, however, no request-reply correlation is necessary because every `future` represents a reply to a unique request.

A requester reference may be bound to a specific service instance. Requests sent through a bound requester reference shall be sent to the bound service instance only.

### 7.11.1.4.4 ServiceProxy

`ServiceProxy` class defines type-independent operations for `Requester` and the `Client`. For example, binding to a specific instance, waiting for an instance to discover, closing the service, and more. `ServiceProxy` shall not be instantiated directly.

### 7.11.1.4.5 Replier<TReq, TRep>

A replier receives requests and send replies. `Replier` is a reference type and it is inexpensive to copy (comparable to a pointer assignment). An instance of `Replier` is configured at the time of

construction using `ReplierParams`, which is a container of configuration parameters such as domain participant, QoS, listeners and more.

`Replier` allows listener-based and polling-based reception of requests.

`SimpleReplierListener` and `ReplierListener` interfaces enable call-back based notification when a request is available. On the other hand, `Replier` provides functions to allow polling reception of requests.

#### 7.11.1.4.6 **ListenerBase**

`ListenerBase` is a “marker” abstract base class, which all generic listener abstract classes inherit from. It defines no member functions.

#### 7.11.1.4.7 **SimpleReplierListener<TReq, TRep>**

`SimpleReplierListener<TReq, TRep>` is used to provide a synchronous request listener for a `Replier`. `ReplierParams` is used to pass an instance of `SimpleReplierListener<TReq, TRep>`. It extends the `ListenerBase` abstract class and enables synchronous processing of the requests. I.e., the callback provides the request object and expects the reply as the return value.

#### 7.11.1.4.8 **ReplierListener<TReq, TRep>**

`ReplierListener<TReq, TRep>` interface is used to provide an asynchronous request listener for a `Replier`. It is passed to the `Replier` constructor through `ReplierParams`. It extends `ListenerBase` interface and enables asynchronous processing of the requests. I.e., the callback provides the `Replier` object and returns void.

#### 7.11.1.4.9 **SimpleRequesterListener<TRep>**

`SimpleRequesterListener<TRep>` abstract class is used to receive notifications of arrival of replies. It is used to configure a `Requester` through `RequesterParams`. It extends `ListenerBase` and enables processing of replies. I.e., the callback provides access to the reply sample and returns void.

#### 7.11.1.4.10 **RequesterListener<TReq, TRep>**

`RequesterListener<TReq, TRep>` interface is used to receive notification of reply arrival. It is used to configure a `Requester` through `RequesterParams`. It extends `ListenerBase` and enables processing of replies. I.e., the callback provides the replier object and returns void.

#### 7.11.1.4.11 **RequesterParams**

`RequesterParams` is a valuetype that serves as a container of configuration parameters of a `Requester`. It is designed to mimic the named-parameters feature available in some programming languages, which improves readability.

#### 7.11.1.4.12 **ReplierParams**

`ReplierParams` is a valuetype that serves as a container of configuration parameters of a `Replier`. It is designed to mimic the named-parameters feature available in some programming languages, which improves readability.

#### 7.11.1.4.13 **future<T>**

`future<T>` provides a mechanism to access the result of an asynchronous operation. It transports results (including exceptions) across an asynchronous boundary. In C++11 and C++14 environments, `dds::rpc::future<T>` is a typedef for `std::future<T>`. Compiler prior to C++11, `dds::rpc::future<T>` shall provide the same API as `std::future<T>` in C++11. Future is not copyable but it is movable.

#### 7.11.1.4.14 **shared\_future<T>**

`shared_future<T>` is closely related to `future<T>` and the only difference is that `shared_future<T>` is copyable and movable.

#### 7.11.1.4.15 **Sample<T>**

`Sample<T>` is a valetype that combines a value of type `T` and a value of type `SampleInfo`. `Sample` is conceptually immutable.

#### 7.11.1.4.16 **SampleRef<T>**

`SampleRef<T>` is a reference type that combines a value of type `T` and a value of type `SampleInfo`. Copying `SampleRef<T>` makes a shall copy.

#### 7.11.1.4.17 **WriteSample<T>**

`WriteSample<T>` is a valetype that combines a value of type `T` and a value of type `dds::SampleIdentity`. The user populates the value of `T` and the middleware populates the value of `dds::SampleIdentity`. When a request is sent as a `WriteSample`, upon function return, the `WriteSample.identity()` uniquely identifies the request sent.

#### 7.11.1.4.18 **WriteSampleRef<T>**

`WriteSampleRef<T>` is a reference type, which groups a reference to `T` and a value of type `dds::SampleIdentity`. The user populates the value of `T` and the middleware populates the value of `dds::SampleIdentity`. When a request is sent as a `WriteSampleRef<T>`, upon function return, the `WriteSample.identity()` uniquely identifies the request sent.

#### 7.11.1.4.19 **LoanedSamples<T>**

`LoanedSamples<T>` is conceptually a container of loaned `Sample<T>` from the middleware. `LoanedSamples<T>` is not copyable but it is movable. `LoanedSamples<T>::value_type` is `SampleRef<T>`. Upon destruction, `LoanedSamples<T>` returns the loaned samples to the middleware.

#### 7.11.1.4.20 **SharedSamples<T>**

`SharedSamples<T>` is container that contains loaned samples from the middleware but the `SharedSamples<T>` object may be copied in the application space. All copies of a `SharedSamples<T>` refer to the same set of loaned samples. `SharedSamples<T>::value_type` is `SampleRef<T>`. Upon destruction of the last

`SharedSamples<T>`, the underlying loaned samples are returned to the middleware. Note that `SharedSamples<T>` can be obtained from `LoanedSample<T>` but not vice versa.

#### 7.11.1.4.21 `SampleIterator<T>`

`SampleIterator<T>` is a random-access iterator over `LoanedSamples<T>` and `SharedSamples<T>`. `SampleIterator<T>::value_type` is a `SampleRef<T>`.

#### 7.11.1.4.22 `dds_type_traits<T>`

`dds_type_traits<T>` is a collection of meta-functions that given a type `T`, provides commonly needed dependent types, such as a `DataReader` for `T`, `DataWriter` for `T`, `Sample<T>`, `LoanedSamples<T>`, etc. The primary use of `dds_type_traits` is to provide a consistent syntax to refer to the dependent types irrespective of the DDS C++ language binding.

#### 7.11.1.4.23 `dds_entity_traits`

`dds_entity_traits` abstracts over the DDS entity types and provides consistent syntax to get DDS entity types irrespective of the DDS C++ language bindings. (e.g., `DomainParticipant`, `Publisher`, `Subscriber`, `DataReaderQos`, and `DataWriterQos`)

### 7.11.1.5 Summary of C++ Function-Call Style Language Binding

`Service`, `ServiceEndpoint`, `Server`, `Client`, and `ClientEndpoint` classes are specific to the function-call style language binding and are described below.

#### 7.11.1.5.1 `Service`

`Service` is a reference type and accepts a reference to the service implementation. A `Service` instantiates the underlying DDS entities and makes the service discoverable. Every `Service` inherits from `ServiceEndpoint`. A `Service` may belong to only one `Server`.

#### 7.11.1.5.2 `ServiceEndpoint`

A `ServiceEndpoint` provides type-independent functions to manage a service (e.g., pause, resume, close, etc.) A `ServiceEndpoint` shall not be instantiated directly; it can be obtained from a `Service` object. `ServiceEndpoint` is a reference type.

#### 7.11.1.5.3 `Server`

A `Server` is a container of one or more `Services`. `Server.run()` function begins dispatching the requests to the `Service` implementation. `Server` is a reference type.

#### 7.11.1.5.4 `Client`

`Client` is a reference type and provides functions to invoke operations on a remote service synchronously and asynchronously. A `Client` instantiates the underlying DDS entities and makes them discoverable. Every `Client` inherits publicly from “`{interface}`”, “`{interface}Async`”, and `ClientEndpoint` (public virtual).

#### 7.11.1.5.5 ClientEndpoint

A `ClientEndpoint` provides functions to obtain the underlying DDS entities at the client side. `ClientEndpoint` inherits from `ServiceProxy`. A `ClientEndpoint` shall not be instantiated directly; it can be obtained from a `Client` object.

### 7.11.2 Java Language Binding

~~The normative language bindings for Java is defined in [DDS-RPC-Java-Github]. Alternatively, and equivalently, the~~ `The` machine readable files associated with this specification represent the normative language bindings for Java. The Java language binding shall use IDL type mapping as per [DDS-Java-PSM].

The following sub clauses describe the entities that are either different or not described in the C++ language bindings.

#### 7.11.2.1 Mapping of Exceptions

#### 7.11.2.2 Summary of Java Request-Reply Style Language Binding

##### 7.11.2.2.1 Packages

The `org.omg.dds`, and `org.omg.dds.rpc` packages define the interfaces for the request-reply style language binding. Specifically, the language binding includes `Requester`, `Replier`, `ServiceProxy`, `RPCEntity`, `RPCRuntime`, `SimpleReplierListener`, `ReplierListener`, `SimpleRequesterListener`, `RequesterListener`, `RequesterParams`, `ReplierParams`, `Future`, `FutureCompletionListener`, `Sample`, and `Sample.Iterator`.

##### 7.11.2.2.2 RPCEntity

`RPCEntity` is the base interface extended by all the active entities. It inherits from the `DDSObject` interface defined in [DDS-Java-PSM] and `java.io.Closeable`. Its purpose is to provide quick access to the `RPCRuntime` object.

##### 7.11.2.2.3 RPCRuntime

`RPCRuntime` is the only abstract class with placeholder implementation in the Java language binding. It extends `ServiceEnvironment` abstract class defined in [DDS-Java-PSM]. Its purpose is to provide access to the `RPCRuntime` singleton, which serves as a factory for all other entities.

##### 7.11.2.2.4 Future<T>

The `rpc.Future<T>` interface extends the `java.util.concurrent.Future<T>` interface and adds a single operation to specify a `FutureCompletionListener`.

##### 7.11.2.2.5 FutureCompletionListener<T>

The `FutureCompletionListener` allows callback notification when the corresponding future becomes ready.

#### 7.11.2.2.6 **Sample<T>**

The `rpc.Sample<T>` interface extends `dds.sub.Sample<T>` interface and defines two additional operations to retrieve the `SampleIdentity` and the related sample identity, if any.

#### 7.11.2.2.7 **Sample.Iterator**

The `Sample.Iterator` interface is the same as in [DDS-Java-PSM].

### 7.11.2.3 **Summary of Java Function-Call Style Language Binding**

Function-Call style language binding in Java shall define the same entities as that of C++. See sub clause 7.11.1.5.

#### ~~7.11.3 **Non-normative Examples**~~

~~See `robot_reqrep.cxx` and `robot_func.cxx` in [DDS-RPC-CXX-Github] for C++.~~

~~See `test_robot.java` in [DDS-RPC-Java-Github] for Java.~~
