USE OF SPECIFICATION - TERMS, CONDITIONS & NOTICES

The material in this document details an Object Management Group specification in accordance with the terms, conditions and notices set forth below. This document does not represent a commitment to implement any portion of this specification in any company's products. The information contained in this document is subject to change without notice.

LICENSES

The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

Subject to all of the terms and conditions below, the owners of the copyright in this specification hereby grant you a fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use this specification to create and distribute software and special purpose specifications that are based upon this specification, and to use, copy, and distribute this specification as provided under the Copyright Act; provided that: (1) both the copyright notice identified above and this permission notice appear on any copies of this specification; (2) the use of the specifications is for informational purposes and will not be copied or posted on any network computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3) no modifications are made to this specification. This limited permission automatically terminates without notice if you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the specifications in your possession or control.

PATENTS

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.

GENERAL USE RESTRICTIONS

Any unauthorized use of this specification may violate copyright laws, trademark laws, and communications regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved. No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic, electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems--without permission of the copyright owner.
DISCLAIMER OF WARRANTY

WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE OR USE. IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The entire risk as to the quality and performance of software developed using this specification is borne by you. This disclaimer of warranty constitutes an essential part of the license granted to you to use this specification.

RESTRICTED RIGHTS LEGEND

Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1) (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)(1) and (2) of the Commercial Computer Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as indicated above and may be contacted through the Object Management Group, 109 Highland Avenue, Needham, MA 02494, U.S.A.

TRADEMARKS

IMM®, MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are registered trademarks of the Object Management Group, Inc., and Object Management Group™, OMG™, Unified Modeling Language™, Model Driven Architecture Logo™, Model Driven Architecture Diagram™, CORBA logos™, XMI Logo™, CWM™, CWM Logo™, MOF™, MOF™, OMG Interface Definition Language (IDL)™, and OMG SysML™ are trademarks of the Object Management Group. All other products or company names mentioned are used for identification purposes only, and may be trademarks of their respective owners.

COMPLIANCE

The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer software to use certification marks, trademarks or other special designations to indicate compliance with these materials. Software developed under the terms of this license may claim compliance or conformance with this specification if and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this specification, but may not claim compliance or conformance with this specification. In the event that testing suites are implemented or approved by Object Management Group, Inc., software developed using this specification may claim compliance or conformance with the specification only if the software satisfactorily completes the testing suites.
OMG’S ISSUE REPORTING PROCEDURE

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page http://www.omg.org, under Documents, Report a Bug/Issue (http://www.omg.org/report_issue.htm).

About the Object Management Group

OMG

Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer industry standards consortium that produces and maintains computer industry specifications for interoperable, portable and reusable enterprise applications in distributed, heterogeneous environments. Membership includes Information Technology vendors, end users, government agencies and academia.

OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle approach to enterprise integration that covers multiple operating systems, programming languages, middleware and networking infrastructures, and software development environments. OMG’s specifications include: UML® (Unified Modeling Language™); CORBA® (Common Object Request Broker Architecture); CWM™ (Common Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

More information on the OMG is available at http://www.omg.org/.

OMG Specifications

As noted, OMG specifications address middleware, modeling and vertical domain frameworks. All OMG Formal Specifications are available from this URL:

http://www.omg.org/spec

Specifications are organized by the following categories:

Business Modeling Specifications

Middleware Specifications

• CORBA/IIOP
• Data Distribution Services
• Specialized CORBA

IDL/Language Mapping Specifications

Modeling and Metadata Specifications

• UML, MOF, CWM, XMI
• UML Profile

Modernization Specifications
Platform Independent Model (PIM), Platform Specific Model (PSM), Interface Specifications

- CORBAServices
- CORBAFacilities

OMG Domain Specifications

CORBA Embedded Intelligence Specifications

CORBA Security Specifications

Signal and Image Processing

All of OMG’s formal specifications may be downloaded without charge from our website. (Products implementing OMG specifications are available from individual suppliers.) Copies of specifications, available in PostScript and PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management Group, Inc. at:

OMG Headquarters
109 Highland Avenue
Needham, MA 02494
USA
Tel: +1-781-444-0404
Fax: +1-781-444-0320
Email: pubs@omg.org

Certain OMG specifications are also available as ISO standards. Please consult http://www.iso.org

Issues

The reader is encouraged to report any technical or editing issues/problems with this specification to http://www.omg.org/report_issue.htm.
1 Overview

1.1 Introduction

The DDS specification describes a Data-Centric Publish-Subscribe (DCPS) model for distributed application communication and integration. This specification defines both the Application Interfaces (APIs) and the Communication Semantics (behavior and quality of service) that enable the efficient delivery of information from information producers to matching consumers.

- The purpose of the DDS specification can be summarized as enabling the “Efficient and Robust Delivery of the Right Information to the Right Place at the Right Time.”

The expected application domains require DCPS to be high-performance and predictable as well as efficient in its use of resources. To meet these requirements it is important that the interfaces are designed in such a way that they:

- Allow the middleware to pre-allocate resources so that dynamic resource allocation can be reduced to the minimum,
- Avoid properties that may require the use of unbounded or hard-to-predict resources, and
- Minimize the need to make copies of the data.

DDS uses typed interfaces (i.e., interfaces that take into account the actual data types) to the extent possible. Typed interfaces offer the following advantages:

- They are simpler to use: the programmer directly manipulates constructs that naturally represent the data.
- They are safer to use: verifications can be performed at compile time.
- They can be more efficient: the execution code can rely on the knowledge of the exact data type it has in advance, to e.g., pre-allocate resources.

It should be noted that the decision to use typed interfaces implies the need for a generation tool to translate type descriptions into appropriate interfaces and implementations that fill the gap between the typed interfaces and the generic middleware.

QoS (Quality of Service) is a general concept that is used to specify the behavior of a service. Programming service behavior by means of QoS settings offers the advantage that the application developer only indicates ‘what’ is wanted rather than ‘how’ this QoS should be achieved. Generally speaking, QoS is comprised of several QoS policies. Each QoS policy is then an independent description that associates a name with a value. Describing QoS by means of a list of independent QoS policies gives rise to more flexibility.

This specification is designed to allow a clear separation between the publish and the subscribe sides, so that an application process that only participates as a publisher can embed just what strictly relates to publication. Similarly, an application process that participates only as a subscriber can embed only what strictly relates to subscription.

1.2 Purpose

Many real-time applications have a requirement to model some of their communication patterns as a pure data-centric exchange, where applications publish (supply or stream) “data” which is then available to the remote applications that are interested in it. Relevant real-time applications can be found in C4I, industrial automation, distributed control and simulation, telecom equipment control, sensor networks, and network management systems. More generally, any application requiring (selective) information dissemination is a candidate for a data-driven network architecture.

Predictable distribution of data with minimal overhead is of primary concern to these real-time applications. Since it is not feasible to infinitely extend the needed resources, it is important to be able to specify the available resources and provide
policies that allow the middleware to align the resources to the most critical requirements. This necessity translates into the ability to control Quality of Service (QoS) properties that affect predictability, overhead, and resource utilization.

The need to scale to hundreds or thousands of publishers and subscribers in a robust manner is also an important requirement. This is actually not only a requirement of scalability but also a requirement of flexibility: on many of these systems, applications are added with no need/possibility to reconstruct the whole system. Data-centric communications decouples senders from receivers; the less coupled the publishers and the subscribers are, the easier these extensions become.

Distributed shared memory is a classic model that provides data-centric exchanges. However, this model is difficult to implement efficiently over a network and does not offer the required scalability and flexibility. Therefore, another model, the Data-Centric Publish-Subscribe (DCPS) model, has become popular in many real-time applications. This model builds on the concept of a “global data space” that is accessible to all interested applications. Applications that want to contribute information to this data space declare their intent to become “Publishers.” Similarly, applications that want to access portions of this data space declare their intent to become “Subscribers.” Each time a Publisher posts new data into this “global data space,” the middleware propagates the information to all interested Subscribers.

Underlying any data-centric publish subscribe system is a data model. This model defines the “global data space” and specifies how Publishers and Subscribers refer to portions of this space. The data-model can be as simple as a set of unrelated data-structures, each identified by a topic and a type. The topic provides an identifier that uniquely identifies some data items within the global data space1. The type provides structural information needed to tell the middleware how to manipulate the data and also allows the middleware to provide a level of type safety. However, the target applications often require a higher-level data model that allows expression of aggregation and coherence relationships among data elements.

Prior to the adoption of the DDS specification there were commercially available products that implemented many of these features (among them, NDDS from Real-Time Innovations and Splice from THALES Naval Nederland); however, these products were proprietary and did not offer standardized interfaces and behaviors. The purpose of the DDS specification is to define the standardized interfaces and behaviors that enable application portability. Since DDS’ adoption, at least ten compliant implementations have been developed. See http://portals.omg.org/dds/category/web-links/vendors.

This specification focuses on the portability of applications using the Data-Distribution Service. Wire-protocol interoperability between vendor implementations is covered in a different OMG specification: The Real-time Publish-Subscribe Wire Protocol DDS Interoperability Wire Protocol.”

---

1. In addition to topic and type, it is sometimes desirable for subscriptions to further refine the data they are interested in based on the content of the data itself. These so called content-based subscriptions are gaining popularity in large-scale systems.
2 Data-Centric Publish-Subscribe (DCPS)

2.1 Summary

This clause describes DCPS. DCPS defines the functionality used by an application to publish and subscribe to the values of data objects. It allows:

- Publishing applications to identify the data objects they intend to publish, and then provide values for these objects.
- Subscribing applications to identify which data objects they are interested in, and then access their data values.
- Applications to define topics, to attach type information to the topics, to create publisher and subscriber entities, to attach QoS policies to all these entities and, in summary, to make all these entities operate.

The description is organized into two sub clauses:

- The Platform Independent Model (PIM).
- The Platform Specific Model (PSM) for the OMG IDL platform based on the PIM.

2.2 Platform Independent Model (PIM)

2.2.1 Overview and Design Rationale

2.2.1.1 Format and Conventions

The purpose of this sub clause is to provide an operational overview of the DCPS PIM. To do so, it introduces many terms. Some of them are common terms whose meaning, in the context of publish-subscribe, is different from common usage. In cases where it is deemed appropriate, such terms will be italicized. Other terms are unique to publish-subscribe and/or to this specification, and are incorporated as key elements of the Class Model. The first time such terms are used, they will be formatted with Bold-italics. In this case, the written name is exactly the one of the corresponding class, which forbids the use of the plural. In case this would lead to ambiguity, it has been followed by ‘objects’ to state that there may not be only one of these.

In addition to the UML diagrams, all the classes that constitute the Service are documented using tables. The format used to document these classes is shown below.

---

1. In this case, the written name is exactly the one of the corresponding class, which forbids the use of the plural. In case this would lead to ambiguity, it has been followed by ‘objects’ to state that there may not be only one of these.
The operation `<parameter>` can contain the modifier “in,” “out,” or “inout” ahead of the parameter name. If this modifier is omitted, it is implied that the parameter is an “in” parameter.

In some cases the operation parameters or return value(s) are a collection with elements of a given `<type>`. This is indicated with the notation “<type> [ ].” This notation does not imply that it will be implemented as an array. The actual implementation is defined by the PSM: it may end up being mapped to a sequence, a list, or other kind of collection.

For example, the class named ‘MyClass’ below has a single attribute, named ‘my_attribute’ of type ‘long’ and a single operation ‘my_operation’ that returns a long. The operation takes four parameters. The first, ‘param1,’ is an output parameter of type long; the second, ‘param2,’ an input-output parameter of type long; the third, ‘param3,’ is an input parameter (the “in” modifier is implied by omission) of type long; and the fourth, ‘param4,’ is also an input parameter of type collection of longs.²

```
<table>
<thead>
<tr>
<th>attributes</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>my_attribute</td>
<td>long</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>operations</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>my_operation</td>
<td>long</td>
</tr>
</tbody>
</table>

  out: param1      | long             |
  inout: param2    | long             |
  param3           | long             |
  in: param4       | long             |
```

At the PIM level we have modeled errors as operation return codes typed `ReturnCode_t`. Each PSM may map these to either return codes or exceptions. The complete list of return codes is indicated below.

2. That is, a collection where the type of each element is ‘long’.
Any operation with return type `ReturnCode_t` may return OK, ERROR, or ILLEGAL_OPERATION. Any operation that takes an input parameter may additionally return BAD_PARAMETER. Any operation on an object created from any of the factories may additionally return ALREADY_DELETED. Any operation that is stated as optional may additionally return UNSUPPORTED. The return codes OK, ERROR, ILLEGAL_OPERATION, ALREADY_DELETED, UNSUPPORTED, and BAD_PARAMETER are the standard return codes and the specification won’t mention them explicitly for each operation. Operations that may return any of the additional (non-standard) error codes above will state so explicitly.

It is an error for an application to use an Entity that has already been deleted by means of the corresponding delete operation on the factory. If an application does this, the result is unspecified and will depend on the implementation and the PSM. In the cases where the implementation can detect the use of a deleted entity, the operation should fail and return ALREADY_DELETED.

### 2.2.1.2 Conceptual Outline

#### 2.2.1.2.1 Overview
Figure 2.1 - Overview

Information flows with the aid of the following constructs: Publisher and DataWriter on the sending side; Subscriber andDataReader on the receiving side.

- A Publisher is an object responsible for data distribution. It may publish data of different data types. A DataWriter acts as a typed accessor to a publisher. The DataWriter is the object the application must use to communicate to a publisher the existence and value of data-objects of a given type. When data-object values have been communicated to the publisher through the appropriate data-writer, it is the publisher’s responsibility to perform the distribution (the publisher will do this according to its own QoS, or the QoS attached to the corresponding data-writer). A publication is defined by the association of a data-writer to a publisher. This association expresses the intent of the application to publish the data described by the data-writer in the context provided by the publisher.

- A Subscriber is an object responsible for receiving published data and making it available (according to the Subscriber’s QoS) to the receiving application. It may receive and dispatch data of different specified types. To access the received data, the application must use a typed DataReader attached to the subscriber. Thus, a subscription is defined by the association of a data-reader with a subscriber. This association expresses the intent of the application to subscribe to the data described by the data-reader in the context provided by the subscriber.

Topic objects conceptually fit between publications and subscriptions. Publications must be known in such a way that subscriptions can refer to them unambiguously. A Topic is meant to fulfill that purpose: it associates a name (unique in the domain), a data-type, and QoS related to the data itself. In addition to the topic QoS, the QoS of the DataWriter associated

---

3. All those constructs are local to the application part. Actually they play the role of proxies to the service.
4. 'typed' means that each DataWriter object is dedicated to one application data-type.
5. Broadly speaking, a domain represents the set of applications that are communicating with each other. This concept is defined more precisely in 2.2.1.2.2, Overall Conceptual Model and 2.2.2.2.1, DomainParticipant Class.
with that Topic and the QoS of the Publisher associated to the DataWriter control the behavior on the publisher’s side, while the corresponding Topic, DataReader, and Subscriber QoS control the behavior on the subscriber’s side.

When an application wishes to publish data of a given type, it must create a Publisher (or reuse an already created one) and a DataWriter with all the characteristics of the desired publication. Similarly, when an application wishes to receive data, it must create a Subscriber (or reuse an already created one) and a DataReader to define the subscription.

### 2.2.1.2.2 Overall Conceptual Model

The overall conceptual model is shown in Figure 2.2. Notice that all the main communication objects (the specializations of Entity) follow unified patterns of:

- Supporting QoS (made up of several QosPolicy); QoS provides a generic mechanism for the application to control the behavior of the Service and tailor it to its needs. Each Entity supports its own specialized kind of QoS policies. The complete list of QoS policies and their meaning is described in 2.2.3, Supported QoS.

- Accepting a Listener; listeners provide a generic mechanism for the middleware to notify the application of relevant asynchronous events, such as arrival of data corresponding to a subscription, violation of a QoS setting, etc. Each DCPS entity supports its own specialized kind of listener. Listeners are related to changes in status conditions. This relationship is described in 2.2.4, Listeners, Conditions, and Wait-sets.

- Accepting a StatusCondition (and a set of ReadCondition objects for the DataReader); conditions (in conjunction with WaitSet objects) provide support for an alternate communication style between the middleware and the application (i.e., wait-based rather than notification-based). The complete set of status conditions is described in 2.2.4, Listeners, Conditions, and Wait-sets.

All these DCPS entities are attached to a DomainParticipant. A domain participant represents the local membership of the application in a domain. A domain is a distributed concept that links all the applications able to communicate with each other. It represents a communication plane: only the publishers and the subscribers attached to the same domain may interact.

**DomainEntity** is an intermediate object whose only purpose is to state that a DomainParticipant cannot contain other domain participants.

---

6. This specification made the choice of allowing the attachment of only one Listener per entity (instead of a list of them). The reason for that choice is that this allows a much simpler (and, thus, more efficient) implementation as far as the middleware is concerned. Moreover, if it were required, implementing a listener that, when triggered, triggers in return attached 'sub-listeners,' can be easily done by the application.
At the DCPS level, data types represent information that is sent atomically. By default, each data modification is propagated individually, independently, and uncorrelated with other modifications. However, an application may request that several modifications be sent as a whole and interpreted as such at the recipient side. This functionality is offered on a Publisher/Subscriber basis. That is, these relationships can only be specified among DataWriter objects attached to the same Publisher and retrieved among DataReader objects attached to the same Subscriber.

By definition, a Topic corresponds to a single data type. However, several topics may refer to the same data type. Therefore, a Topic identifies data of a single type, ranging from one single instance to a whole collection of instances of that given type. This is shown in Figure 2.3 for the hypothetical data-type “Foo.”

---

7. Note that the optional DLRL layer provides the means to break data-objects into separate elements, each sent atomically.
In case a set of instances is gathered under the same topic, different instances must be distinguishable. This is achieved by means of the values of some data fields that form the key to that data set. The key description (i.e., the list of data fields whose value forms the key) has to be indicated to the middleware. The rule is simple: different data values with the same key value represent successive values for the same instance, while different data values with different key values represent different instances. If no key is provided, the data set associated with the Topic is restricted to a single instance.

Topics need to be known by the middleware and potentially propagated. Topic objects are created using the create operations provided by DomainParticipant.

The interaction style is straightforward on the publisher’s side: when the application decides that it wants to make data available for publication, it calls the appropriate operation on the related DataWriter (this, in turn, will trigger its Publisher).

On the subscriber’s side however, there are more choices: relevant information may arrive when the application is busy doing something else or when the application is just waiting for that information. Therefore, depending on the way the application is designed, asynchronous notifications or synchronous access may be more appropriate. Both interaction modes are allowed, a Listener is used to provide a callback for synchronous access and a WaitSet associated with one or several Condition objects provides asynchronous data access.

The same synchronous and asynchronous interaction modes can also be used to access changes that affect the middleware communication status. For instance, this may occur when the middleware asynchronously detects an inconsistency. In addition, other middleware information that may be relevant to the application (such as the list of the existing topics) is made available by means of built-in topics that the application can access as plain application data, using built-in\(^8\) data-readers.

### 2.2.2 PIM Description

The DCPS is comprised of five modules:

---

8. These built-in data-readers should be provided with every implementation of the service. They are further described in 2.2.5, Built-in Topics.
Figure 2.4 - DCPS module breakdown

1. The Infrastructure Module defines the abstract classes and the interfaces that are refined by the other modules. It also provides support for the two interaction styles (notification- and wait- based) with the middleware.

2. The Domain Module contains the DomainParticipant class that acts as an entry-point of the Service and acts as a factory for many of the classes. The DomainParticipant also acts as a container for the other objects that make up the Service.

3. The Topic-Definition Module contains the Topic, ContentFilteredTopic, and MultiTopic classes, the TopicListener interface, and more generally, all that is needed by the application to define Topic objects and attach QoS policies to them.

4. The Publication Module contains the Publisher and DataWriter classes as well as the PublisherListener and DataWriterListener interfaces, and more generally, all that is needed on the publication side.

5. The Subscription Module contains the Subscriber, DataReader, ReadCondition, and QueryCondition classes, as well as the SubscriberListener and DataReaderListener interfaces, and more generally, all that is needed on the subscription side.

At the PIM level, we have chosen to model any entity as a class or interface. It should be noted, however, that this does not mean that any of them will be translated into an IDL interface. In general, we have chosen to model as interfaces the entities that the application will have to extend to interact with the Service. The remaining entities have been modeled as classes.
2.2.2.1 Infrastructure Module

The DCPS Infrastructure Module is comprised of the following classifiers:

- Entity
- DomainEntity
- QosPolicy
- Listener
- Status
- WaitSet
- Condition
- GuardCondition
- StatusCondition

2.2.2.1.1 Entity Class

This class is the abstract base class for all the DCPS objects that support QoS policies, a listener and a status condition.
**StatusKind** is an enumerated type that identifies each concrete *Status* type.

The following sub clauses explain all the operations in detail.

### 2.2.2.1.1 set_qos (abstract)

This operation is used to set the QoS policies of the *Entity*. This operation must be provided by each of the derived *Entity* classes (*DomainParticipant, Topic, Publisher, DataWriter, Subscriber, DataReader*) so that the policies that are meaningful to each *Entity* can be set.

The set of policies specified as the `qos_list` parameter are applied on top of the existing QoS, replacing the values of any policies previously set.

As described in 2.2.3, Supported QoS, certain policies are “immutable;” they can only be set at *Entity* creation time, or before the entity is made enabled. If `set_qos` is invoked after the *Entity* is enabled and it attempts to change the value of an “immutable” policy, the operation will fail and it returns IMMUTABLE_POLICY.

Sub clause 2.2.3, Supported QoS also describes that certain values of QoS policies can be incompatible with the settings of the other policies. The `set_qos` operation will also fail if it specifies a set of values that once combined with the existing values would result in an inconsistent set of policies. In this case, the return value is INCONSISTENT_POLICY.

If the application supplies a non-default value for a QoS policy that is not supported by the implementation of the service, the `set_qos` operation will fail and return UNSUPPORTED.

The existing set of policies are only changed if the `set_qos` operation succeeds. This is indicated by the OK return value. In all other cases, none of the policies is modified.

Each derived *Entity* class (*DomainParticipant, Topic, Publisher, DataWriter, Subscriber, DataReader*) has a corresponding special value of the QoS (PARTICIPANT_QOS_DEFAULT, PUBLISHER_QOS_DEFAULT, SUBSCRIBER_QOS_DEFAULT, TOPIC_QOS_DEFAULT, DATAWRITER_QOS_DEFAULT, DATAREADER_QOS_DEFAULT).
DATAREADER_QOS_DEFAULT). This special value may be used as a parameter to the set_qos operation to indicate that the QoS of the Entity should be changed to match the current default QoS set in the Entity’s factory. The operation set_qos cannot modify the immutable QoS so a successful return of the operation indicates that the mutable QoS for the Entity has been modified to match the current default for the Entity’s factory.

Possible error codes returned in addition to the standard ones: INCONSISTENT_POLICY, IMMUTABLE_POLICY.

2.2.2.1.1.2 get_qos (abstract)

This operation allows access to the existing set of QoS policies for the Entity. This operation must be provided by each of the derived Entity classes (DomainParticipant, Topic, Publisher, DataWriter, Subscriber, DataReader) so that the policies meaningful to the particular Entity are retrieved.

2.2.2.1.1.3 set_listener (abstract)

This operation installs a Listener on the Entity. The listener will only be invoked on the changes of communication status indicated by the specified mask.

It is permitted to use ‘nil’ as the value of the listener. The ‘nil’ listener behaves as a Listener whose operations perform no action.

Only one listener can be attached to each Entity. If a listener was already set, the operation set_listener will replace it with the new one. Consequently if the value ‘nil’ is passed for the listener parameter to the set_listener operation, any existing listener will be removed.

This operation must be provided by each of the derived Entity classes (DomainParticipant, Topic, Publisher, DataWriter, Subscriber, DataReader) so that the listener is of the concrete type suitable to the particular Entity.

2.2.2.1.1.4 get_listener (abstract)

This operation allows access to the existing Listener attached to the Entity.

This operation must be provided by each of the derived Entity classes (DomainParticipant, Topic, Publisher, DataWriter, Subscriber, DataReader) so that the listener is of the concrete type suitable to the particular Entity.

2.2.2.1.1.5 get_statuscondition

This operation allows access to the StatusCondition (2.2.1.9, StatusCondition Class) associated with the Entity. The returned condition can then be added to a WaitSet (2.2.1.6, WaitSet Class) so that the application can wait for specific status changes that affect the Entity.

2.2.2.1.1.6 get_status_changes

This operation retrieves the list of communication statuses in the Entity that are ‘triggered.’ That is, the list of statuses whose value has changed since the last time the application read the status. The precise definition of the ‘triggered’ state of communication statuses is given in 2.2.4.2, Changes in Status.

When the entity is first created or if the entity is not enabled, all communication statuses are in the “untriggered” state so the list returned by the get_status_changes operation will be empty.

The list of statuses returned by the get_status_changes operation refers to the status that are triggered on the Entity itself and does not include statuses that apply to contained entities.
2.2.2.1.1.7 enable

This operation enables the Entity. Entity objects can be created either enabled or disabled. This is controlled by the value of the ENTITY_FACTORY Qos policy (2.2.3.20, ENTITY_FACTORY) on the corresponding factory for the Entity.

The default setting of ENTITY_FACTORY is such that, by default, it is not necessary to explicitly call enable on newly created entities (see 2.2.3.20, ENTITY_FACTORY).

The enable operation is idempotent. Calling enable on an already enabled Entity returns OK and has no effect.

If an Entity has not yet been enabled, the following kinds of operations may be invoked on it:

- Operations to set or get an Entity’s QoS policies (including default QoS policies) and listener
- get_statuscondition
- ‘factory’ operations
- get_status_changes and other get status operations (although the status of a disabled entity never changes)
- ‘lookup’ operations

Other operations may explicitly state that they may be called on disabled entities; those that do not will return the error NOT_ENABLED.

It is legal to delete an Entity that has not been enabled by calling the proper operation on its factory.

Entities created from a factory that is disabled, are created disabled regardless of the setting of the ENTITY_FACTORY Qos policy.

Calling enable on an Entity whose factory is not enabled will fail and return PRECONDITION_NOT_MET.

If the ENTITY_FACTORY Qos policy has autoenable_created_entities set to TRUE, the enable operation on the factory will automatically enable all entities created from the factory.

The Listeners associated with an entity are not called until the entity is enabled. Conditions associated with an entity that is not enabled are “inactive,” that is, have a trigger_value==FALSE (see 2.2.4.4, Conditions and Wait-sets).

2.2.2.1.8 get_instance_handle

This operation returns the InstanceHandle_t that represents the Entity.

2.2.2.1.2 DomainEntity Class

DomainEntity is the abstract base class for all DCPS entities, except for the DomainParticipant. Its sole purpose is to express that DomainParticipant is a special kind of Entity, which acts as a container of all other Entity, but itself cannot contain other DomainParticipant.

<table>
<thead>
<tr>
<th>DomainEntity</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>no operations</td>
</tr>
</tbody>
</table>
2.2.2.1.3 QosPolicy Class

This class is the abstract root for all the QoS policies.

```
<table>
<thead>
<tr>
<th>QosPolicy</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
</tr>
<tr>
<td>name</td>
</tr>
<tr>
<td>string</td>
</tr>
<tr>
<td>no operations</td>
</tr>
</tbody>
</table>
```

It provides the basic mechanism for an application to specify quality of service parameters. It has an attribute `name` that is used to identify uniquely each QoS policy. All concrete `QosPolicy` classes derive from this root and include a `value` whose type depends on the concrete QoS policy.

The type of a `QosPolicy` value may be atomic, such as an integer or float, or compound (a structure). Compound types are used whenever multiple parameters must be set coherently to define a consistent value for a `QosPolicy`.

Each `Entity` can be configured with a list of `QosPolicy`. However, any `Entity` cannot support any `QosPolicy`. For instance, a `DomainParticipant` supports different `QosPolicy` than a `Topic` or a `Publisher`.

`QosPolicy` can be set when the `Entity` is created, or modified with the `set_qos` method. Each `QosPolicy` in the list is treated independently from the others. This approach has the advantage of being very extensible. However, there may be cases where several policies are in conflict. Consistency checking is performed each time the policies are modified via the `set_qos` operation.

When a policy is changed after being set to a given value, it is not required that the new value be applied instantaneously; the Service is allowed to apply it after a transition phase. In addition, some `QosPolicy` have “immutable” semantics meaning that they can only be specified either at `Entity` creation time or else prior to calling the `enable` operation on the `Entity`.

Sub clause 2.2.3, Supported QoS provides the list of all `QosPolicy`, their meaning, characteristics and possible values, as well as the concrete `Entity` to which they apply.

2.2.2.1.4 Listener Interface

`Listener` is the abstract root for all `Listener` interfaces. All the supported kinds of concrete `Listener` interfaces (one per concrete `Entity`: `DomainParticipant`, `Topic`, `Publisher`, `DataWriter`, `Subscriber`, and `DataReader`) derive from this root and add methods whose prototype depends on the concrete `Listener`.

```
<table>
<thead>
<tr>
<th>Listener</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>no operations</td>
</tr>
</tbody>
</table>
```

See 2.2.4.3, Access through Listeners for the list of defined listener interfaces. Listener interfaces provide a mechanism for the Service to asynchronously inform the application of relevant changes in the communication status.
2.2.2.1.5 Status Class

*Status* is the abstract root class for all communication status objects. All concrete kinds of *Status* classes specialize this class.

<table>
<thead>
<tr>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>no operations</td>
</tr>
</tbody>
</table>

Each concrete *Entity* is associated with a set of *Status* objects whose value represents the “communication status” of that entity. These status values can be accessed with corresponding methods on the *Entity*. The changes on these status values are the ones that both cause activation of the corresponding *StatusCondition* objects and trigger invocation of the proper *Listener* objects to asynchronously inform the application.

*Status* objects and their relationship to *Listener* and *Condition* objects are detailed in 2.2.4.1, Communication Status.

2.2.2.1.6 WaitSet Class

A *WaitSet* object allows an application to wait until one or more of the attached *Condition* objects has a *trigger_value* of *TRUE* or else until the timeout expires.

<table>
<thead>
<tr>
<th>WaitSet</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>attach_condition</td>
</tr>
<tr>
<td>a_condition</td>
</tr>
<tr>
<td>detach_condition</td>
</tr>
<tr>
<td>a_condition</td>
</tr>
<tr>
<td>wait</td>
</tr>
<tr>
<td>inout: active_conditions</td>
</tr>
<tr>
<td>timeout</td>
</tr>
<tr>
<td>get_conditions</td>
</tr>
<tr>
<td>inout: attached_conditions</td>
</tr>
</tbody>
</table>

*WaitSet* has no factory. It is created as an object directly by the natural means in each language binding (e.g., using “new” in C++ or Java). This is because it is not necessarily associated with a single *DomainParticipant* and could be used to wait on *Condition* objects associated with different *DomainParticipant* objects.

The following sub clauses explain all the operations in detail.

2.2.2.1.6.1 attach_condition

Attaches a *Condition* to the *WaitSet*.

It is possible to attach a *Condition* on a *WaitSet* that is currently being waited upon (via the *wait* operation). In this case, if the *Condition* has a *trigger_value* of *TRUE*, then attaching the condition will unblock the *WaitSet*. 
Adding a *Condition* that is already attached to the *WaitSet* has no effect.

Possible error codes returned in addition to the standard ones: OUT_OF_RESOURCES.

**2.2.2.1.6.2 detach_condition**

Detaches a *Condition* from the *WaitSet*.

If the *Condition* was not attached to the *WaitSet*, the operation will return PRECONDITION_NOT_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

**2.2.2.1.6.3 wait**

This operation allows an application thread to wait for the occurrence of certain conditions. If none of the conditions attached to the *WaitSet* have a *trigger_value* of TRUE, the wait operation will block suspending the calling thread.

The result of the *wait* operation is the list of all the attached conditions that have a *trigger_value* of TRUE (i.e., the conditions that unblocked the wait).

The wait operation takes a *timeout* argument that specifies the maximum duration for the wait. If this duration is exceeded and none of the attached *Condition* objects is true, *wait* will return with the return code TIMEOUT.

It is not allowed for more than one application thread to be waiting on the same *WaitSet*. If the *wait* operation is invoked on a *WaitSet* that already has a thread blocking on it, the operation will return immediately with the value PRECONDITION_NOT_MET.

**2.2.2.1.6.4 get_conditions**

This operation retrieves the list of attached conditions.

**2.2.2.1.7 Condition Class**

A *Condition* is a root class for all the conditions that may be attached to a *WaitSet*. This basic class is specialized in three classes that are known by the middleware: *GuardCondition* (2.2.2.1.8), *StatusCondition* (2.2.2.1.9), and *ReadCondition* (2.2.2.5.8).

<table>
<thead>
<tr>
<th><em>Condition</em></th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>get_trigger_value</td>
</tr>
</tbody>
</table>

A *Condition* has a *trigger_value* that can be TRUE or FALSE and is set automatically by the Service.

**2.2.2.1.7.1 get_trigger_value**

This operation retrieves the *trigger_value* of the *Condition*. 
2.2.2.1.8 GuardCondition Class

A GuardCondition object is a specific Condition whose trigger_value is completely under the control of the application.

<table>
<thead>
<tr>
<th>GuardCondition</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>set_trigger_value</td>
</tr>
<tr>
<td>value</td>
</tr>
</tbody>
</table>

GuardCondition has no factory. It is created as an object directly by the natural means in each language binding (e.g., using “new” in C++ or Java. When first created the trigger_value is set to FALSE.

The purpose of the GuardCondition is to provide the means for the application to manually wakeup a WaitSet. This is accomplished by attaching the GuardCondition to the WaitSet and then setting the trigger_value by means of the set_trigger_value operation.

2.2.2.1.8.1 set_trigger_value

This operation sets the trigger_value of the GuardCondition.

WaitSet objects behavior depends on the changes of the trigger_value of their attached conditions. Therefore, any WaitSet to which is attached the GuardCondition is potentially affected by this operation.

2.2.2.1.9 StatusCondition Class

A StatusCondition object is a specific Condition that is associated with each Entity.

<table>
<thead>
<tr>
<th>StatusCondition</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>set_enabled_statuses</td>
</tr>
<tr>
<td>mask</td>
</tr>
<tr>
<td>get_enabled_statuses</td>
</tr>
<tr>
<td>get_entity</td>
</tr>
</tbody>
</table>

The trigger_value of the StatusCondition depends on the communication status of that entity (e.g., arrival of data, loss of information, etc.), ‘filtered’ by the set of enabled_statuses on the StatusCondition.

The enabled_statuses and its relation to Listener and WaitSet is detailed in 2.2.4.4.1, Trigger State of the StatusCondition.

2.2.2.1.9.1 set_enabled_statuses

This operation defines the list of communication statuses that are taken into account to determine the trigger_value of the StatusCondition. This operation may change the trigger_value of the StatusCondition.
*WaitSet* objects behavior depend on the changes of the *trigger_value* of their attached conditions. Therefore, any *WaitSet* to which the *StatusCondition* is attached is potentially affected by this operation.

If this function is not invoked, the default list of enabled statuses includes all the statuses.

### 2.2.2.1.9.2 get_enabled_statuses

This operation retrieves the list of communication statuses that are taken into account to determine the *trigger_value* of the *StatusCondition*. This operation returns the statuses that were explicitly set on the last call to *set_enabled_statuses* or, if *set_enabled_statuses* was never called, the default list (see 2.2.2.1.9.1).

### 2.2.2.1.9.3 get_entity

This operation returns the *Entity* associated with the *StatusCondition*. Note that there is exactly one *Entity* associated with each *StatusCondition*. 

---

*Data Distribution Service, v1.4*
2.2.2.2 Domain Module

The DCPS Domain Module is comprised of the following classes:

- DomainParticipant
- DomainParticipantFactory
- DomainParticipantListener

2.2.2.2.1 DomainParticipant Class

The DomainParticipant object plays several roles:

- It acts as a container for all other Entity objects.
- It acts as factory for the Publisher, Subscriber, Topic, and MultiTopic Entity objects.
• It represents the participation of the application on a communication plane that isolates applications running on the same set of physical computers from each other. A domain establishes a “virtual network” linking all applications that share the same domainId and isolating them from applications running on different domains. In this way, several independent distributed applications can coexist in the same physical network without interfering, or even being aware of each other.

• It provides administration services in the domain, offering operations that allow the application to ‘ignore’ locally any information about a given participant (ignore_participant), publication (ignore_publication), subscription (ignore_subscription), or topic (ignore_topic).

<table>
<thead>
<tr>
<th>DomainParticipant</th>
</tr>
</thead>
<tbody>
<tr>

<td>qos_list</td>
</tr>
</tbody>
</table>
The following sub clauses explain all the operations in detail.

The following operations may be called even if the **DomainParticipant** is not enabled. Other operations will have the value **NOT_ENABLED** if called on a disabled **DomainParticipant**:

- Operations defined at the base-class level namely, `set_qos`, `get_qos`, `set_listener`, `get_listener`, and `enable`.
- Factory methods: `create_topic`, `create_publisher`, `create_subscriber`, `delete_topic`, `delete_publisher`, `delete_subscriber`
- Operations that access the status: `get_statuscondition`

### 2.2.2.1.1 `create_publisher`

This operation creates a **Publisher** with the desired QoS policies and attaches to it the specified **PublisherListener**.

If the specified QoS policies are not consistent, the operation will fail and no **Publisher** will be created.

The special value `PUBLISHER_QOS_DEFAULT` can be used to indicate that the **Publisher** should be created with the default Publisher QoS set in the factory. The use of this value is equivalent to the application obtaining the default **Publisher** QoS by means of the operation `get_default_publisher_qos` (2.2.2.1.21) and using the resulting QoS to create the **Publisher**.

The created **Publisher** belongs to the **DomainParticipant** that is its factory.
In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

### 2.2.2.2.1.2 delete_publisher

This operation deletes an existing Publisher.

A Publisher cannot be deleted if it has any attached DataWriter objects. If delete_publisher is called on a Publisher with existing DataWriter object, it will return PRECONDITION\_NOT\_MET.

The delete_publisher operation must be called on the same DomainParticipant object used to create the Publisher. If delete_publisher is called on a different DomainParticipant, the operation will have no effect and it will return PRECONDITION\_NOT\_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION\_NOT\_MET.

### 2.2.2.2.1.3 create_subscriber

This operation creates a Subscriber with the desired QoS policies and attaches to it the specified SubscriberListener.

If the specified QoS policies are not consistent, the operation will fail and no Subscriber will be created.

The special value SUBSCRIBER\_QOS\_DEFAULT can be used to indicate that the Subscriber should be created with the default Subscriber QoS set in the factory. The use of this value is equivalent to the application obtaining the default Subscriber QoS by means of the operation get_default_subscriber_qos (2.2.2.1.21) and using the resulting QoS to create the Subscriber.

The created Subscriber belongs to the DomainParticipant that is its factory.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

### 2.2.2.2.1.4 delete_subscriber

This operation deletes an existing Subscriber.

A Subscriber cannot be deleted if it has any attached DataReader objects. If the delete_subscriber operation is called on a Subscriber with existing DataReader objects, it will return PRECONDITION\_NOT\_MET.

The delete_subscriber operation must be called on the same DomainParticipant object used to create the Subscriber. If delete_subscriber is called on a different DomainParticipant, the operation will have no effect and it will return PRECONDITION\_NOT\_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION\_NOT\_MET.

### 2.2.2.2.1.5 create_topic

This operation creates a Topic with the desired QoS policies and attaches to it the specified TopicListener.

If the specified QoS policies are not consistent, the operation will fail and no Topic will be created.

The special value TOPIC\_QOS\_DEFAULT can be used to indicate that the Topic should be created with the default Topic QoS set in the factory. The use of this value is equivalent to the application obtaining the default Topic QoS by means of the operation get_default_topic_qos (2.2.2.1.21) and using the resulting QoS to create the Topic.

The created Topic belongs to the DomainParticipant that is its factory.
The \textit{Topic} is bound to a type described by the \texttt{type_name} argument. Prior to creating a \textit{Topic} the type must have been registered with the Service. This is done using the \texttt{register_type} operation on a derived class of the \texttt{TypeSupport} interface as described in 2.2.2.3.6, TypeSupport Interface.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

\textbf{2.2.2.1.6 delete_topic}

This operation deletes a \textit{Topic}.

The deletion of a \textit{Topic} is not allowed if there are any existing \texttt{DataReader}, \texttt{DataWriter}, \texttt{ContentFilteredTopic}, or \texttt{MultiTopic} objects that are using the \textit{Topic}. If the \texttt{delete_topic} operation is called on a \textit{Topic} with any of these existing objects attached to it, it will return PRECONDITION\_NOT\_MET.

The \texttt{delete_topic} operation must be called on the same \texttt{DomainParticipant} object used to create the \textit{Topic}. If \texttt{delete_topic} is called on a different \texttt{DomainParticipant}, the operation will have no effect and it will return PRECONDITION\_NOT\_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION\_NOT\_MET.

\textbf{2.2.2.1.7 create_contentfilteredtopic}

This operation creates a \texttt{ContentFilteredTopic}. As described in 2.2.2.3, Topic-Definition Module, a \texttt{ContentFilteredTopic} can be used to do content-based subscriptions.

The related \textit{Topic} being subscribed to is specified by means of the \texttt{related_topic} parameter. The \texttt{ContentFilteredTopic} only relates to samples published under that \textit{Topic}, filtered according to their content. The filtering is done by means of evaluating a logical expression that involves the values of some of the data-fields in the sample. The logical expression is derived from the \texttt{filter_expression} and \texttt{expression_parameters} arguments.

The syntax of the filter expression and parameters is described in Annex B.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

\textbf{2.2.2.1.8 delete_contentfilteredtopic}

This operation deletes a \texttt{ContentFilteredTopic}.

The deletion of a \texttt{ContentFilteredTopic} is not allowed if there are any existing \texttt{DataReader} objects that are using the \texttt{ContentFilteredTopic}. If the \texttt{delete_contentfilteredtopic} operation is called on a \texttt{ContentFilteredTopic} with existing \texttt{DataReader} objects attached to it, it will return PRECONDITION\_NOT\_MET.

The \texttt{delete_contentfilteredtopic} operation must be called on the same \texttt{DomainParticipant} object used to create the \texttt{ContentFilteredTopic}. If \texttt{delete_contentfilteredtopic} is called on a different \texttt{DomainParticipant}, the operation will have no effect and it will return PRECONDITION\_NOT\_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION\_NOT\_MET.

\textbf{2.2.2.1.9 create_multitopic}

This operation creates a \texttt{MultiTopic}. As described in 2.2.2.3, Topic-Definition Module a \texttt{MultiTopic} can be used to subscribe to multiple topics and combine/filter the received data into a resulting type. In particular, \texttt{MultiTopic} provides a content-based subscription mechanism.
The resulting type is specified by the `type_name` argument. Prior to creating a `MultiTopic` the type must have been registered with the Service. This is done using the `register_type` operation on a derived class of the `TypeSupport` interface as described in 2.2.2.3.6.

The list of topics and the logic used to combine filter and re-arrange the information from each `Topic` are specified using the `subscription_expression` and `expression_parameters` arguments.

The syntax of the expression and parameters is described in Annex B.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

### 2.2.2.10 delete_multitopic

This operation deletes a `MultiTopic`.

The deletion of a `MultiTopic` is not allowed if there are any existing `DataReader` objects that are using the `MultiTopic`. If the `delete_multitopic` operation is called on a `MultiTopic` with existing `DataReader` objects attached to it, it will return `PRECONDITION_NOT_MET`.

The `delete_multitopic` operation must be called on the same `DomainParticipant` object used to create the `MultiTopic`. If `delete_multitopic` is called on a different `DomainParticipant`, the operation will have no effect and it will return `PRECONDITION_NOT_MET`.

Possible error codes returned in addition to the standard ones: `PRECONDITION_NOT_MET`.

### 2.2.2.11 find_topic

The operation `find_topic` gives access to an existing (or ready to exist) enabled `Topic`, based on its name. The operation takes as arguments the `name` of the `Topic` and a `timeout`.

If a `Topic` of the same name already exists, it gives access to it, otherwise it waits (blocks the caller) until another mechanism creates it (or the specified timeout occurs). This other mechanism can be another thread, a configuration tool, or some other middleware service. Note that the `Topic` is a local object\(^{10}\) that acts as a ‘proxy’ to designate the global concept of topic. Middleware implementations could choose to propagate topics and make remotely created topics locally available.

A `Topic` obtained by means of `find_topic`, must also be deleted by means of `delete_topic` so that the local resources can be released. If a `Topic` is obtained multiple times by means of `find_topic` or `create_topic`, it must also be deleted that same number of times using `delete_topic`.

Regardless of whether the middleware chooses to propagate topics, the `delete_topic` operation deletes only the local proxy.

If the operation times-out, a ‘nil’ value (as specified by the platform) is returned.

### 2.2.2.12 lookup_topicdescription

The operation `lookup_topicdescription` gives access to an existing locally-created `TopicDescription`, based on its name. The operation takes as argument the `name` of the `TopicDescription`.

If a `TopicDescription` of the same name already exists, it gives access to it, otherwise it returns a ‘nil’ value. The operation never blocks.

\(^{10}\) All the objects that make up this specification are local objects that are actually proxies to the service to be used by the application.
The operation `lookup_topicdescription` may be used to locate any locally-created `Topic`, `ContentFilteredTopic`, and `MultiTopic` object.

Unlike `find_topic`, the operation `lookup_topicdescription` searches only among the locally created topics. Therefore, it should never create a new `TopicDescription`. The `TopicDescription` returned by `lookup_topicdescription` does not require any extra deletion. It is still possible to delete the `TopicDescription` returned by `lookup_topicdescription`, provided it has no readers or writers, but then it is really deleted and subsequent lookups will fail.

If the operation fails to locate a `TopicDescription`, a 'nil' value (as specified by the platform) is returned.

**2.2.2.2.1.13 get_builtin_subscriber**

This operation allows access to the built-in `Subscriber`. Each `DomainParticipant` contains several built-in `Topic` objects as well as corresponding `DataReader` objects to access them. All these `DataReader` objects belong to a single built-in `Subscriber`.

The built-in Topics are used to communicate information about other `DomainParticipant`, `Topic`, `DataReader`, and `DataWriter` objects. These built-in objects are described in 2.2.5, Built-in Topics.

**2.2.2.2.1.14 ignore_participant**

This operation allows an application to instruct the Service to locally ignore a remote domain participant. From that point onwards the Service will locally behave as if the remote participant did not exist. This means it will ignore any `Topic`, publication, or subscription that originates on that domain participant.

This operation can be used, in conjunction with the discovery of remote participants offered by means of the “DCPSParticipant” built-in `Topic`, to provide, for example, access control. Application data can be associated with a `DomainParticipant` by means of the USER_DATA QoS policy. This application data is propagated as a field in the built-in topic and can be used by an application to implement its own access control policy. See 2.2.5, Built-in Topics for more details on the built-in topics.

The domain participant to ignore is identified by the `handle` argument. This handle is the one that appears in the `SampleInfo` retrieved when reading the data-samples available for the built-in `DataReader` to the “DCPSParticipant” topic. The built-in `DataReader` is read with the same `read`/`take` operations used for any `DataReader`. These data-accessing operations are described in 2.2.2.5, Subscription Module.

The `ignore_participant` operation is not required to be reversible. The Service offers no means to reverse it.

Possible error codes returned in addition to the standard ones: OUT_OF_RESOURCES.

**2.2.2.2.1.15 ignore_topic**

This operation allows an application to instruct the Service to locally ignore a `Topic`. This means it will locally ignore any publication or subscription to the `Topic`.

This operation can be used to save local resources when the application knows that it will never publish or subscribe to data under certain topics.

The `Topic` to ignore is identified by the `handle` argument. This handle is the one that appears in the `SampleInfo` retrieved when reading the data-samples from the built-in `DataReader` to the “DCPSTopic” topic.

The `ignore_topic` operation is not required to be reversible. The Service offers no means to reverse it.

Possible error codes returned in addition to the standard ones: OUT_OF_RESOURCES.
2.2.2.2.16 ignore_publication

This operation allows an application to instruct the Service to locally ignore a remote publication; a publication is defined by
the association of a topic name, and user data and partition set on the Publisher (see the “DCPSPublication” built-in Topic in
2.2.5). After this call, any data written related to that publication will be ignored.

The DataWriter to ignore is identified by the handle argument. This handle is the one that appears in the SampleInfo retrieved
when reading the data-samples from the built-in DataReader to the “DCPSPublication” topic.

The ignore_publication operation is not required to be reversible. The Service offers no means to reverse it.

Possible error codes returned in addition to the standard ones: OUT_OF_RESOURCES.

2.2.2.2.17 ignore_subscription

This operation allows an application to instruct the Service to locally ignore a remote subscription; a subscription is defined by
the association of a topic name, and user data and partition set on the Subscriber (see the “DCPSSubscription” built-in Topic
in 2.2.5). After this call, any data received related to that subscription will be ignored.

The DataReader to ignore is identified by the handle argument. This handle is the one that appears in the SampleInfo retrieved
when reading the data-samples from the built-in DataReader to the “DCPSSubscription” topic.

The ignore_subscription operation is not required to be reversible. The Service offers no means to reverse it.

Possible error codes returned in addition to the standard ones: OUT_OF_RESOURCES.

2.2.2.2.18 delete_contained_entities

This operation deletes all the entities that were created by means of the “create” operations on the DomainParticipant. That is,
it deletes all contained Publisher, Subscriber, Topic, ContentFilteredTopic, and MultiTopic.

Prior to deleting each contained entity, this operation will recursively call the corresponding delete_contained_entities
operation on each contained entity (if applicable). This pattern is applied recursively. In this manner the operation
delete_contained_entities on the DomainParticipant will end up deleting all the entities recursively contained in the
DomainParticipant, that is also the DataWriter, DataReader, as well as the QueryCondition and ReadCondition objects
belonging to the contained DataReaders.

The operation will return PRECONDITION_NOT_MET if the any of the contained entities is in a state where it cannot be
deleted.

Once delete_contained_entities returns successfully, the application may delete the DomainParticipant knowing that it has no
contained entities.

2.2.2.2.19 assert_liveliness

This operation manually asserts the liveliness of the DomainParticipant. This is used in combination with the LIVELINESS
QoS policy (cf. 2.2.3, Supported QoS) to indicate to the Service that the entity remains active.

This operation needs to only be used if the DomainParticipant contains DataWriter entities with the LIVELINESS set to
MANUAL_BY_PARTICIPANT and it only affects the liveliness of those DataWriter entities. Otherwise, it has no effect.

NOTE: Writing data via the write operation on a DataWriter asserts liveliness on the DataWriter itself and its
DomainParticipant. Consequently the use of assert_liveliness is only needed if the application is not writing data regularly.

Complete details are provided in 2.2.3.11, LIVELINESS.
2.2.2.2.1.20 set_default_publisher_qos

This operation sets a default value of the Publisher QoS policies which will be used for newly created Publisher entities in the case where the QoS policies are defaulted in the create_publisher operation.

This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return INCONSISTENT_POLICY.

The special value PUBLISHER_QOS_DEFAULT may be passed to this operation to indicate that the default QoS should be reset back to the initial values the factory would use, that is the values that would be used if the set_default_publisher_qos operation had never been called.

2.2.2.2.1.21 get_default_publisher_qos

This operation retrieves the default value of the Publisher QoS, that is, the QoS policies which will be used for newly created Publisher entities in the case where the QoS policies are defaulted in the create_publisher operation.

The values retrieved get_default_publisher_qos will match the set of values specified on the last successful call to set_default_publisher_qos, or else, if the call was never made, the default values listed in the QoS table in 2.2.3, Supported QoS.

2.2.2.2.1.22 set_default_subscriber_qos

This operation sets a default value of the Subscriber QoS policies that will be used for newly created Subscriber entities in the case where the QoS policies are defaulted in the create_subscriber operation.

This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return INCONSISTENT_POLICY.

The special value SUBSCRIBER_QOS_DEFAULT may be passed to this operation to indicate that the default QoS should be reset back to the initial values the factory would use, that is the values that would be used if the set_default_subscriber_qos operation had never been called.

2.2.2.2.1.23 get_default_subscriber_qos

This operation retrieves the default value of the Subscriber QoS, that is, the QoS policies which will be used for newly created Subscriber entities in the case where the QoS policies are defaulted in the create_subscriber operation.

The values retrieved get_default_subscriber_qos will match the set of values specified on the last successful call to set_default_subscriber_qos, or else, if the call was never made, the default values listed in the QoS table in 2.2.3, Supported QoS.

2.2.2.2.1.24 set_default_topic_qos

This operation sets a default value of the Topic QoS policies which will be used for newly created Topic entities in the case where the QoS policies are defaulted in the create_topic operation.

This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return INCONSISTENT_POLICY.

The special value TOPIC_QOS_DEFAULT may be passed to this operation to indicate that the default QoS should be reset back to the initial values the factory would use, that is the values that would be used if the set_default_topic_qos operation had never been called.
2.2.2.2.1.25 get_default_topic_qos

This operation retrieves the default value of the Topic QoS, that is, the QoS policies that will be used for newly created Topic entities in the case where the QoS policies are defaulted in the create_topic operation.

The values retrieved get_default_topic_qos will match the set of values specified on the last successful call to set_default_topic_qos, or else, if the call was never made, the default values listed in the QoS table in 2.2.3, Supported QoS.

2.2.2.2.1.26 get_domain_id

This operation retrieves the domain_id used to create the DomainParticipant. The domain_id identifies the DDS domain to which the DomainParticipant belongs. As described in the introduction to 2.2.2.2.1 each DDS domain represents a separate data “communication plane” isolated from other domains.

2.2.2.2.1.27 get_discovered_participants

This operation retrieves the list of DomainParticipants that have been discovered in the domain and that the application has not indicated should be “ignored” by means of the DomainParticipant ignore_participant operation.

The operation may fail if the infrastructure does not locally maintain the connectivity information. In this case the operation will return UNSUPPORTED.

2.2.2.2.1.28 get_discovered_participant_data

This operation retrieves information on a DomainParticipant that has been discovered on the network. The participant must be in the same domain as the participant on which this operation is invoked and must not have been “ignored” by means of the DomainParticipant ignore_participant operation.

The participant_handle must correspond to such a DomainParticipant. Otherwise, the operation will fail and return PRECONDITION_NOT_MET.

Use the operation get_discovered_participants to find the DomainParticipants that are currently discovered.

The operation may also fail if the infrastructure does not hold the information necessary to fill in the participant_data. In this case the operation will return UNSUPPORTED.

2.2.2.2.1.29 get_discovered_topics

This operation retrieves the list of Topics that have been discovered in the domain and that the application has not indicated should be “ignored” by means of the DomainParticipant ignore_topic operation.

2.2.2.2.1.30 get_discovered_topic_data

This operation retrieves information on a Topic that has been discovered on the network. The topic must have been created by a participant in the same domain as the participant on which this operation is invoked and must not have been “ignored” by means of the DomainParticipant ignore_topic operation.

The topic_handle must correspond to such a topic. Otherwise, the operation will fail and return PRECONDITION_NOT_MET.

Use the operation get_discovered_topics to find the topics that are currently discovered.

The operation may also fail if the infrastructure does not hold the information necessary to fill in the topic_data. In this case the operation will return UNSUPPORTED.
The operation may fail if the infrastructure does not locally maintain the connectivity information. In this case the operation will return UNSUPPORTED.

### 2.2.2.1.31 contains_entity

This operation checks whether or not the given *a_handle* represents an *Entity* that was created from the *DomainParticipant*. The containment applies recursively. That is, it applies both to entities (*TopicDescription, Publisher, or Subscriber*) created directly using the *DomainParticipant* as well as entities created using a contained *Publisher, or Subscriber* as the factory, and so forth.

The instance handle for an *Entity* may be obtained from built-in topic data, from various statuses, or from the Entity operation *get_instance_handle*.

### 2.2.2.1.32 get_current_time

This operation returns the current value of the time that the service uses to time-stamp data-writes and to set the reception-timestamp for the data-updates it receives.

### 2.2.2.2 DomainParticipantFactory Class

The sole purpose of this class is to allow the creation and destruction of *DomainParticipant* objects. *DomainParticipantFactory* itself has no factory. It is a pre-existing singleton object that can be accessed by means of the *get_instance* class operation on the *DomainParticipantFactory*.

<table>
<thead>
<tr>
<th>DomainParticipantFactory</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>

<tr>
<td>QosPolicy []</td>
</tr>
<tr>
<td>get_qos</td>
</tr>
<tr>
<td>out: qos_list</td>
</tr>
<tr>
<td>QosPolicy []</td>
</tr>
</tbody>
</table>
The following sub clauses give details about the operations.

### 2.2.2.2.2.1 create_participant

This operation creates a new `DomainParticipant` object. The `DomainParticipant` signifies that the calling application intends to join the Domain identified by the `domain_id` argument.

If the specified QoS policies are not consistent, the operation will fail and no `DomainParticipant` will be created.

The special value PARTICIPANT_QOS_DEFAULT can be used to indicate that the `DomainParticipant` should be created with the default `DomainParticipant` QoS set in the factory. The use of this value is equivalent to the application obtaining the default `DomainParticipant` QoS by means of the operation `get_default_participant_qos` (2.2.2.2.6) and using the resulting QoS to create the `DomainParticipant`.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

### 2.2.2.2.2 delete_participant

This operation deletes an existing `DomainParticipant`. This operation can only be invoked if all domain entities belonging to the participant have already been deleted. Otherwise the error PRECONDITION_NOT_MET is returned.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

### 2.2.2.2.2.3 get_instance

This operation returns the `DomainParticipantFactory` singleton. The operation is idempotent, that is, it can be called multiple times without side-effects and it will return the same `DomainParticipantFactory` instance.

The `get_instance` operation is a static operation implemented using the syntax of the native language and can therefore not be expressed in the IDL PSM.

The pre-defined value TheParticipantFactory can also be used as an alias for the singleton factory returned by the operation `get_instance`.

### 2.2.2.2.2.4 lookup_participant

This operation retrieves a previously created `DomainParticipant` belonging to specified domain_id. If no such `DomainParticipant` exists, the operation will return a ‘nil’ value.

If multiple `DomainParticipant` entities belonging to that `domain_id` exist, then the operation will return one of them. It is not specified which one.

### 2.2.2.2.2.5 set_default_participant_qos

This operation sets a default value of the `DomainParticipant` QoS policies which will be used for newly created `DomainParticipant` entities in the case where the QoS policies are defaulted in the `create_participant` operation.

This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return INCONSISTENT_POLICY.

<table>
<thead>
<tr>
<th>set_qos</th>
<th>ReturnCode_t</th>
</tr>
</thead>
<tbody>
<tr>
<td>qos_list</td>
<td>QosPolicy []</td>
</tr>
</tbody>
</table>
2.2.2.2.6 get_default_participant_qos

This operation retrieves the default value of the DomainParticipant QoS, that is, the QoS policies which will be used for newly created DomainParticipant entities in the case where the QoS policies are defaulted in the create_participant operation.

The values retrieved get_default_participant_qos will match the set of values specified on the last successful call to set_default_participant_qos, or else, if the call was never made, the default values listed in the QoS table in 2.2.3, Supported QoS.

2.2.2.2.7 set_qos

This operation sets the value of the DomainParticipantFactory QoS policies. These policies control the behavior of the object a factory for entities.

Note that despite having QoS, the DomainParticipantFactory is not an Entity.

This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return INCONSISTENT_POLICY.

2.2.2.2.8 get_qos

This operation returns the value of the DomainParticipantFactory QoS policies.

2.2.2.3 DomainParticipantListener Interface

This is the interface that can be implemented by an application-provided class and then registered with the DomainParticipant such that the application can be notified by the DCPS Service of relevant status changes.

The DomainParticipantListener interface extends all other Listener interfaces and has no additional operation beyond the ones defined by the more general listeners.

<table>
<thead>
<tr>
<th>DomainParticipantListener</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>on_inconsistent_topic</td>
</tr>
<tr>
<td>the_topic</td>
</tr>
<tr>
<td>status</td>
</tr>
<tr>
<td>on_liveliness_lost</td>
</tr>
<tr>
<td>the_writer</td>
</tr>
<tr>
<td>status</td>
</tr>
<tr>
<td>on_offered_deadline_missed</td>
</tr>
<tr>
<td>the_writer</td>
</tr>
<tr>
<td>status</td>
</tr>
<tr>
<td>on_offered_incompatible_qos</td>
</tr>
<tr>
<td>the_writer</td>
</tr>
<tr>
<td>status</td>
</tr>
<tr>
<td>on_data_on_readers</td>
</tr>
<tr>
<td>the_subscriber</td>
</tr>
</tbody>
</table>
The purpose of the `DomainParticipantListener` is to be the listener of last resort that is notified of all status changes not captured by more specific listeners attached to the `DomainEntity` objects. When a relevant status change occurs, the DCPS Service will first attempt to notify the listener attached to the concerned `DomainEntity` if one is installed. Otherwise, the DCPS Service will notify the `Listener` attached to the `DomainParticipant`. The relationship between listeners is described in 2.2.4, Listeners, Conditions, and Wait-sets.
2.2.2.3 Topic-Definition Module

The Topic-Definition Module is comprised of the following classes:

- TopicDescription
- Topic
- ContentFilteredTopic
- MultiTopic
- TopicListener
- TypeSupport

2.2.2.3.1 TopicDescription Class

This class is an abstract class. It is the base class for Topic, ContentFilteredTopic, and MultiTopic.
**TopicDescription**

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>string</td>
</tr>
<tr>
<td>type_name</td>
<td>string</td>
</tr>
</tbody>
</table>

**Operations**

- get_participant: DomainParticipant
- get_type_name: string
- get_name: string

*TopicDescription* represents the fact that both publications and subscriptions are tied to a single data-type. Its attribute *type_name* defines a unique resulting type for the publication or the subscription and therefore creates an implicit association with a *TypeSupport*. *TopicDescription* has also a *name* that allows it to be retrieved locally.

### 2.2.2.3.1.1 get_participant

This operation returns the *DomainParticipant* to which the *TopicDescription* belongs.

### 2.2.2.3.1.2 type_name

The *type_name* used to create the *TopicDescription*.

### 2.2.2.3.1.3 name

The *name* used to create the *TopicDescription*.

### 2.2.2.3.2 Topic Class

*Topic* is the most basic description of the data to be published and subscribed.

**Topic**

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>(inherited) get_qos</td>
<td>ReturnCode_t</td>
</tr>
<tr>
<td>out: qos_list</td>
<td>QosPolicy []</td>
</tr>
<tr>
<td>(inherited) set_qos</td>
<td>ReturnCode_t</td>
</tr>
<tr>
<td>qos_list</td>
<td>QosPolicy []</td>
</tr>
<tr>
<td>(inherited) get_listener</td>
<td>Listener</td>
</tr>
<tr>
<td>(inherited) set_listener</td>
<td>ReturnCode_t</td>
</tr>
<tr>
<td>a_listener</td>
<td>Listener</td>
</tr>
<tr>
<td>mask</td>
<td>StatusKind []</td>
</tr>
<tr>
<td>get_inconsistent_topic_status</td>
<td>ReturnCode_t</td>
</tr>
<tr>
<td>out: status</td>
<td>InconsistentTopicStatus</td>
</tr>
</tbody>
</table>
A Topic is identified by its **name**, which must be unique in the whole Domain. In addition (by virtue of extending **TopicDescription**) it fully specifies the type of the data that can be communicated when publishing or subscribing to the **Topic**.

**Topic** is the only **TopicDescription** that can be used for publications and therefore associated to a **DataWriter**.

All operations except for the base-class operations **set_qos**, **get_qos**, **set_listener**, **get_listener**, **enable** and **get_status_condition** may return the value **NOT_ENABLED**.

The following sub clauses describe its operations.

### 2.2.2.3.2.1 get_inconsistent_topic_status

This method allows the application to retrieve the INCONSISTENT_TOPIC status of the **Topic**.

Each **DomainEntity** has a set of relevant communication statuses. A change of status causes the corresponding **Listener** to be invoked and can also be monitored by means of the associated **StatusCondition**.

The complete list of communication status, their values, and the **DomainEntities** they apply to is provided in 2.2.4.1, Communication Status.

### 2.2.2.3.3 ContentFilteredTopic Class

**ContentFilteredTopic** is a specialization of **TopicDescription** that allows for content-based subscriptions.

<table>
<thead>
<tr>
<th><strong>ContentFilteredTopic</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>attributes</strong></td>
</tr>
<tr>
<td>readonly: filter_expression string</td>
</tr>
<tr>
<td><strong>operations</strong></td>
</tr>
<tr>
<td>get_related_topic Topic</td>
</tr>
<tr>
<td>get_expression_parameters out: expression_parameters string[]</td>
</tr>
<tr>
<td>set_expression_parameters expression_parameters string[]</td>
</tr>
</tbody>
</table>

**ContentFilteredTopic** describes a more sophisticated subscription that indicates the subscriber does not want to necessarily see all values of each instance published under the **Topic**. Rather, it wants to see only the values whose contents satisfy certain criteria. This class therefore can be used to request content-based subscriptions.

The selection of the content is done using the **filter_expression** with parameters **expression_parameters**.

- The **filter_expression** attribute is a string that specifies the criteria to select the data samples of interest. It is similar to the WHERE part of an SQL clause.

- The **expression_parameters** attribute is a sequence of strings that give values to the ‘parameters’ (i.e., "%n" tokens) in the **filter_expression**. The number of supplied parameters must fit with the requested values in the **filter_expression** (i.e., the number of %n tokens).
Annex B describes the syntax of filter_expression and expression_parameters.

2.2.2.3.3.1 get_related_topic

This operation returns the Topic associated with the ContentFilteredTopic. That is, the Topic specified when the ContentFilteredTopic was created.

2.2.2.3.3.2 filter_expression

The filter_expression associated with the ContentFilteredTopic. That is, the expression specified when the ContentFilteredTopic was created.

2.2.2.3.3.3 get_expression_parameters

This operation returns the expression_parameters associated with the ContentFilteredTopic. That is, the parameters specified on the last successful call to set_expression_parameters, or if set_expression_parameters was never called, the parameters specified when the ContentFilteredTopic was created.

2.2.2.3.3.4 set_expression_parameters

This operation changes the expression_parameters associated with the ContentFilteredTopic.

2.2.2.3.4 MultiTopic Class [optional]

MultiTopic is a specialization of TopicDescription that allows subscriptions to combine/filter/rearrange data coming from several topics.

<table>
<thead>
<tr>
<th>MultiTopic</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
</tr>
<tr>
<td>readonly: subscription_expression</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>get_expression_parameters</td>
</tr>
<tr>
<td>out: expression_parameters</td>
</tr>
<tr>
<td>set_expression_parameters</td>
</tr>
<tr>
<td>expression_parameters</td>
</tr>
</tbody>
</table>

MultiTopic allows a more sophisticated subscription that can select and combine data received from multiple topics into a single resulting type (specified by the inherited type_name). The data will then be filtered (selection) and possibly re-arranged (aggregation/projection) according to a subscription_expression with parameters expression_parameters.
• The `subscription_expression` is a string that identifies the selection and re-arrangement of data from the associated topics. It is similar to an SQL clause where the SELECT part provides the fields to be kept, the FROM part provides the names of the topics that are searched for those fields\(^\text{11}\), and the WHERE clause gives the content filter. The Topics combined may have different types but they are restricted in that the type of the fields used for the NATURAL JOIN operation must be the same.

• The `expression_parameters` attribute is a sequence of strings that give values to the ‘parameters’ (i.e., "%n" tokens) in the `subscription_expression`. The number of supplied parameters must fit with the requested values in the `subscription_expression` (i.e., the number of %n tokens).

• `DataReader` entities associated with a `MultiTopic` are alerted of data modifications by the usual `Listener` or `Condition` mechanisms (see 2.2.4, Listeners, Conditions, and Wait-sets) whenever modifications occur to the data associated with any of the topics relevant to the `MultiTopic`.

• `DataReader` entities associated with a `MultiTopic` access instances that are “constructed” at the `DataReader` side from the instances written by multiple `DataWriter` entities. The `MultiTopic` access instance will begin to exist as soon as all the constituting `Topic` instances are in existence. The `view_state` and `instance_state` is computed from the corresponding states of the constituting instances:
  
  • The `view_state` (see 2.2.2.5.1) of the `MultiTopic` instance is NEW if at least one of the constituting instances has `view_state` = NEW, otherwise it will be NOT_NEW.
  
  • The `instance_state` (see 2.2.2.5.1) of the `MultiTopic` instance is “ALIVE” if the `instance_state` of all the constituting `Topic` instances is ALIVE. It is “NOT_ALIVE_DISPOSED” if at least one of the constituting `Topic` instances is NOT_ALIVE_DISPOSED. Otherwise it is NOT_ALIVE_NO_WRITERS.

Annex B describes the syntax of `subscription_expression` and `expression_parameters`.

2.2.2.3.4.1 `subscription_expression`

The `subscription_expression` associated with the `MultiTopic`. That is, the expression specified when the `MultiTopic` was created.

2.2.2.3.4.2 `get_expression_parameters`

This operation returns the `expression_parameters` associated with the `MultiTopic`. That is, the parameters specified on the last successful call to `set_expression_parameters`, or if `set_expression_parameters` was never called, the parameters specified when the `MultiTopic` was created.

2.2.2.3.4.3 `set_expression_parameters`

This operation changes the `expression_parameters` associated with the `MultiTopic`.

---

\(^{11}\) It should be noted that in that case, the source for data may not be restricted to a single topic.
2.2.2.3.5 TopicListener Interface

Since *Topic* is a kind of *Entity*, it has the ability to have an associated listener. In this case, the associated listener should be of concrete type *TopicListener*.

<table>
<thead>
<tr>
<th>TopicListener</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>on_inconsistent_topic</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

2.2.2.3.6 TypeSupport Interface

The *TypeSupport* interface is an abstract interface that has to be specialized for each concrete type that will be used by the application.

It is required that each implementation of the Service provides an automatic means to generate this type-specific class from a description of the type (using IDL, for example, in the OMG IDL mapping). A *TypeSupport* must be registered using the `register_type` operation on this type-specific class before it can be used to create *Topic* objects.

<table>
<thead>
<tr>
<th>TypeSupport</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>register_type</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

2.2.2.3.6.1 register_type

This operation allows an application to communicate to the Service the existence of a data type. The generated implementation of that operation embeds all the knowledge that has to be communicated to the middleware in order to make it able to manage the contents of data of that data type. This includes in particular the *key* definition that will allow the Service to distinguish different instances of the same type.

It is a pre-condition error to use the same *type_name* to register two different *TypeSupport* with the same *DomainParticipant*. If an application attempts this, the operation will fail and return PRECONDITION_NOT_MET. However, it is allowed to register the same *TypeSupport* multiple times with a *DomainParticipant* using the same or different values for the *type_name*. If `register_type` is called multiple times on the same *TypeSupport* with the same *DomainParticipant* and *type_name* the second (and subsequent) registrations are ignored but the operation returns OK.

The application may pass nil as the value for the *type_name*. In this case the default type-name as defined by the *TypeSupport* (i.e., the value returned by the `get_type_name` operation) will be used.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET and OUT_OF_RESOURCES.
2.2.2.3.6.2 \textit{get\_type\_name}

This operation returns the default name for the data-type represented by the \textit{TypeSupport}.

2.2.2.3.7 Derived Classes for Each Application Class

For each data class defined by the application, there is a number of specialized classes that are required to facilitate the type-safe interaction of the application with the Service.

It is required that each implementation of the Service provides an automatic means to generate all these type-specific classes. \textit{TypeSupport} is one of the interfaces that these automatically-generated classes must implement. The complete set of automatic classes created for a hypothetical application data-type named “Foo” are shown in Figure 2.8.

![Diagram showing classes auto-created for an application data type named Foo]

\textbf{Figure 2.8 - Classes auto-created for an application data type named Foo}
2.2.2.4 Publication Module

![Class model of the DCPS Publication Module](image)

**Figure 2.9 - Class model of the DCPS Publication Module**

The DCPS Publication Module is comprised of the following classifiers:

- Publisher
- DataWriter
- PublisherListener
- DataWriterListener
### 2.2.2.4.1 Publisher Class

A Publisher is the object responsible for the actual dissemination of publications.

<table>
<thead>
<tr>
<th>Publisher</th>
<th>no attributes</th>
<th>operations</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>(inherited) get_qos</td>

<td></td>
<td>out: qos_list</td>
</tr>
<tr>
<td></td>
<td></td>
<td>copy_from_topic_qos</td>
</tr>
<tr>
<td></td>
<td></td>
<td>inout: a_datawriter_qos</td>
</tr>
<tr>
<td></td>
<td></td>
<td>a_topic_qos</td>
</tr>
</tbody>
</table>
The Publisher acts on the behalf of one or several DataWriter objects that belong to it. When it is informed of a change to the data associated with one of its DataWriter objects, it decides when it is appropriate to actually send the data-update message. In making this decision, it considers any extra information that goes with the data (timestamp, writer, etc.) as well as the QoS of the Publisher and the DataWriter.

All operations except for the base-class operations set_qos, get_qos, set_listener, get_listener, enable, get_statuscondition, create_datawriter, and delete_datawriter may return the value NOT_ENABLED.

2.2.2.4.1.1 set_listener (from Entity)

By virtue of extending Entity, a Publisher can be attached to a Listener at creation time or later by using the set_listener operation. The Listener attached must extend PublisherListener. Listeners are described in 2.2.4, Listeners, Conditions, and Wait-sets.

2.2.2.4.1.2 get_listener (from Entity)

Retrieves the attached PublisherListener.

2.2.2.4.1.3 set_qos (from Entity)

By virtue of extending Entity, a Publisher can be given QoS at creation time or later by using the set_qos operation. See 2.2.3, Supported QoS for the QoS policies that may be set on a Publisher.

Possible error codes returned in addition to the standard ones: IMMUTABLE_POLICY, INCONSISTENT_POLICY.

2.2.2.4.1.4 get_qos (from Entity)

Allows access to the values of the QoS.

2.2.2.4.1.5 create_datawriter

This operation creates a DataWriter. The returned DataWriter will be attached and belongs to the Publisher.

The DataWriter returned by the create_datawriter operation will in fact be a derived class, specific to the data-type associated with the Topic. As described in 2.2.2.3.7, for each application-defined type “Foo” there is an implied, auto-generated class FooDataWriter that extends DataWriter and contains the operations to write data of type “Foo.”

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

Note that a common application pattern to construct the QoS for the DataWriter is to:

- Retrieve the QoS policies on the associated Topic by means of the get_qos operation on the Topic.
- Retrieve the default DataWriter qos by means of the get_default_datawriter_qos operation on the Publisher.
- Combine those two QoS policies and selectively modify policies as desired.
- Use the resulting QoS policies to construct the DataWriter.

The special value DATAWRITER_QOS_DEFAULT can be used to indicate that the DataWriter should be created with the default DataWriter QoS set in the factory. The use of this value is equivalent to the application obtaining the default DataWriter QoS by means of the operation get_default_datawriter_qos (2.2.2.4.1.15) and using the resulting QoS to create the DataWriter.
The special value DATAWRITER_QOS_USE_TOPIC_QOS can be used to indicate that the DataWriter should be created with a combination of the default DataWriter QoS and the Topic QoS. The use of this value is equivalent to the application obtaining the default DataWriter QoS and the Topic QoS (by means of the operation Topic::get_qos) and then combining these two QoS using the operation copy_from_topic_qos whereby any policy that is set on the Topic QoS “overrides” the corresponding policy on the default QoS. The resulting QoS is then applied to the creation of the DataWriter.

The Topic passed to this operation must have been created from the same DomainParticipant that was used to create this Publisher. If the Topic was created from a different DomainParticipant, the operation will fail and return a nil result.

2.2.4.1.6 delete_datawriter

This operation deletes a DataWriter that belongs to the Publisher.

The delete_datawriter operation must be called on the same Publisher object used to create the DataWriter. If delete_datawriter is called on a different Publisher, the operation will have no effect and it will return PRECONDITION_NOT_MET.

The deletion of the DataWriter will automatically unregister all instances. Depending on the settings of the WRITER_DATA_LIFECYCLE QosPolicy, the deletion of the DataWriter may also dispose all instances. Refer to 2.2.3.21 for details.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

2.2.4.1.7 lookup_datawriter

This operation retrieves a previously created DataWriter belonging to the Publisher that is attached to a Topic with a matching topic_name. If no such DataWriter exists, the operation will return ‘nil.’

If multiple DataWriter attached to the Publisher satisfy this condition, then the operation will return one of them. It is not specified which one.

2.2.4.1.8 suspend_publications

This operation indicates to the Service that the application is about to make multiple modifications using DataWriter objects belonging to the Publisher.

It is a hint to the Service so it can optimize its performance by e.g., holding the dissemination of the modifications and then batching them.

It is not required that the Service use this hint in any way.

The use of this operation must be matched by a corresponding call to resume_publications indicating that the set of modifications has completed. If the Publisher is deleted before resume_publications is called, any suspended updates yet to be published will be discarded.

2.2.4.1.9 resume_publications

This operation indicates to the Service that the application has completed the multiple changes initiated by the previous suspend_publications. This is a hint to the Service that can be used by a Service implementation to e.g., batch all the modifications made since the suspend_publications.

The call to resume_publications must match a previous call to suspend_publications. Otherwise the operation will return the error PRECONDITION_NOT_MET.
Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

2.2.2.4.1.10 begin_coherent_changes

This operation requests that the application will begin a ‘coherent set’ of modifications using DataWriter objects attached to the Publisher. The ‘coherent set’ will be completed by a matching call to end_coherent_changes.

A ‘coherent set’ is a set of modifications that must be propagated in such a way that they are interpreted at the receivers’ side as a consistent set of modifications; that is, the receiver will only be able to access the data after all the modifications in the set are available at the receiver end.

A connectivity change may occur in the middle of a set of coherent changes; for example, the set of partitions used by the Publisher or one of its Subscribers may change, a late-joining DataReader may appear on the network, or a communication failure may occur. In the event that such a change prevents an entity from receiving the entire set of coherent changes, that entity must behave as if it had received none of the set.

These calls can be nested. In that case, the coherent set terminates only with the last call to end_coherent_changes.

The support for ‘coherent changes’ enables a publishing application to change the value of several data-instances that could belong to the same or different topics and have those changes be seen ‘atomically’ by the readers. This is useful in cases where the values are inter-related (for example, if there are two data-instances representing the ‘altitude’ and ‘velocity vector’ of the same aircraft and both are changed, it may be useful to communicate those values in a way the reader can see both together; otherwise, it may e.g., erroneously interpret that the aircraft is on a collision course).

2.2.2.4.1.11 end_coherent_changes

This operation terminates the ‘coherent set’ initiated by the matching call to begin_coherent_changes. If there is no matching call to begin_coherent_changes, the operation will return the error PRECONDITION_NOT_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET

2.2.2.4.1.12 wait_for_acknowledgments

This operation blocks the calling thread until either all data written by the reliable DataWriter entities is acknowledged by all matched reliable DataReader entities, or else the duration specified by the max_wait parameter elapses, whichever happens first. A return value of OK indicates that all the samples written have been acknowledged by all reliable matched data readers; a return value of TIMEOUT indicates that max_wait elapsed before all the data was acknowledged.

2.2.2.4.1.13 get_participant

This operation returns the DomainParticipant to which the Publisher belongs.

2.2.2.4.1.14 delete_contained_entities

This operation deletes all the entities that were created by means of the “create” operations on the Publisher. That is, it deletes all contained DataWriter objects.

The operation will return PRECONDITION_NOT_MET if the any of the contained entities is in a state where it cannot be deleted.

12. This does not imply that the middleware has to encapsulate all the modifications in a single message; it only implies that the receiving applications will behave as if this was the case.
Once `delete_contained_entities` returns successfully, the application may delete the `Publisher` knowing that it has no contained `DataWriter` objects.

### 2.2.2.4.1.15 set_default_datawriter_qos

This operation sets a default value of the `DataWriter` QoS policies which will be used for newly created `DataWriter` entities in the case where the QoS policies are defaulted in the `create_datawriter` operation.

This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return `INCONSISTENT_POLICY`.

The special value `DATAWRITER_QOS_DEFAULT` may be passed to this operation to indicate that the default QoS should be reset back to the initial values the factory would use, that is the values that would be used if the `set_default_datawriter_qos` operation had never been called.

### 2.2.2.4.1.16 get_default_datawriter_qos

This operation retrieves the default value of the `DataWriter` QoS, that is, the QoS policies which will be used for newly created `DataWriter` entities in the case where the QoS policies are defaulted in the `create_datawriter` operation.

The values retrieved by `get_default_datawriter_qos` will match the set of values specified on the last successful call to `set_default_datawriter_qos`, or else, if the call was never made, the default values listed in the QoS table in 2.2.3, Supported QoS.

### 2.2.2.4.1.17 copy_from_topic_qos

This operation copies the policies in the `a_topic_qos` to the corresponding policies in the `a_datawriter_qos` (replacing values in the `a_datawriter_qos`, if present).

This is a “convenience” operation most useful in combination with the operations `get_default_datawriter_qos` and `Topic::get_qos`. The operation `copy_from_topic_qos` can be used to merge the `DataWriter` default QoS policies with the corresponding ones on the `Topic`. The resulting QoS can then be used to create a new `DataWriter`, or set its QoS.

This operation does not check the resulting `a_datawriter_qos` for consistency. This is because the ‘merged’ `a_datawriter_qos` may not be the final one, as the application can still modify some policies prior to applying the policies to the `DataWriter`.

### 2.2.2.4.2 DataWriter Class

`DataWriter` allows the application to set the value of the data to be published under a given `Topic`.

A **DataWriter** is attached to exactly one **Publisher** that acts as a factory for it.

A **DataWriter** is bound to exactly one **Topic** and therefore to exactly one data type. The **Topic** must exist prior to the **DataWriter**’s creation.

**DataWriter** is an abstract class. It must be specialized for each particular application data-type as shown in Figure 2.8. The additional methods that must be defined in the auto-generated class for a hypothetical application type “Foo” are shown in the table below:

All operations except for the base-class operations `set_qos`, `get_qos`, `set_listener`, `get_listener`, `enable`, and `get_statuscondition` may return the value NOT_ENABLED.

The following sub clauses provide details on the methods.

### 2.2.2.4.2.1 set_listener (from Entity)

By virtue of extending `Entity`, a `DataWriter` can be attached to a `Listener` at creation time or later by using the `set_listener` operation. The attached `Listener` must extend `DataWriterListener`. Listeners are described in 2.2.4, Listeners, Conditions, and Wait-sets.

### 2.2.2.4.2.2 get_listener (from Entity)

Allows access to the attached `DataWriterListener`.

### 2.2.2.4.2.3 set_qos (from Entity)

By virtue of extending `Entity`, a `DataWriter` can be given QoS at creation time or later by using the `set_qos` operation. See 2.2.3, Supported QoS for the QoS policies that may be set on a `DataWriter`.

Possible error codes returned in addition to the standard ones: IMMUTABLE_POLICY, INCONSISTENT_POLICY.

### 2.2.2.4.2.4 get_qos (from Entity)

Allows access to the values of the QoS.

### 2.2.2.4.2.5 register_instance

This operation informs the Service that the application will be modifying a particular instance. It gives an opportunity to the Service to pre-configure itself to improve performance.

It takes as a parameter an instance (to get the key value) and returns a handle that can be used in successive write or dispose operations.
This operation should be invoked prior to calling any operation that modifies the instance, such as `write`, `write_w_timestamp`, `dispose` and `dispose_w_timestamp`.

The special value HANDLE_NIL may be returned by the Service if it does not want to allocate any handle for that instance.

This operation may block and return TIMEOUT under the same circumstances described for the `write` operation (2.2.2.4.2.11).

This operation may return OUT_OF_RESOURCES under the same circumstances described for the `write` operation (2.2.2.4.2.11).

The operation `register_instance` is idempotent. If it is called for an already registered instance, it just returns the already allocated handle. This may be used to lookup and retrieve the handle allocated to a given instance. The explicit use of this operation is optional as the application may call directly the `write` operation and specify a HANDLE_NIL to indicate that the ‘key’ should be examined to identify the instance.

### 2.2.2.4.2.6 register_instance_w_timestamp

This operation performs the same function as `register_instance` and can be used instead of `register_instance` in the cases where the application desires to specify the value for the `source_timestamp`. The `source_timestamp` potentially affects the relative order in which readers observe events from multiple writers. For details see 2.2.3.17 for the QoS policy DESTINATION_ORDER).

This operation may block and return TIMEOUT under the same circumstances described for the `write` operation (2.2.2.4.2.11).

This operation may return OUT_OF_RESOURCES under the same circumstances described for the `write` operation (2.2.2.4.2.11).

### 2.2.2.4.2.7 unregister_instance

This operation reverses the action of `register_instance`. It should only be called on an instance that is currently registered.

The operation `unregister_instance` should be called just once per instance, regardless of how many times `register_instance` was called for that instance.

This operation informs the Service that the DataWriter is not intending to modify any more of that data instance. This operation also indicates that the Service can locally remove all information regarding that instance. The application should not attempt to use the handle previously allocated to that instance after calling `unregister_instance`.

The special value HANDLE_NIL can be used for the parameter `handle`. This indicates that the identity of the instance should be automatically deduced from the `instance` (by means of the `key`).

If `handle` is any value other than HANDLE_NIL, then it must correspond to the value returned by `register_instance` when the instance (identified by its `key`) was registered. Otherwise the behavior is as follows:

- If the `handle` corresponds to an existing instance but does not correspond to the same instance referred by the 'instance' parameter, the behavior is in general unspecified, but if detectable by the Service implementation, the operation shall fail and return the error-code PRECONDITION_NOT_MET.'

- If the `handle` does not correspond to an existing instance the behavior is in general unspecified, but if detectable by the Service implementation, the operation shall fail and return the error-code 'BAD_PARAMETER.'

If after that, the application wants to modify (write or dispose) the instance, it has to register it again, or else use the special `handle` value HANDLE_NIL.
This operation does not indicate that the instance is deleted (that is the purpose of dispose). The operation unregister_instance just indicates that the DataWriter no longer has ‘anything to say’ about the instance. DataReader entities that are reading the instance will eventually receive a sample with a NOT_ALIVE_NO_WRITERS instance state if no other DataWriter entities are writing the instance.

This operation can affect the ownership of the data instance (as described in 2.2.3.9, OWNERSHIP and 2.2.3.23.1, Ownership resolution on redundant systems). If the DataWriter was the exclusive owner of the instance, then calling unregister_instance will relinquish that ownership.

This operation may block and return TIMEOUT under the same circumstances described for the write operation (2.2.2.4.2.11, write).

Possible error codes returned in addition to the standard ones: TIMEOUT, PRECONDITION_NOT_MET.

2.2.2.4.2.8 unregister_instance_w_timestamp

This operation performs the same function as unregister_instance and can be used instead of unregister_instance in the cases where the application desires to specify the value for the source_timestamp. The source_timestamp potentially affects the relative order in which readers observe events from multiple writers. For details see 2.2.3.17 for the QoS policy DESTINATION_ORDER).

The constraints on the values of the handle parameter and the corresponding error behavior are the same specified for the unregister_instance operation (2.2.2.4.2.7).

This operation may block and return TIMEOUT under the same circumstances described for the write operation (2.2.2.4.2.11).

2.2.2.4.2.9 get_key_value

This operation can be used to retrieve the instance key that corresponds to an instance_handle. The operation will only fill the fields that form the key inside the key_holder instance.

This operation may return BAD_PARAMETER if the InstanceHandle_t a_handle does not correspond to an existing data-object known to the DataWriter. If the implementation is not able to check invalid handles, then the result in this situation is unspecified.

2.2.2.4.2.10 lookup_instance

This operation takes as a parameter an instance and returns a handle that can be used in subsequent operations that accept an instance handle as an argument. The instance parameter is only used for the purpose of examining the fields that define the key.

This operation does not register the instance in question. If the instance has not been previously registered, or if for any other reason the Service is unable to provide an instance handle, the Service will return the special value HANDLE_NIL.

2.2.2.4.2.11 write

This operation modifies the value of a data instance. When this operation is used, the Service will automatically supply the value of the source_timestamp that is made available to DataReader objects by means of the source_timestamp attribute inside the SampleInfo. See 2.2.2.5, Subscription Module for more details on data timestamps at reader side and 2.2.3.17 for the QoS policy DESTINATION_ORDER.

This operation must be provided on the specialized class that is generated for the particular application data-type that is being written. That way the data argument holding the data has the proper application-defined type (e.g., ‘Foo’).
As a side effect, this operation asserts liveliness on the DataWriter itself, the Publisher and the DomainParticipant.

The special value HANDLE_NIL can be used for the parameter handle. This indicates that the identity of the instance should be automatically deduced from the instance_data (by means of the key).

If handle is any value other than HANDLE_NIL, then it must correspond to the value returned by register_instance when the instance (identified by its key) was registered. Otherwise the behavior is as follows:

- If the handle corresponds to an existing instance but does not correspond to the same instance referred by the ‘data’ parameter, the behavior is in general unspecified, but if detectable by the Service implementation, the operation shall fail and return the error-code PRECONDITION_NOT_MET.
- If the handle does not correspond to an existing instance the behavior is in general unspecified, but if detectable by the Service implementation, the operation shall fail and return the error-code BAD_PARAMETER.

If the RELIABILITY kind is set to RELIABLE, the write operation may block if the modification would cause data to be lost or else cause one of the limits specified in the RESOURCE_LIMITS to be exceeded. Under these circumstances, the RELIABILITY max_blocking_time configures the maximum time the write operation may block waiting for space to become available. If max_blocking_time elapses before the DataWriter is able to store the modification without exceeding the limits, the write operation will fail and return TIMEOUT.

Specifically, the DataWriter write operation may block in the following situations (note that the list may not be exhaustive), even if its HISTORY kind is KEEP_LAST.

- If (RESOURCE_LIMITS max_samples < RESOURCE_LIMITS max_instances * HISTORY depth), then in the situation where the max_samples resource limit is exhausted the Service is allowed to discard samples of some other instance as long as at least one sample remains for such an instance. If it is still not possible to make space available to store the modification, the writer is allowed to block.
- If (RESOURCE_LIMITS max_samples < RESOURCE_LIMITS max_instances), then the DataWriter may block regardless of the HISTORY depth.

Instead of blocking, the write operation is allowed to return immediately with the error code OUT_OF_RESOURCES provided the following two conditions are met:

1. The reason for blocking would be that the RESOURCE_LIMITS are exceeded.
2. The service determines that waiting the max_waiting_time has no chance of freeing the necessary resources. For example, if the only way to gain the necessary resources would be for the user to unregister an instance.

In case the provided handle is valid, i.e., corresponds to an existing instance, but does not correspond to same instance referred by the ‘data’ parameter, the behavior is in general unspecified, but if detectable by the Service implementation, the return error-code will be PRECONDITION_NOT_MET. In case the handle is invalid, the behavior is in general unspecified, but if detectable the returned error-code will be BAD_PARAMETER.

2.2.2.4.2.12 write_w_timestamp

This operation performs the same function as write except that it also provides the value for the source_timestamp that is made available toDataReader objects by means of the source_timestamp attribute inside the SampleInfo. See 2.2.2.5, Subscription Module for more details on data timestamps at reader side and 2.2.3.17 for the QoS policy DESTINATION_ORDER.

The constraints on the values of the handle parameter and the corresponding error behavior are the same specified for the write operation (2.2.2.4.2.11).

This operation may block and return TIMEOUT under the same circumstances described for the write operation (2.2.2.4.2.11).
This operation may return OUT_OF_RESOURCES under the same circumstances described for the write operation (2.2.2.4.2.11).

This operation may return PRECONDITION_NOT_MET under the same circumstances described for the write operation (2.2.2.4.2.11).

This operation may return BAD_PARAMETER under the same circumstances described for the write operation (2.2.2.4.2.11).

Similar to write, this operation must also be provided on the specialized class that is generated for the particular application data-type that is being written.

2.2.2.4.2.13 dispose

This operation requests the middleware to delete the data (the actual deletion is postponed until there is no more use for that data in the whole system). In general, applications are made aware of the deletion by means of operations on the DataReader objects that already knew that instance13 (see 2.2.2.5, Subscription Module for more details).

This operation does not modify the value of the instance. The instance parameter is passed just for the purposes of identifying the instance.

When this operation is used, the Service will automatically supply the value of the source_timestamp that is made available to DataReader objects by means of the source_timestamp attribute inside the SampleInfo.

The constraints on the values of the handle parameter and the corresponding error behavior are the same specified for the unregister_instance operation (2.2.2.4.2.7).

This operation may block and return TIMEOUT under the same circumstances described for the write operation (2.2.2.4.2.11).

This operation may return OUT_OF_RESOURCES under the same circumstances described for the write operation (2.2.2.4.2.11).

2.2.2.4.2.14 dispose_w_timestamp

This operation performs the same functions as dispose except that the application provides the value for the source_timestamp that is made available to DataReader objects by means of the source_timestamp attribute inside the SampleInfo (see 2.2.2.5, Subscription Module).

The constraints on the values of the handle parameter and the corresponding error behavior are the same specified for the dispose operation (2.2.2.4.2.13).

This operation may return PRECONDITION_NOT_MET under the same circumstances described for the dispose operation (2.2.2.4.2.13).

This operation may return BAD_PARAMETER under the same circumstances described for the dispose operation (2.2.2.4.2.13).

This operation may block and return TIMEOUT under the same circumstances described for the write operation (2.2.2.4.2.11).

This operation may return OUT_OF_RESOURCES under the same circumstances described for the write operation (2.2.2.4.2.11).

13. DataReader objects that didn't know the instance will never see it.
Possible error codes returned in addition to the standard ones: TIMEOUT, PRECONDITION_NOT_MET.

2.2.2.4.2.15 wait_for_acknowledgments

This operation is intended to be used only if the DataWriter has RELIABILITY QoS kind set to RELIABLE. Otherwise the operation will return immediately with RETCODE_OK.

The operation wait_for_acknowledgments blocks the calling thread until either all data written by the DataWriter is acknowledged by all matched DataReader entities that have RELIABILITY QoS kind RELIABLE, or else the duration specified by the max_wait parameter elapses, whichever happens first. A return value of OK indicates that all the samples written have been acknowledged by all reliable matched data readers; a return value of TIMEOUT indicates that max_wait elapsed before all the data was acknowledged.

2.2.2.4.2.16 get_liveliness_lost_status

This operation allows access to the LIVELINESS_LOST communication status. Communication statuses are described in 2.2.4.1, Communication Status.

2.2.2.4.2.17 get_offered_deadline_missed_status

This operation allows access to the OFFERED_DEADLINE_MISSED communication status. Communication statuses are described in 2.2.4.1, Communication Status.

2.2.2.4.2.18 get_offered_incompatible_qos_status

This operation allows access to the OFFERED_INCOMPATIBLE_QOS communication status. Communication statuses are described in 2.2.4.1, Communication Status.

2.2.2.4.2.19 get_publication_matched_status

This operation allows access to the PUBLICATION_MATCHED communication status. Communication statuses are described in 2.2.4.1, Communication Status.

2.2.2.4.2.20 get_topic

This operation returns the Topic associated with the DataWriter. This is the same Topic that was used to create the DataWriter.

2.2.2.4.2.21 get_publisher

This operation returns the Publisher to which the DataWriter belongs.

2.2.2.4.2.22 assert_liveliness

This operation manually asserts the liveliness of the DataWriter. This is used in combination with the LIVELINESS QoS policy (see 2.2.3, Supported QoS) to indicate to the Service that the entity remains active.

This operation need only be used if the LIVELINESS setting is either MANUAL_BY_PARTICIPANT or MANUAL_BY_TOPIC. Otherwise, it has no effect.

NOTE: Writing data via the write operation on a DataWriter asserts liveliness on the DataWriter itself and its DomainParticipant. Consequently the use of assert_liveliness is only needed if the application is not writing data regularly.

Complete details are provided in 2.2.3.11, LIVELINESS.
2.2.4.2.23 get_matched_subscription_data

This operation retrieves information on a subscription that is currently “associated” with the DataWriter; that is, a subscription with a matching Topic and compatible QoS that the application has not indicated should be “ignored” by means of the DomainParticipant ignore_subscription operation.

The subscription_handle must correspond to a subscription currently associated with the DataWriter, otherwise the operation will fail and return BAD_PARAMETER. The operation get_matched_subscriptions can be used to find the subscriptions that are currently matched with the DataWriter.

The operation may also fail if the infrastructure does not hold the information necessary to fill in the subscription_data. In this case the operation will return UNSUPPORTED.

2.2.4.2.24 get_matched_subscriptions

This operation retrieves the list of subscriptions currently “associated” with the DataWriter; that is, subscriptions that have a matching Topic and compatible QoS that the application has not indicated should be “ignored” by means of the DomainParticipant ignore_subscription operation.

The handles returned in the ‘subscription_handles’ list are the ones that are used by the DDS implementation to locally identify the corresponding matched DataReader entities. These handles match the ones that appear in the ‘instance_handle’ field of the SampleInfo when reading the “DCPSSubscriptions” builtin topic.

The operation may fail if the infrastructure does not locally maintain the connectivity information.

2.2.4.3 PublisherListener Interface

<table>
<thead>
<tr>
<th>PublisherListener</th>

</tbody>
</table>

Since a Publisher is a kind of Entity, it has the ability to have a listener associated with it. In this case, the associated listener should be of concrete type PublisherListener. The use of this listener and its relationship to changes in the communication status of the Publisher is described in 2.2.4, Listeners, Conditions, and Wait-sets.
2.2.2.4.4 DataWriterListener Interface

<table>

Since a DataWriter is a kind of Entity, it has the ability to have a listener associated with it. In this case, the associated listener should be of concrete type DataWriterListener. The use of this listener and its relationship to changes in the communication status of the DataWriter is described in 2.2.4, Listeners, Conditions, and Wait-sets.

2.2.2.4.5 Concurrency Behavior

This specification makes no assumption about the way the publishing application is designed. In particular, several DataWriter may operate in different threads. If they share the same Publisher, the middleware guarantees that its operations are thread-safe. However, it is not required that each requesting thread be treated in isolation from the others (leading e.g., to several isolated sets of coherent changes). If this is the desired behavior, the proper design is to create a Publisher for each thread.
2.2.2.5 Subscription Module

Figure 2.10 - Class model of the DCPS Subscription Module
The Subscription Module is comprised of the following classifiers:

- Subscriber
- DataReader
- DataSample
- SampleInfo
- SubscriberListener
- DataReaderListener
- ReadCondition
- QueryCondition

The following sub clause presents how the data can be accessed and introduces the \textit{sample state}, \textit{view state}, and \textit{instance state}.

Sub clauses 2.2.2.5.2 (“Subscriber Class”) through 2.2.2.5.9 (“QueryCondition Class”) provide details on each class belonging to this module.

2.2.2.5.1 Access to the data

Data is made available to the application by the following operations on \texttt{DataReader} objects: \texttt{read}, \texttt{read\_w\_condition}, \texttt{take}, and \texttt{take\_w\_condition}. The general semantics of the “\texttt{read}” operations is that the application only gets access to the corresponding data\textsuperscript{14}; the data remains the middleware’s responsibility and can be read again. The semantics of the “\texttt{take}” operation is that the application takes full responsibility for the data; that data will no longer be accessible to the \texttt{DataReader}. Consequently, it is possible for a \texttt{DataReader} to access the same sample multiple times but only if all previous accesses were \texttt{read} operations.

Each of these operations returns an ordered collection of \texttt{Data} values and associated \texttt{SampleInfo} objects. Each data value represents an atom of data information (i.e., a value for one instance). This collection may contain samples related to the same or different instances (identified by the key). Multiple samples can refer to the same instance if the settings of the HISTORY QoS (2.2.3.18) allow for it.

2.2.2.5.1.1 Interpretation of the SampleInfo

The \texttt{SampleInfo} contains information pertaining to the associated \texttt{Data} value:

- The \texttt{sample state} of the \texttt{Data} value (i.e., if the sample has already been READ or NOT\_READ by that same \texttt{DataReader}).
- The \texttt{view state} of the related instance (i.e., if the instance is NEW, or NOT\_NEW for that \texttt{DataReader}) – see below.
- The \texttt{instance state} of the related instance (i.e., if the instance is ALIVE, NOT\_ALIVE\_DISPOSED, or NOT\_ALIVE\_NO\_WRITERS) – see below.
- The \texttt{valid data} flag. This flag indicates whether there is data associated with the sample. Some samples do not contain data indicating only a change on the \texttt{instance state} of the corresponding instance – see below.

\textsuperscript{14}Meaning a precise instance value.
• The values of \texttt{disposed\_generation\_count} and \texttt{no\_writers\_generation\_count} for the related instance at the time the sample was received. These counters indicate the number of times the instance had become ALIVE (with \texttt{instance\_state=ALIVE}) at the time the sample was received – see below.

• The \texttt{sample\_rank} and \texttt{generation\_rank} of the sample within the returned sequence. These ranks provide a preview of the samples that follow within the sequence returned by the \texttt{read} or \texttt{take} operations.

• The \texttt{absolute\_generation\_rank} of the sample within the DataReader. This rank provides a preview of what is available within the DataReader.

• The \texttt{source\_timestamp} of the sample. This is the timestamp provided by the DataWriter at the time the sample was produced.

2.2.2.5.1.2 Interpretation of the SampleInfo sample\_state

For each sample received, the middleware internally maintains a \texttt{sample\_state} relative to each DataReader. The \texttt{sample\_state} can either be \texttt{READ} or \texttt{NOT\_READ}.

• READ indicates that the DataReader has already accessed that sample by means of \texttt{read}^{15}.

• NOT\_READ indicates that the DataReader has not accessed that sample before.

The \texttt{sample\_state} will, in general, be different for each sample in the collection returned by \texttt{read} or \texttt{take}.

2.2.2.5.1.3 Interpretation of the SampleInfo instance\_state

For each instance the middleware internally maintains an \texttt{instance\_state}. The \texttt{instance\_state} can be ALIVE, NOT\_ALIVE\_DISPOSED or NOT\_ALIVE\_NO\_WRITERS.

• ALIVE indicates that (a) samples have been received for the instance, (b) there are live DataWriter entities writing the instance, and (c) the instance has not been explicitly disposed (or else more samples have been received after it was disposed).

• NOT\_ALIVE\_DISPOSED indicates the instance was explicitly disposed by a DataWriter by means of the \texttt{dispose} operation.

• NOT\_ALIVE\_NO\_WRITERS indicates the instance has been declared as not-alive by the DataReader because it detected that there are no live DataWriter entities writing that instance.

The precise behavior events that cause the \texttt{instance\_state} to change depends on the setting of the OWNERSHIP QoS:

• If OWNERSHIP is set to EXCLUSIVE, then the \texttt{instance\_state} becomes NOT\_ALIVE\_DISPOSED only if the DataWriter that “owns” the instance\textsuperscript{16} explicitly disposes it. The \texttt{instance\_state} becomes ALIVE again only if the DataWriter that owns the instance writes it.

• If OWNERSHIP is set to SHARED, then the \texttt{instance\_state} becomes NOT\_ALIVE\_DISPOSED if any DataWriter explicitly disposes the instance. The \texttt{instance\_state} becomes ALIVE as soon as any DataWriter writes the instance again.

\textsuperscript{15} Had the sample been accessed by \texttt{take} it would no longer be available to the DataReader.

\textsuperscript{16} The concept of “ownership” is described in 2.2.3.9.
The \textit{instance	extunderscore state} available in the \textit{SampleInfo} is a snapshot of the \textit{instance	extunderscore state} of the instance at the time the collection was obtained (i.e., at the time \texttt{read} or \texttt{take} was called). The \textit{instance	extunderscore state} is therefore the same for all samples in the returned collection that refer to the same instance.

2.2.2.5.1.4 Interpretation of the \textit{SampleInfo valid	extunderscore data}

Normally each \textit{DataSample} contains both a \textit{SampleInfo} and some Data. However there are situations where a \textit{DataSample} contains only the \textit{SampleInfo} and does not have any associated data. This occurs when the Service notifies the application of a change of state for an instance that was caused by some internal mechanism (such as a timeout) for which there is no associated data. An example of this situation is when the Service detects that an instance has no writers and changes the corresponding \textit{instance	extunderscore state} to \texttt{NOT	extunderscore ALIVE_NO_WRITERS}.

The actual set of scenarios under which the middleware returns DataSamples containing no Data is implementation dependent. The application can distinguish whether a particular \textit{DataSample} has data by examining the value of the \textit{valid	extunderscore data} flag. If this flag is set to TRUE, then the \textit{DataSample} contains data, if the flag is set to FALSE the \textit{DataSample} contains no Data.

To ensure correctness and portability, the \textit{valid	extunderscore data} flag must be examined by the application prior to accessing the Data associated with the \textit{DataSample} and if the flag is set to FALSE, the application should not access the Data associated with the \textit{DataSample}, that is, the application should access only the \textit{SampleInfo}.

2.2.2.5.1.5 Interpretation of the \textit{SampleInfo disposed	extunderscore generation	extunderscore count} and \textit{no	extunderscore writers	extunderscore generation	extunderscore count}

For each instance the middleware internally maintains two counts: the \textit{disposed	extunderscore generation	extunderscore count} and \textit{no	extunderscore writers	extunderscore generation	extunderscore count}, relative to each \textit{DataReader}:

- The \textit{disposed	extunderscore generation	extunderscore count} and \textit{no	extunderscore writers	extunderscore generation	extunderscore count} are initialized to zero when the \textit{DataReader} first detects the presence of a never-seen-before instance.
- The \textit{disposed	extunderscore generation	extunderscore count} is incremented each time the \textit{instance	extunderscore state} of the corresponding instance changes from \texttt{NOT	extunderscore ALIVE_DISPOSED} to \texttt{ALIVE}.
- The \textit{no	extunderscore writers	extunderscore generation	extunderscore count} is incremented each time the \textit{instance	extunderscore state} of the corresponding instance changes from \texttt{NOT	extunderscore ALIVE_NO_WRITERS} to \texttt{ALIVE}.

The \textit{disposed	extunderscore generation	extunderscore count} and \textit{no	extunderscore writers	extunderscore generation	extunderscore count} available in the \textit{SampleInfo} capture a snapshot of the corresponding counters at the time the sample was received.

2.2.2.5.1.6 Interpretation of the \textit{SampleInfo sample	extunderscore rank}, \textit{generation	extunderscore rank}, and \textit{absolute	extunderscore generation	extunderscore rank}

The \textit{sample	extunderscore rank} and \textit{generation	extunderscore rank} available in the \textit{SampleInfo} are computed based solely on the actual samples in the ordered collection returned by \texttt{read} or \texttt{take}.

- The \textit{sample	extunderscore rank} indicates the number of samples of the same instance that follow the current one in the collection.
- The \textit{generation	extunderscore rank} available in the \textit{SampleInfo} indicates the difference in ‘generations’ between the sample (S) and the Most Recent Sample of the same instance that appears in the returned Collection (MRSIC). That is, it counts the number of times the instance transitioned from not-alive to alive in the time from the reception of the S to the reception of MRSIC.

The \textit{generation	extunderscore rank} is computed using the formula:

\[
\text{generation	extunderscore rank} = \\
(MRSIC.\text{disposed	extunderscore generation	extunderscore count} + MRSIC.\text{no	extunderscore writers	extunderscore generation	extunderscore count}) \\
- (S.\text{disposed	extunderscore generation	extunderscore count} + S.\text{no	extunderscore writers	extunderscore generation	extunderscore count})
\]
The **absolute_generation_rank** available in the **SampleInfo** indicates the difference in ‘generations’ between the sample (S) and the Most Recent Sample of the same instance that the middleware has received (MRS). That is, it counts the number of times the instance transitioned from not-alive to alive in the time from the reception of the S to the time when the **read** or **take** was called.

\[
\text{absolute_generation_rank} = \\
(MRS\.disposed\_generation\_count + MRS\.no\_writers\_generation\_count) \\
- (S\.disposed\_generation\_count + S\.no\_writers\_generation\_count)
\]

### 2.2.2.5.1.7 Interpretation of the SampleInfo counters and ranks

These counters and ranks allow the application to distinguish samples belonging to different ‘generations’ of the instance. Note that it is possible for an instance to transition from not-alive to alive (and back) several times before the application accesses the data by means of **read** or **take**. In this case the returned collection may contain samples that cross generations (i.e., some samples were received before the instance became not-alive, other after the instance re-appeared again). Using the information in the **SampleInfo** the application can anticipate what other information regarding the same instance appears in the returned collection, as well as, in the infrastructure and thus make appropriate decisions. For example, an application desiring to only consider the most current sample for each instance would only look at samples with **sample_rank** == 0. Similarly an application desiring to only consider samples that correspond to the latest generation in the collection will only look at samples with **generation_rank** == 0. An application desiring only samples pertaining to the latest generation available will ignore samples for which **absolute_generation_rank** != 0. Other application-defined criteria may also be used.

### 2.2.2.5.1.8 Interpretation of the SampleInfo view state

For each instance (identified by the **key**), the middleware internally maintains a **view_state** relative to each **DataReader**. The **view_state** can either be **NEW** or **NOT_NEW**.

- **NEW** indicates that either this is the first time that the **DataReader** has ever accessed samples of that instance, or else that the **DataReader** has accessed previous samples of the instance, but the instance has since been reborn (i.e., become not-alive and then alive again). These two cases are distinguished by examining the **disposed_generation_count** and the **no_writers_generation_count**.

- **NOT_NEW** indicates that the **DataReader** has already accessed samples of the same instance and that the instance has not been reborn since.

The **view_state** available in the **SampleInfo** is a snapshot of the **view_state** of the instance relative to the **DataReader** used to access the samples at the time the collection was obtained (i.e., at the time **read** or **take** was called). The **view_state** is therefore the same for all samples in the returned collection that refer to the same instance.

Once an instance has been detected as not having any “live” writers and all the samples associated with the instance are ‘taken’ from the **DataReader**, the middleware can reclaim all local resources regarding the instance. Future samples will be treated as ‘never seen’.
2.2.2.5.1.9 Data access patterns

The application accesses data by means of the operations read or take on the DataReader. These operations return an ordered collection of DataSamples consisting of a SampleInfo part and a Data part. The way the middleware builds this collection depends on QoS policies set on the DataReader and Subscriber, as well as the source timestamp of the samples, and the parameters passed to the read/take operations, namely:

- The desired sample states (i.e., READ, NOT_READ, or both).
- The desired view states (i.e., NEW, NOT_NEW, or both).
- The desired instance states (ALIVE, NOT_ALIVE_DISPOSED, NOT_ALIVE_NO_WRITERS, or a combination of these).

The read and take operations are non-blocking and just deliver what is currently available that matches the specified states.

---

17. i.e., the data-samples that are parts of the list as well as their order.
The \texttt{read\_w\_condition} and \texttt{take\_w\_condition} operations take a \texttt{ReadCondition} object as a parameter instead of sample, view, and instance states. The behavior is that the samples returned will only be those for which the condition is TRUE. These operations, in conjunction with \texttt{ReadCondition} objects and a \texttt{WaitSet}, allow performing waiting reads (see below).

Once the data samples are available to the data readers, they can be read or taken by the application. The basic rule is that the application may do this in any order it wishes. This approach is very flexible and allows the application ultimate control. However, the application must use a specific access pattern in case it needs to retrieve samples in the proper order received, or it wants to access a complete set of coherent changes.

To access data coherently, or in order, the PRESENTATION QoS (explained in 2.2.3.6) must be set properly and the application must conform to the access pattern described below. Otherwise, the application will still access the data but will not necessarily see all coherent changes together, nor will it see the changes in the proper order.

There is a general pattern that will provide both ordered and coherent access across multiple \texttt{DataReader}s. This pattern will work for any settings of the PRESENTATION QoS. Simpler patterns may also work for specific settings of the QoS as described below.

1. **General pattern to access samples as a coherent set and/or in order across DataReader entities.** This case applies when PRESENTATION QoS specifies “\texttt{access\_scope=}GROUP.”
   - Upon notification to the \texttt{SubscriberListener} or following the similar \texttt{StatusCondition}\textsuperscript{18} enabled, the application uses \texttt{begin\_access} on the \texttt{Subscriber} to indicate it will be accessing data through the \texttt{Subscriber}.
   - Then it calls \texttt{get\_datareaders} on the \texttt{Subscriber} to get the list of \texttt{DataReader} objects where data samples are available.
   - Following this it calls \texttt{read} or \texttt{take} on each \texttt{DataReader} in the same order returned to access all the relevant changes in the \texttt{DataReader}.
   - Once it has called \texttt{read} or \texttt{take} on all the readers, it calls \texttt{end\_access}.

   Note that if the PRESENTATION QoS policy specifies \texttt{ordered\_access=}TRUE, then the list of \texttt{DataReader}s may return the same reader several times. In this manner the correct sample order can be maintained among samples in different \texttt{DataReader} objects.

2. **Specialized pattern if no order or coherence needs to be maintained across DataReader entities.** This case applies if PRESENTATION QoS policy specifies \texttt{access\_scope=something\_other\_than\_GROUP}.
   - In this case, it is not required for the application to call \texttt{begin\_access} and \texttt{end\_access}. However, doing so is not an error and it will have no effect.
   - The application accesses the data by calling \texttt{read} or \texttt{take}\textsuperscript{19} on each \texttt{DataReader} in any order it wishes.
   - The application can still call \texttt{get\_datareaders} to determine which readers have data to be read, but it does not need to read all of them, nor read them in a particular order. Furthermore, the return of \texttt{get\_datareaders} will be logically a “set” in the sense that the same reader will not appear twice, and the order of the readers returned is not specified.

3. **Specialized pattern if the application accesses the data within the SubscriberListener.** This case applies regardless of the PRESENTATION QoS policy when the application accesses the data inside the listener’s implementation of the \texttt{on\_data\_on\_readers} operation.

---

\textsuperscript{18}For instance, on \texttt{Subscriber} with mask referring to DATA\_ON\_READERS.
\textsuperscript{19}Or the variants \texttt{read\_w\_condition} and \texttt{take\_w\_condition}. 

• Similar to the previous case (2 above), it is not required for the application to call `begin_access` and `end_access`, but doing so has no effect.

• The application can access data by calling `read` or `take`\(^{20}\) on each `DataReader` in any order it wishes.

• The application can also delegate the accessing of the data to the `DataReaderListener` objects installed on each `DataReader` by calling `notify_datareaders`.

• Similar to the previous case (2 above), the application can still call `get_datareaders` to determine which readers have data to be read, but it does not need to read all of them, nor read them in a particular order. Furthermore, the return of `get_datareaders` will be logically a ‘set.’

**2.2.2.5.2 Subscriber Class**

A **Subscriber** is the object responsible for the actual reception of the data resulting from its subscriptions.

\(^{20}\) Or the variants `read_w_condition` and `take_w_condition`. 

A Subscriber acts on the behalf of one or several DataReader objects that are related to it. When it receives data (from the other parts of the system), it builds the list of concerned DataReader objects, and then indicates to the application that data is available, through its listener or by enabling related conditions. The application can access the list of concerned DataReader objects through the operation get_datareaders and then access the data available through operations on the DataReader.

All operations except for the base-class operations set_qos, get_qos, set_listener, get_listener, enable, get_statuscondition, and create_datareader may return the value NOT_ENABLED.

2.2.2.5.2.1 set_listener (from Entity)

By virtue of extending Entity, a Subscriber can be attached to a Listener at creation time or later by using the set_listener operation. The Listener attached must extend SubscriberListener. Listeners are described in 2.2.4, Listeners, Conditions, and Wait-sets.

2.2.2.5.2.2 get_listener (from Entity)

Allows access to the attached SubscriberListener.

2.2.2.5.2.3 set_qos (from Entity)

By virtue of extending Entity, a Subscriber can be given QoS at creation time or later by using the set_qos operation. See 2.2.3 for the list of QoS policies that may be set on a Subscriber.

Possible error codes returned in addition to the standard ones: IMMUTABLE_POLICY, INCONSISTENT_POLICY.

2.2.2.5.2.4 get_qos (from Entity)

Allows access to the values of the QoS.

2.2.2.5.2.5 create_datareader

This operation creates a DataReader. The returned DataReader will be attached and belong to the Subscriber.
The `DataReader` returned by the `create_datareader` operation will in fact be a derived class, specific to the data-type associated with the Topic. As described in 2.2.2.3.7, for each application-defined type “Foo” there is an implied auto-generated class `FooDataReader` that extends `DataReader` and contains the operations to read data of type “Foo.”

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

Note that a common application pattern to construct the QoS for the `DataReader` is to:

- Retrieve the QoS policies on the associated `Topic` by means of the `get_qos` operation on the `Topic`.
- Retrieve the default `DataReader` qos by means of the `get_default_datareader_qos` operation on the `Subscriber`.
- Combine those two QoS policies and selectively modify policies as desired.
- Use the resulting QoS policies to construct the `DataReader`.

The special value `DATAREADER_QOS_DEFAULT` can be used to indicate that the `DataReader` should be created with the default `DataReader` QoS set in the factory. The use of this value is equivalent to the application obtaining the default `DataReader` QoS by means of the operation `get_default_datareader_qos` (2.2.2.4.1.15) and using the resulting QoS to create the `DataReader`.

Provided that the `TopicDescription` passed to this method is a `Topic` or a `ContentFilteredTopic`, the special value `DATAREADER_QOS_USE_TOPIC_QOS` can be used to indicate that the `DataReader` should be created with a combination of the default `DataReader` QoS and the `Topic` QoS. (In the case of a `ContentFilteredTopic`, the Topic in question is the `ContentFilteredTopic`’s “related Topic.”) The use of this value is equivalent to the application obtaining the default `DataReader` QoS and the `Topic` QoS (by means of the operation `Topic::get_qos`) and then combining these two QoS using the operation `copy_from_topic_qos` whereby any policy that is set on the `Topic` QoS “overrides” the corresponding policy on the default QoS. The resulting QoS is then applied to the creation of the `DataReader`. It is an error to use `DATAREADER_QOS_USE_TOPIC_QOS` when creating a `DataReader` with a `MultiTopic`; this method will return a ‘nil’ value in that case.

The `TopicDescription` passed to this operation must have been created from the same `DomainParticipant` that was used to create this `Subscriber`. If the `TopicDescription` was created from a different `DomainParticipant`, the operation will fail and return a nil result.

2.2.2.5.2.6 delete_datareader

This operation deletes a `DataReader` that belongs to the `Subscriber`. If the `DataReader` does not belong to the `Subscriber`, the operation returns the error `PRECONDITION_NOT_MET`.

The deletion of a `DataReader` is not allowed if there are any existing `ReadCondition` or `QueryCondition` objects that are attached to the `DataReader`. If the `delete_datareader` operation is called on a `DataReader` with any of these existing objects attached to it, it will return `PRECONDITION_NOT_MET`.

The deletion of a `DataReader` is not allowed if it has any outstanding loans as a result of a call to `read`, `take`, or one of the variants thereof. If the `delete_datareader` operation is called on a `DataReader` with one or more outstanding loans, it will return `PRECONDITION_NOT_MET`.

The `delete_datareader` operation must be called on the same `Subscriber` object used to create the `DataReader`. If `delete_datareader` is called on a different `Subscriber`, the operation will have no effect and it will return `PRECONDITION_NOT_MET`.

Possible error codes returned in addition to the standard ones: `PRECONDITION_NOT_MET`. 

Data Distribution Service, v1.4
2.2.2.5.2.7 lookup_datareader

This operation retrieves a previously-created DataReader belonging to the Subscriber that is attached to a Topic with a matching topic_name. If no such DataReader exists, the operation will return ‘nil.’

If multiple DataReaders attached to the Subscriber satisfy this condition, then the operation will return one of them. It is not specified which one.

The use of this operation on the built-in Subscriber allows access to the built-in DataReader entities for the built-in topics21.

2.2.2.5.2.8 begin_access

This operation indicates that the application is about to access the data samples in any of the DataReader objects attached to the Subscriber.

The application is required to use this operation only if PRESENTATION QosPolicy of the Subscriber to which the DataReader belongs has the access_scope set to ‘GROUP.’

In the aforementioned case, the operation begin_access must be called prior to calling any of the sample-accessing operations, namely: get_datareaders on the Subscriber and read, take, read_w_condition, take_w_condition on any DataReader. Otherwise the sample-accessing operations will return the error PRECONDITION_NOT_MET. Once the application has finished accessing the data samples it must call end_access.

It is not required for the application to call begin_access/end_access if the PRESENTATION QosPolicy has the access_scope set to something other than ‘GROUP.’ Calling begin_access/end_access in this case is not considered an error and has no effect.

The calls to begin_access/end_access may be nested. In that case, the application must call end_access as many times as it called begin_access.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

2.2.2.5.2.9 end_access

Indicates that the application has finished accessing the data samples in DataReader objects managed by the Subscriber.

This operation must be used to ‘close’ a corresponding begin_access.

After calling end_access the application should no longer access any of the Data or SampleInfo elements returned from the sample-accessing operations. This call must close a previous call to begin_access otherwise the operation will return the error PRECONDITION_NOT_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

2.2.2.5.2.10 get_datareaders

This operation allows the application to access the DataReader objects that contain samples with the specified sample_states, view_states, and instance_states.

21. See 2.2.5 for more details on built-in topics.
If the PRESENTATION QosPolicy of the Subscriber to which the DataReader belongs has the access_scope set to ‘GROUP.’ This operation should only be invoked inside a begin_access/end_access block. Otherwise it will return the error PRECONDITION_NOT_MET.

Depending on the setting of the PRESENTATION QoS policy (see 2.2.3.6), the returned collection of DataReader objects may be a ‘set’ containing each DataReader at most once in no specified order, or a ‘list’ containing each DataReader one or more times in a specific order.

1. If PRESENTATION access_scope is INSTANCE or TOPIC the returned collection is a ‘set.’
2. If PRESENTATION access_scope is GROUP and ordered_access is set to TRUE, then the returned collection is a ‘list.’

This difference is due to the fact that, in the second situation it is required to access samples belonging to different DataReader objects in a particular order. In this case, the application should process each DataReader in the same order it appears in the ‘list’ and read or take exactly one sample from each DataReader. The patterns that an application should use to access data is fully described in 2.2.2.5.1, Access to the data.

2.2.2.5.2.11 notify_datareaders

This operation invokes the operation on_data_available on the DataReaderListener objects attached to contained DataReader entities with a DATA_AVAILABLE status that is considered changed as described in 2.2.4.2.2, Changes in Read Communication Statuses.

This operation is typically invoked from the on_data_on_readers operation in the SubscriberListener. That way the SubscriberListener can delegate to the DataReaderListener objects the handling of the data.

2.2.2.5.2.12 get_sample_lost_status

This operation allows access to the SAMPLE_LOST communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.2.13 get_participant

This operation returns the DomainParticipant to which the Subscriber belongs.

2.2.2.5.2.14 delete_contained_entities

This operation deletes all the entities that were created by means of the “create” operations on the Subscriber. That is, it deletes all contained DataReader objects. This pattern is applied recursively. In this manner the operation delete_contained_entities on the Subscriber will end up deleting all the entities recursively contained in the Subscriber, that is also the QueryCondition and ReadCondition objects belonging to the contained DataReaders.

The operation will return PRECONDITION_NOT_MET if any of the contained entities is in a state where it cannot be deleted. This will occur, for example, if a contained DataReader cannot be deleted because the application has called a read or take operation and has not called the corresponding return_loan operation to return the loaned samples.

Once delete_contained_entities returns successfully, the application may delete the Subscriber knowing that it has no contained DataReader objects.

2.2.2.5.2.15 set_default_datareader_qos

This operation sets a default value of the DataReader QoS policies which will be used for newly created DataReader entities in the case where the QoS policies are defaulted in the create_datareader operation.
This operation will check that the resulting policies are self consistent; if they are not, the operation will have no effect and return INCONSISTENT_POLICY.

The special value DATAREADER_QOS_DEFAULT may be passed to this operation to indicate that the default QoS should be reset back to the initial values the factory would use, that is the values that would be used if the set_default_datareader_qos operation had never been called.

2.2.2.5.2.16 get_default_datareader_qos

This operation retrieves the default value of the DataReader QoS, that is, the QoS policies which will be used for newly created DataReader entities in the case where the QoS policies are defaulted in the create_datareader operation.

The values retrieved get_default_datareader_qos will match the set of values specified on the last successful call to get_default_datareader_qos, or else, if the call was never made, the default values listed in the QoS table in 2.2.3, Supported QoS.

2.2.2.5.2.17 copy_from_topic_qos

This operation copies the policies in the a_topic_qos to the corresponding policies in the a_datareader_qos (replacing values in the a_datareader_qos, if present).

This is a “convenience” operation most useful in combination with the operations get_default_datareader_qos and Topic::get_qos. The operation copy_from_topic_qos can be used to merge the DataReader default QoS policies with the corresponding ones on the Topic. The resulting QoS can then be used to create a new DataReader, or set its QoS.

This operation does not check the resulting a_datareader_qos for consistency. This is because the ‘merged’ a_datareader_qos may not be the final one, as the application can still modify some policies prior to applying the policies to the DataReader.

2.2.2.5.3 DataReader Class

A DataReader allows the application (1) to declare the data it wishes to receive (i.e., make a subscription) and (2) to access the data received by the attached Subscriber.

```
A `DataReader` refers to exactly one `TopicDescription` (either a `Topic`, a `ContentFilteredTopic`, or a `MultiTopic`) that identifies the data to be read. The subscription has a unique resulting type. The data-reader may give access to several instances of the resulting type, which can be distinguished from each other by their `key` (as described in 2.2.1.2.2, Overall Conceptual Model).
**DataReader** is an abstract class. It must be specialized for each particular application data-type as shown in Figure 2.8. The additional methods that must be defined in the auto-generated class for a hypothetical application type “Foo” are shown in the table below:

</table>
All operations except for the base-class operations set_qos, get_qos, set_listener, get_listener, enable, and get_statuscondition may return the error NOT_ENABLED.

All sample-accessing operations, namely all variants of read, take may return the error PRECONDITION_NOT_MET. The circumstances that result on this are described in 2.2.2.5.2.8.

The following sub clauses give details on all the operations.

2.2.2.5.3.1 set_listener (from Entity)

By virtue of extending Entity, a DataReader can be attached to a Listener at creation time or later by using the set_listener operation. The Listener attached must extend DataReaderListener. Listeners are described in 2.2.4, Listeners, Conditions, and Wait-sets.

2.2.2.5.3.2 get_listener (from Entity)

Allows access to the attached DataReaderListener.

2.2.2.5.3.3 set_qos (from Entity)

By virtue of extending Entity, a DataReader can be given QoS at creation time or later by using the set_qos operation. See 2.2.3 for the list of QoS policies that may set on a DataReader.

Possible error codes returned in addition to the standard ones: IMMUTABLE_POLICY, INCONSISTENT_POLICY.

2.2.2.5.3.4 get_qos (from Entity)

Allows access to the values of the QoS.

2.2.2.5.3.5 create_readcondition

This operation creates a ReadCondition. The returned ReadCondition will be attached and belong to the DataReader.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

2.2.2.5.3.6 create_querycondition

This operation creates a QueryCondition. The returned QueryCondition will be attached and belong to the DataReader.
The syntax of the *query_expression* and *query_parameters* parameters is described in Annex B.

In case of failure, the operation will return a ‘nil’ value (as specified by the platform).

2.2.2.5.3.7 delete_readcondition

This operation deletes a *ReadCondition* attached to the DataReader. Since *QueryCondition* specializes *ReadCondition* it can also be used to delete a *QueryCondition*. If the *ReadCondition* is not attached to the *DataReader*, the operation will return the error PRECONDITION_NOT_MET.

Possible error codes returned in addition to the standard ones: PRECONDITION_NOT_MET.

2.2.2.5.3.8 read

This operation accesses a collection of *Data* values from the *DataReader*. The size of the returned collection will be limited to the specified *max_samples*. The properties of the *data_values* collection and the setting of the PRESENTATION QoS policy (see 2.2.3.6) may impose further limits on the size of the returned ‘list.’

1. If PRESENTATION *access_scope* is INSTANCE, then the returned collection is a ‘list’ where samples belonging to the same data-instance are consecutive.

2. If PRESENTATION *access_scope* is TOPIC and ordered_access is set to FALSE, then the returned collection is a ‘list’ where samples belonging to the same data-instance are consecutive.

3. If PRESENTATION *access_scope* is TOPIC and ordered_access is set to TRUE, then the returned collection is a ‘list’ where samples belonging to the same instance may or may not be consecutive. This is because to preserve order it may be necessary to mix samples from different instances.

4. If PRESENTATION *access_scope* is GROUP and ordered_access is set to FALSE, then the returned collection is a ‘list’ where samples belonging to the same data instance are consecutive.

5. If PRESENTATION *access_scope* is GROUP and ordered_access is set to TRUE, then the returned collection contains at most one sample. The difference in this case is due to the fact that it is required that the application is able to read samples belonging to different *DataReader* objects in a specific order.

In any case, the relative order between the samples of one instance is consistent with the DESTINATION_ORDER *QosPolicy*:

- If DESTINATION_ORDER is BY_RECEPTION_TIMESTAMP, samples belonging to the same instances will appear in the relative order in which they were received (FIFO, earlier samples ahead of the later samples).

- If DESTINATION_ORDER is BY_SOURCE_TIMESTAMP, samples belonging to the same instances will appear in the relative order implied by the *source_timestamp* (FIFO, smaller values of *source_timestamp* ahead of the larger values).

In addition to the collection of samples, the *read* operation also uses a collection of *SampleInfo* structures (*sample_infos*), see 2.2.2.5.5, SampleInfo Class.

The initial (input) properties of the *data_values* and *sample_infos* collections will determine the precise behavior of *read* operation. For the purposes of this description the collections are modeled as having three properties: the current-length (*len*), the maximum length (*max_len*), and whether the collection container owns the memory of the elements within (*owns*). PSM mappings that do not provide these facilities may need to change the signature of the *read* operation slightly to compensate for it.

The initial (input) values of the *len*, *max_len*, and *owns* properties for the *data_values* and *sample_infos* collections govern the behavior of the *read* operation as specified by the following rules:
1. The values of \( \text{len} \), \( \text{max_len} \), and \( \text{owns} \) for the two collections must be identical. Otherwise \textit{read} will and return \texttt{PRECONDITION\_NOT\_MET}.

2. On successful output, the values of \( \text{len} \), \( \text{max_len} \), and \( \text{owns} \) will be the same for both collections.

3. If the input \( \text{max_len} = 0 \), then the \textit{data_values} and \textit{sample_info} collections will be filled with elements that are ‘loaned’ by the \texttt{DataReader}. On output, \( \text{owns} \) will be \texttt{FALSE}, \( \text{len} \) will be set to the number of values returned, and \( \text{max_len} \) will be set to a value verifying \( \text{max_len} \geq \text{len} \). The use of this variant allows for zero-copy access to the data and the application will need to “return the loan” to the \texttt{DataWriter} using the \texttt{return\_loan} operation (see 2.2.2.5.3.20).

4. If the input \( \text{max_len}>0 \) and the input \( \text{owns} = \text{FALSE} \), then the \textit{read} operation will fail and return \texttt{PRECONDITION\_NOT\_MET}. This avoids the potential hard-to-detect memory leaks caused by an application forgetting to “return the loan.”

5. If input \( \text{max_len}>0 \) and the input \( \text{owns} = \text{TRUE} \), then the \textit{read} operation will copy the \textit{Data} values and \textit{SampleInfo} values into the elements already inside the collections. On output, \( \text{owns} \) will be \texttt{TRUE}, \( \text{len} \) will be set to the number of values copied, and \( \text{max_len} \) will remain unchanged. The use of this variant forces a copy but the application can control where the copy is placed and the application will not need to “return the loan.” The number of samples copied depends on the relative values of \( \text{max_len} \) and \( \text{max_samples} \):
   - If \( \text{max_samples} = \text{LENGTH\_UNLIMITED} \), then at most \( \text{max_len} \) values will be copied. The use of this variant lets the application limit the number of samples returned to what the sequence can accommodate.
   - If \( \text{max_samples} \leq \text{max_len} \), then at most \( \text{max_samples} \) values will be copied. The use of this variant lets the application limit the number of samples returned to fewer that what the sequence can accommodate.
   - If \( \text{max_samples} > \text{max_len} \), then the \textit{read} operation will fail and return \texttt{PRECONDITION\_NOT\_MET}. This avoids the potential confusion where the application expects to be able to access up to \( \text{max_samples} \), but that number can never be returned, even if they are available in the \texttt{DataReader}, because the output sequence cannot accommodate them.

As described above, upon return the \textit{data_values} and \textit{sample_info} collections may contain elements “loaned” from the \texttt{DataReader}. If this is the case, the application will need to use the \texttt{return\_loan} operation (see 2.2.2.5.3.20) to return the “loan” once it is no longer using the \textit{Data} in the collection. Upon return from \texttt{return\_loan}, the collection will have \( \text{max_len}=0 \) and \( \text{owns} = \text{FALSE} \).

The application can determine whether it is necessary to “return the loan” or not based on how the state of the collections when the \textit{read} operation was called, or by accessing the ‘owns’ property. However, in many cases it may be simpler to always call \texttt{return\_loan}, as this operation is harmless (i.e., leaves all elements unchanged) if the collection does not have a loan.

To avoid potential memory leaks, the implementation of the \texttt{Data} and \texttt{SampleInfo} collections should disallow changing the length of a collection for which \( \text{owns} = \text{FALSE} \). Furthermore, deleting a collection for which \( \text{owns} = \text{FALSE} \) should be considered an error.

On output, the collection of \texttt{Data} values and the collection of \texttt{SampleInfo} structures are of the same length and are in a one-to-one correspondence. Each \texttt{SampleInfo} provides information, such as the \texttt{source\_timestamp}, \texttt{sample\_state}, \texttt{view\_state}, and \texttt{instance\_state}, etc., about the corresponding sample.

Some elements in the returned collection may not have valid data. If the \texttt{instance\_state} in the \texttt{SampleInfo} is \texttt{NOT\_ALIVE\_DISPOSED} or \texttt{NOT\_ALIVE\_NO\_WRITERS}, then the last sample for that instance in the collection, that is,

22. Assuming the implementation supports it.
the one whose `SampleInfo` has `sample_rank==0` does not contain valid data. Samples that contain no data do not count towards the limits imposed by the `RESOURCE_LIMITS` QoS policy.

The act of reading a sample sets its `sample_state` to `READ`. If the sample belongs to the most recent generation of the instance, it will also set the `view_state` of the instance to `NOT_NEW`. It will not affect the `instance_state` of the instance.

This operation must be provided on the specialized class that is generated for the particular application data-type that is being read.

If the `DataReader` has no samples that meet the constraints, the return value will be `NO_DATA`.

### 2.2.2.5.3.9 take

This operation accesses a collection of data-samples from the `DataReader` and a corresponding collection of `SampleInfo` structures. The operation will return either a ‘list’ of samples or else a single sample. This is controlled by the `PRESENTATION QosPolicy` using the same logic as for the `read` operation (see 2.2.2.5.3.8).

The act of taking a sample removes it from the `DataReader` so it cannot be ‘read’ or ‘taken’ again. If the sample belongs to the most recent generation of the instance, it will also set the `view_state` of the instance to `NOT_NEW`. It will not affect the `instance_state` of the instance.

The behavior of the `take` operation follows the same rules than the `read` operation regarding the pre-conditions and post-conditions for the `data_values` and `sample_infos` collections. Similar to `read`, the `take` operation may ‘loan’ elements to the output collections which must then be returned by means of `return_loan`. The only difference with `read` is that, as stated, the sampled returned by take will no longer be accessible to successive calls to `read` or `take`.

Similar to `read`, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the `DataReader` has no samples that meet the constraints, the return value will be `NO_DATA`.

### 2.2.2.5.3.10 read_w_condition

This operation accesses via ‘read’ the samples that match the criteria specified in the `ReadCondition`. This operation is especially useful in combination with `QueryCondition` to filter data samples based on the content.

The specified `ReadCondition` must be attached to the `DataReader`; otherwise the operation will fail and return `PRECONDITION_NOT_MET`.

In case the `ReadCondition` is a ‘plain’ `ReadCondition` and not the specialized `QueryCondition`, the operation is equivalent to calling `read` and passing as `sample_states`, `view_states` and `instance_states` the value of the corresponding attributes in the `read_condition`. Using this operation the application can avoid repeating the same parameters specified when creating the `ReadCondition`.

The samples are accessed with the same semantics as the `read` operation.

Similar to `read`, this operation must be provided on the specialized class that is generated for the particular application data-type that is being read.

If the `DataReader` has no samples that meet the constraints, the return value will be `NO_DATA`.

### 2.2.2.5.3.11 take_w_condition

This operation is analogous to `read_w_condition` except it accesses samples via the ‘take’ operation.
The specified ReadCondition must be attached to the DataReader; otherwise the operation will fail and return PRECONDITION_NOT_MET.

The samples are accessed with the same semantics as the take operation.

This operation is especially useful in combination with QueryCondition to filter data samples based on the content.

Similar to take, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the DataReader has no samples that meet the constraints, the return value will be NO_DATA.

2.2.2.5.3.12 read_next_sample

This operation copies the next, non-previously accessed Data value from the DataReader; the operation also copies the corresponding SampleInfo. The implied order among the samples stored in the DataReader is the same as for the read operation (2.2.2.5.3.8).

The read_next_sample operation is semantically equivalent to the read operation where the input Data sequence has max_len=1, the sample_states=NOT_READ, the view_states=ANY_VIEW_STATE, and the instance_states=ANY_INSTANCE_STATE.

The read_next_sample operation provides a simplified API to ‘read’ samples avoiding the need for the application to manage sequences and specify states.

If there is no unread data in the DataReader, the operation will return NO_DATA and nothing is copied.

2.2.2.5.3.13 take_next_sample

This operation copies the next, non-previously accessed Data value from the DataReader and ‘removes’ it from the DataReader so it is no longer accessible. The operation also copies the corresponding SampleInfo. This operation is analogous to the read_next_sample except for the fact that the sample is ‘removed’ from the DataReader.

The take_next_sample operation is semantically equivalent to the take operation where the input sequence has max_len=1, the sample_states=NOT_READ, the view_states=ANY_VIEW_STATE, and the instance_states=ANY_INSTANCE_STATE.

This operation provides a simplified API to ‘take’ samples avoiding the need for the application to manage sequences and specify states.

If there is no unread data in the DataReader, the operation will return NO_DATA and nothing is copied.

2.2.2.5.3.14 read_instance

This operation accesses a collection of Data values from the DataReader. The behavior is identical to read except that all samples returned belong to the single specified instance whose handle is a_handle.

Upon successful return, the Data collection will contain samples all belonging to the same instance. The corresponding SampleInfo verifies instance_handle == a_handle.

The semantics are the same as for the read operation, except in building the collection the DataReader will check that the sample belongs to the specified instance and otherwise it will not place the sample in the returned collection.

The behavior of the read_instance operation follows the same rules as the read operation regarding the pre-conditions and post-conditions for the data_values and sample_infos collections. Similar to read, the read_instance operation may ‘loan’ elements to the output collections which must then be returned by means of return_loan.
Similar to read, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the DataReader has no samples that meet the constraints, the return value will be NO_DATA.

This operation may return BAD_PARAMETER if the InstanceHandle_t a_handle does not correspond to an existing data-object known to the DataReader. If the implementation is not able to check invalid handles, then the result in this situation is unspecified.

2.2.2.5.3.15 take_instance

This operation accesses a collection of Data values from the DataReader. The behavior is identical to take except for that all samples returned belong to the single specified instance whose handle is a_handle.

The semantics are the same as for the take operation, except in building the collection the DataReader will check that the sample belongs to the specified instance and otherwise it will not place the sample in the returned collection.

The behavior of the take_instance operation follows the same rules as the read operation regarding the pre-conditions and post-conditions for the data_values and sample_infos collections. Similar to read, the take_instance operation may ‘loan’ elements to the output collections which must then be returned by means of return_loan.

Similar to read, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the DataReader has no samples that meet the constraints, the return value will be NO_DATA.

This operation may return BAD_PARAMETER if the InstanceHandle_t a_handle does not correspond to an existing data-object known to the DataReader. If the implementation is not able to check invalid handles, then the result in this situation is unspecified.

2.2.2.5.3.16 read_next_instance

This operation accesses a collection of Data values from the DataReader where all the samples belong to a single instance. The behavior is similar to read_instance except that the actual instance is not directly specified. Rather the samples will all belong to the ‘next’ instance with instance_handle ‘greater’ than the specified previous_handle that has available samples.

This operation implies the existence of a total order ‘greater-than’ relationship between the instance handles. The specifics of this relationship are not all important and are implementation specific. The important thing is that, according to the middleware, all instances are ordered relative to each other. This ordering is between the instance handles: It should not depend on the state of the instance (e.g., whether it has data or not) and must be defined even for instance handles that do not correspond to instances currently managed by the DataReader. For the purposes of the ordering it should be ‘as if’ each instance handle was represented as a unique integer.

The behavior of read_next_instance is ‘as if’ the DataReader invoked read_instance passing the smallest instance_handle among all the ones that (a) are greater than previous_handle and (b) have available samples (i.e., samples that meet the constraints imposed by the specified states).

The special value HANDLE_NIL is guaranteed to be ‘less than’ any valid instance_handle. So the use of the parameter value previous_handle==HANDLE_NIL will return the samples for the instance which has the smallest instance_handle among all the instances that contain available samples.

23. according to some service-defined order.
The operation **read_next_instance** is intended to be used in an application-driven iteration where the application starts by passing `previous_handle` = HANDLE_NIL, examines the samples returned, and then uses the `instance_handle` returned in the `SampleInfo` as the value of the `previous_handle` argument to the next call to `read_next_instance`. The iteration continues until `read_next_instance` returns the value NO_DATA.

Note that it is possible to call the ‘`read_next_instance`’ operation with a `previous_handle` that does not correspond to an instance currently managed by the `DataReader`. This is because as stated earlier the ‘greater-than’ relationship is defined even for handles not managed by the `DataReader`. One practical situation where this may occur is when an application is iterating through all the instances, takes all the samples of a NOT_ALIVE_NO_WRITERS instance, returns the loan (at which point the instance information may be removed, and thus the handle becomes invalid), and tries to read the next instance.

The behavior of the **read_next_instance** operation follows the same rules than the **read** operation regarding the pre-conditions and post-conditions for the `data_values` and `sample_infos` collections. Similar to **read**, the **read_next_instance** operation may ‘loan’ elements to the output collections which must then be returned by means of `return_loan`.

Similar to **read**, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the **DataReader** has no samples that meet the constraints, the return value will be NO_DATA.

### 2.2.2.5.3.17 take_next_instance

This operation accesses a collection of `Data` values from the `DataReader` and ‘removes’ them from the `DataReader`.

This operation has the same behavior as **read_next_instance** except that the samples are ‘taken’ from the `DataReader` such that they are no longer accessible via subsequent ‘read’ or ‘take’ operations.

Similar to the operation **read_next_instance** (see 2.2.2.5.3.16) it is possible to call **take_next_instance** with a `previous_handle` that does not correspond to an instance currently managed by the `DataReader`.

The behavior of the **take_next_instance** operation follows the same rules as the **read** operation regarding the pre-conditions and post-conditions for the `data_values` and `sample_infos` collections. Similar to **read**, the **take_next_instance** operation may ‘loan’ elements to the output collections which must then be returned by means of `return_loan`.

Similar to **read**, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the **DataReader** has no samples that meet the constraints, the return value will be NO_DATA.

### 2.2.2.5.3.18 read_next_instance_w_condition

This operation accesses a collection of `Data` values from the `DataReader`. The behavior is identical to **read_next_instance** except that all samples returned satisfy the specified condition. In other words, on success all returned samples belong to the same instance, and the instance is the instance with ‘smallest’ `instance_handle` among the ones that verify (a) `instance_handle >= previous_handle` and (b) have samples for which the specified `ReadCondition` evaluates to TRUE.

Similar to the operation **read_next_instance** (see 2.2.2.5.3.16) it is possible to call **read_next_instance_w_condition** with a `previous_handle` that does not correspond to an instance currently managed by the `DataReader`.

The behavior of the **read_next_instance_w_condition** operation follows the same rules than the **read** operation regarding the pre-conditions and post-conditions for the `data_values` and `sample_infos` collections. Similar to **read**, the **read_next_instance_w_condition** operation may ‘loan’ elements to the output collections which must then be returned by means of `return_loan`. 
Similar to **read**, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the **DataReader** has no samples that meet the constraints, the return value will be NO_DATA.

### 2.2.2.5.3.19 take_next_instance_w_condition

This operation accesses a collection of **Data** values from the **DataReader** and ‘removes’ them from the **DataReader**.

This operation has the same behavior as **read_next_instance_w_condition** except that the samples are ‘taken’ from the **DataReader** such that they are no longer accessible via subsequent ‘read’ or ‘take’ operations.

Similar to the operation **read_next_instance** (see 2.2.2.5.16) it is possible to call **take_next_instance_w_condition** with a *previous_handle* that does not correspond to an instance currently managed by the **DataReader**.

The behavior of the **take_next_instance_w_condition** operation follows the same rules as the **read** operation regarding the pre-conditions and post-conditions for the **data_values** and **sample_infos** collections. Similar to **read**, the **take_next_instance_w_condition** operation may ‘loan’ elements to the output collections which must then be returned by means of **return_loan**.

Similar to **read**, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.

If the **DataReader** has no samples that meet the constraints, the return value will be NO_DATA.

### 2.2.2.5.3.20 return_loan

This operation indicates to the **DataReader** that the application is done accessing the collection of **data_values** and **sample_infos** obtained by some earlier invocation of **read** or **take** on the **DataReader**.

The **data_values** and **sample_infos** must belong to a single related ‘pair;’ that is, they should correspond to a pair returned from a single call to **read** or **take**. The **data_values** and **sample_infos** must also have been obtained from the same **DataReader** to which they are returned. If either of these conditions is not met, the operation will fail and return PRECONDITION_NOT_MET.

The operation **return_loan** allows implementations of the **read** and **take** operations to “loan” buffers from the **DataReader** to the application and in this manner provide “zero-copy” access to the data. During the loan, the **DataReader** will guarantee that the data and sample-information are not modified.

It is not necessary for an application to return the loans immediately after the **read** or **take** calls. However, as these buffers correspond to internal resources inside the **DataReader**, the application should not retain them indefinitely.

The use of the **return_loan** operation is only necessary if the **read** or **take** calls “loaned” buffers to the application. As described in 2.2.2.5.3.8 this only occurs if the **data_values** and **sample_infos** collections had max_len=0 at the time **read** or **take** was called. The application may also examine the ‘owns’ property of the collection to determine where there is an outstanding loan. However, calling **return_loan** on a collection that does not have a loan is safe and has no side effects.

If the collections had a loan, upon return from **return_loan** the collections will have max_len=0.

Similar to **read**, this operation must be provided on the specialized class that is generated for the particular application data-type that is being taken.
2.2.2.5.3.21 get_liveliness_changed_status

This operation allows access to the LIVELINESS_CHANGED communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.3.22 get_requested_deadline_missed_status

This operation allows access to the REQUESTED_DEADLINE_MISSED communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.3.23 get_requested_incompatible_qos_status

This operation allows access to the REQUESTED_INCOMPATIBLE_QOS communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.3.24 get_sample_lost_status

This operation allows access to the SAMPLE_LOST communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.3.25 get_sample_rejected_status

This operation allows access to the SAMPLE_REJECTED communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.3.26 get_subscription_matched_status

This operation allows access to the SUBSCRIPTION_MATCHED communication status. Communication statuses are described in 2.2.4.1.

2.2.2.5.3.27 get_topicdescription

This operation returns the TopicDescription associated with the DataReader. This is the same TopicDescription that was used to create the DataReader.

2.2.2.5.3.28 get_subscriber

This operation returns the Subscriber to which the DataReader belongs.

2.2.2.5.3.29 get_key_value

This operation can be used to retrieve the instance key that corresponds to an instance_handle. The operation will only fill the fields that form the key inside the key_holder instance.

This operation may return BAD_PARAMETER if the InstanceHandle_t a_handle does not correspond to an existing data-object known to the DataReader. If the implementation is not able to check invalid handles then the result in this situation is unspecified.

2.2.2.5.3.30 lookup_instance

This operation takes as a parameter an instance and returns a handle that can be used in subsequent operations that accept an instance handle as an argument. The instance parameter is only used for the purpose of examining the fields that define the key.
This operation does not register the instance in question. If the instance has not been previously registered, or if for any other reason the Service is unable to provide an instance handle, the Service will return the special value HANDLE_NIL.

2.2.2.5.3.31 delete_contained_entities

This operation deletes all the entities that were created by means of the “create” operations on the DataReader. That is, it deletes all contained ReadCondition and QueryCondition objects.

The operation will return PRECONDITION_NOT_MET if the any of the contained entities is in a state where it cannot be deleted.

Once delete_contained_entities returns successfully, the application may delete the DataReader knowing that it has no contained ReadCondition and QueryCondition objects.

2.2.2.5.3.32 wait_for_historical_data

This operation is intended only for DataReader entities that have a non-VOLATILE PERSISTENCE QoS kind.

As soon as an application enables a non-VOLATILE DataReader it will start receiving both “historical” data, i.e., the data that was written prior to the time the DataReader joined the domain, as well as any new data written by the DataWriter entities. There are situations where the application logic may require the application to wait until all “historical” data is received. This is the purpose of the wait_for_historical_data operation.

The operation wait_for_historical_data blocks the calling thread until either all “historical” data is received, or else the duration specified by the max_wait parameter elapses, whichever happens first. A return value of OK indicates that all the “historical” data was received; a return value of TIMEOUT indicates that max_wait elapsed before all the data was received.

2.2.2.5.3.33 get_matched_publication_data

This operation retrieves information on a publication that is currently “associated” with the DataReader; that is, a publication with a matching Topic and compatible QoS that the application has not indicated should be “ignored” by means of the DomainParticipant ignore_publication operation.

The publication_handle must correspond to a publication currently associated with the DataReader otherwise the operation will fail and return BAD_PARAMETER. The operation get_matched_publications can be used to find the publications that are currently matched with the DataReader.

The operation may also fail if the infrastructure does not hold the information necessary to fill in the publication_data. In this case the operation will return UNSUPPORTED.

2.2.2.5.3.34 get_matched_publications

This operation retrieves the list of publications currently “associated” with the DataReader; that is, publications that have a matching Topic and compatible QoS that the application has not indicated should be “ignored” by means of the DomainParticipant ignore_publication operation.

The handles returned in the ‘publication_handles’ list are the ones that are used by the DDS implementation to locally identify the corresponding matched DataWriter entities. These handles match the ones that appear in the ‘instance_handle’ field of the SampleInfo when reading the “DCPSPublications” builtin topic.

The operation may fail if the infrastructure does not locally maintain the connectivity information.
2.2.2.5.4 DataSample Class

A DataSample represents an atom of data information (i.e., one value for one instance) as returned by DataReader’s read/take operations. It consists of two parts: A SampleInfo and the Data.

2.2.2.5.5 SampleInfo Class

<table>
<thead>
<tr>
<th>SampleInfo</th>
</tr>
</thead>
<tbody>
<tr>
<td>attributes</td>
</tr>
<tr>
<td>sample_state</td>
</tr>
<tr>
<td>view_state</td>
</tr>
<tr>
<td>instance_state</td>
</tr>
<tr>
<td>disposed_generation_count</td>
</tr>
<tr>
<td>no_writers_generation_count</td>
</tr>
<tr>
<td>sample_rank</td>
</tr>
<tr>
<td>generation_rank</td>
</tr>
<tr>
<td>absolute_generation_rank</td>
</tr>
<tr>
<td>source_timestamp</td>
</tr>
<tr>
<td>instance_handle</td>
</tr>
<tr>
<td>publication_handle</td>
</tr>
<tr>
<td>valid_data</td>
</tr>
<tr>
<td>No operations</td>
</tr>
</tbody>
</table>

SampleInfo is the information that accompanies each sample that is ‘read’ or ‘taken.’ It contains the following information:

- The sample_state (READ or NOT_READ) - indicates whether or not the corresponding data sample has already been read.
- The view_state (NEW, or NOT_NEW) - indicates whether the DataReader has already seen samples for the most-current generation of the related instance.
- The instance_state (ALIVE, NOT_ALIVE_DISPOSED, or NOT_ALIVE_NO_WRITERS) - indicates whether the instance is currently in existence or, if it has been disposed, the reason why it was disposed.
  - ALIVE if this instance is currently in existence.
  - NOT_ALIVE_DISPOSED if this instance was disposed by a DataWriter.
  - NOT_ALIVE_NO_WRITERS if the instance has been disposed by the DataReader because none of the DataWriter objects currently “alive” (according to the LIVELINESS QoS) are writing the instance.
- The disposed_generation_count that indicates the number of times the instance had become alive after it was disposed explicitly by a DataWriter, at the time the sample was received.
- The no_writers_generation_count that indicates the number of times the instance had become alive after it was disposed because there were no writers, at the time the sample was received.
• The \textit{sample\_rank} that indicates the number of samples related to the same instance that follow in the collection returned by \textit{read} or \textit{take}.

• The \textit{generation\_rank} that indicates the generation difference (number of times the instance was disposed and become alive again) between the time the sample was received, and the time the most recent sample in the collection related to the same instance was received.

• The \textit{absolute\_generation\_rank} that indicates the generation difference (number of times the instance was disposed and become alive again) between the time the sample was received, and the time the most recent sample (which may not be in the returned collection) related to the same instance was received.

• the \textit{source\_timestamp} that indicates the time provided by the DataWriter when the sample was written.

• the \textit{instance\_handle} that identifies locally the corresponding instance.

• the \textit{publication\_handle} that identifies locally the \textit{DataWriter} that modified the instance. The \textit{publication\_handle} is the same \texttt{InstanceHandle\_t} that is returned by the operation \texttt{get\_matched\_publications} on the \textit{DataReader} and can also be used as a parameter to the \textit{DataReader} operation \texttt{get\_matched\_publication\_data}.

• the \textit{valid\_data} flag that indicates whether the \textit{DataSample} contains data or else it is only used to communicate of a change in the \textit{instance\_state} of the instance.

Refer to 2.2.2.5.1, Access to the data for a detailed explanation of these states and ranks.

\textbf{2.2.2.5.6 SubscriberListener Interface}

\begin{center}
\begin{tabular}{|c|c|}
\hline
\textit{SubscriberListener} & \\
\hline
no attributes & \\
\hline
operations & \\
\hline
\texttt{on\_data\_on\_readers} & \texttt{void} \\
\texttt{the\_subscriber} & \texttt{Subscriber} \\
\hline
\end{tabular}
\end{center}

Since a \textit{Subscriber} is a kind of \textit{Entity}, it has the ability to have an associated listener. In this case, the associated listener should be of concrete type \textit{SubscriberListener}. Its definition can be found in 2.2.4, Listeners, Conditions, and Wait-sets.
2.2.2.5.7 DataReaderListener Interface

<table>
<thead>
<tr>
<th><strong>DataReaderListener</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>on_data_available</td>
</tr>
<tr>

</tr>
<tr>
<td>the_reader</td>
</tr>
<tr>
<td>status</td>
</tr>
<tr>
<td>on_sample_lost</td>
</tr>
<tr>
<td>the_reader</td>
</tr>
<tr>
<td>status</td>
</tr>
</tbody>
</table>

Since a **DataReader** is a kind of **Entity**, it has the ability to have an associated listener. In this case, the associated listener should be of concrete type **DataReaderListener**. Its definition can be found in 2.2.4, Listeners, Conditions, and Wait-sets.

The operation **on_subscription_matched** is intended to inform the application of the discovery of **DataWriter** entities that match the **DataReader**. Some implementations of the service may not propagate this information. In that case the DDS specification does not require this listener operation to be called.

2.2.2.5.8 ReadCondition Class

**ReadCondition** objects are conditions specifically dedicated to read operations and attached to one **DataReader**.

<table>
<thead>
<tr>
<th><strong>ReadCondition</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>get_datareader</td>
</tr>
<tr>
<td>get_sample_state_mask</td>
</tr>
</tbody>
</table>
ReadCondition objects allow an application to specify the data samples it is interested in (by specifying the desired sample-states, view-states, and instance-states). See the parameter definitions for DataReader's read/take operations.) This allows the middleware to enable the condition only when suitable information is available. They are to be used in conjunction with a WaitSet as normal conditions. More than one ReadCondition may be attached to the same DataReader.

2.2.2.5.8.1 get_datareader

This operation returns the DataReader associated with the ReadCondition. Note that there is exactly one DataReader associated with each ReadCondition.

2.2.2.5.8.2 get_sample_state_mask

This operation returns the set of sample-states that are taken into account to determine the trigger_value of the ReadCondition. These are the sample-states specified when the ReadCondition was created.

2.2.2.5.8.3 get_view_state_mask

This operation returns the set of view-states that are taken into account to determine the trigger_value of the ReadCondition. These are the view-states specified when the ReadCondition was created.

2.2.2.5.8.4 get_instance_state_mask

This operation returns the set of instance-states that are taken into account to determine the trigger_value of the ReadCondition. These are the instance-states specified when the ReadCondition was created.

2.2.2.5.9 QueryCondition Class

QueryCondition objects are specialized ReadCondition objects that allow the application to also specify a filter on the locally available data.

<table>
<thead>
<tr>
<th>QueryCondition</th>
</tr>
</thead>
<tbody>
<tr>
<td>no attributes</td>
</tr>
<tr>
<td>operations</td>
</tr>
<tr>
<td>get_query_expression</td>
</tr>
<tr>
<td>get_query_parameters</td>
</tr>
<tr>
<td>out: query_parameters</td>
</tr>
<tr>
<td>set_query_parameters</td>
</tr>
<tr>
<td>query_parameters</td>
</tr>
</tbody>
</table>

24. For example, the application can specify that the condition must only be enabled when new instances are received by using the NEW view state.
The query (*query_expression*) is similar to an SQL WHERE clause and can be parameterized by arguments that are dynamically changeable by the *set_query_parameters* operation.

Precise syntax for the query expression can be found in Annex B.

This feature is optional. In the cases where it is not supported, the *DataReader::create_querycondition* will return a ‘nil’ value (as specified by the platform).

### 2.2.2.5.9.1 get_query_expression

This operation returns the *query_expression* associated with the *QueryCondition*. That is, the expression specified when the *QueryCondition* was created.

### 2.2.2.5.9.2 get_query_parameters

This operation returns the *query_parameters* associated with the *QueryCondition*. That is, the parameters specified on the last successful call to *set_query_parameters*, or if *set_query_parameters* was never called, the arguments specified when the *QueryCondition* was created.

### 2.2.2.5.9.3 set_query_parameters

This operation changes the *query_parameters* associated with the *QueryCondition*.

### 2.2.3  Supported QoS

The Data-Distribution Service (DDS) relies on the use of QoS. A QoS (Quality of Service) is a set of characteristics that controls some aspect of the behavior of the DDS Service. QoS is comprised of individual QoS policies (objects of type deriving from *QosPolicy*).
QoS (i.e., a list of QosPolicy objects) may be associated with all Entity objects in the system such as Topic, DataWriter, DataReader, Publisher, Subscriber, and DomainParticipant.
Some QosPolicy values may not be consistent with other ones. These cases are described in the table below. When a set of QosPolicy is passed (set_qos operations), the set resulting from adding the new policies on top of the previous is checked for consistency. If the resulting QoS is inconsistent, the change of QoS operation fails and the previous values are retained.

In several cases, for communications to occur properly (or efficiently), a QosPolicy on the publisher side must be compatible with a corresponding policy on the subscriber side. For example, if a Subscriber requests to receive data reliably while the corresponding Publisher defines a best-effort policy, communication will not happen as requested. To address this issue and maintain the desirable de-coupling of publication and subscription as much as possible, the specification for QosPolicy follows the subscriber-requested, publisher-offered pattern. In this pattern, the subscriber side can specify a “requested” value for a particular QosPolicy. The Publisher side specifies an “offered” value for that QosPolicy. The Service will then determine whether the value requested by the subscriber side is compatible with what is offered by the publisher side. If the two policies are compatible, then communication will be established. If the two policies are not compatible, the Service will not establish communications between the two Entity objects and will record this fact by means of the OFFERED_INCOMPATIBLE_QOS on the publisher end and REQUESTED_INCOMPATIBLE_QOS on the subscriber end (see 2.2.4.1). The application can detect this fact by means of a listener or conditions (see 2.2.4).

The QosPolicy objects that need to be set in a compatible manner between the publisher and subscriber ends are indicated by the setting of the ‘RxO’ property:

- An ‘RxO’ setting of “Yes” indicates that the policy can be set both at the publishing and subscribing ends and the values must be set in a compatible manner. In this case the compatible values are explicitly defined.
- An ‘RxO’ setting of “No” indicates that the policy can be set both at the publishing and subscribing ends but the two settings are independent. That is, all combinations of values are compatible.
- An ‘RxO’ setting of “N/A” indicates that the policy can only be specified at either the publishing or the subscribing end, but not at both ends. So compatibility does not apply.

The ‘changeable’ property determines whether the QosPolicy can be changed after the Entity is enabled. In other words, a policy with ‘changeable’ setting of ‘NO’ is considered “immutable” and can only be specified either at Entity creation time or else prior to calling the enable operation on the Entity.

The following tables give the list of supported QosPolicy: their name, semantics, possible values and the Entity they apply to.

<table>
<thead>

### PRESENTATION

An "access_scope": INSTANCE, TOPIC, GROUP

And two booleans: "coherent_access" "ordered_access"

Specifies how the samples representing changes to data instances are presented to the subscribing application.

This policy affects the application’s ability to specify and receive coherent changes and to see the relative order of changes. access_scope determines the largest scope spanning the entities for which the order and coherency of changes can be preserved. The two booleans control whether coherent access and ordered access are supported within the scope access_scope.

<table>
<thead>
<tr>
<th>Publisher, Subscriber</th>
<th>Yes</th>
<th>No</th>
</tr>
</thead>
</table>

### INSTANCE

Scope spans only a single instance.

Indicates that changes to one instance need not be coherent nor ordered with respect to changes to any other instance. In other words, order and coherent changes apply to each instance separately.

This is the default access_scope.

<table>
<thead>
<tr>
<th>TOPIC</th>
<th>Scope spans to all instances within the same DataWriter (or DataReader), but not across instances in different DataWriter (or DataReader).</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP</td>
<td>[optional] Scope spans to all instances belonging to DataWriter (or DataReader) entities within the same Publisher (or Subscriber).</td>
</tr>
<tr>

The purpose of this QoS is to allow the application to attach additional information to the created Entity objects such that when a remote application discovers their existence it can access that information and use it for its own purposes. One possible use of this QoS is to attach security credentials or some other information that can be used by the remote application to authenticate the source. In combination with operations such as ignore_participant, ignore_publication, ignore_subscription, and ignore_topic these QoS can assist an application to define and enforce its own security policies. The use of this QoS is not limited to security, rather it offers a simple, yet flexible extensibility mechanism.

1. Subject to timeouts that indicate loss of communication with a particular subscriber.
2. In practice this will be limited by the settings of the RESOURCE_LIMITS QoS.
3. Actually, the limit will then be set by the max_samples
4. Actually, the limit will then be set by the max_samples

### 2.2.3.1 USER_DATA

The purpose of this QoS is to allow the application to attach additional information to the created Entity objects such that when a remote application discovers their existence it can access that information and use it for its own purposes. One possible use of this QoS is to attach security credentials or some other information that can be used by the remote application to authenticate the source. In combination with operations such as ignore_participant, ignore_publication, ignore_subscription, and ignore_topic these QoS can assist an application to define and enforce its own security policies. The use of this QoS is not limited to security, rather it offers a simple, yet flexible extensibility mechanism.
2.2.3.2 TOPIC_DATA

The purpose of this QoS is to allow the application to attach additional information to the created Topic such that when a remote application discovers their existence it can examine the information and use it in an application-defined way. In combination with the listeners on the DataReader and DataWriter as well as by means of operations such as ignore_topic, these QoS can assist an application to extend the provided QoS.

2.2.3.3 GROUP_DATA

The purpose of this QoS is to allow the application to attach additional information to the created Publisher or Subscriber. The value of the GROUP_DATA is available to the application on the DataReader and DataWriter entities and is propagated by means of the built-in topics.

This QoS can be used by an application combination with the DataReaderListener and DataWriterListener to implement matching policies similar to those of the PARTITION QoS except the decision can be made based on an application-defined policy.

2.2.3.4 DURABILITY

The decoupling between DataReader and DataWriter offered by the Publish/Subscribe paradigm allows an application to write data even if there are no current readers on the network. Moreover, a DataReader that joins the network after some data has been written could potentially be interested in accessing the most current values of the data as well as potentially some history. This QoS policy controls whether the Service will actually make data available to late-joining readers. Note that although related, this does not strictly control what data the Service will maintain internally. That is, the Service may choose to maintain some data for its own purposes (e.g., flow control) and yet not make it available to late-joining readers if the DURABILITY QoS policy is set to VOLATILE.

The value offered is considered compatible with the value requested if and only if the inequality “offered kind >= requested kind” evaluates to ‘TRUE.’ For the purposes of this inequality, the values of DURABILITY kind are considered ordered such that VOLATILE < TRANSIENT_LOCAL < TRANSIENT < PERSISTENT.

For the purpose of implementing the DURABILITY QoS kind TRANSIENT or PERSISTENT, the service behaves “as if” for each Topic that has TRANSIENT or PERSISTENT DURABILITY kind there was a corresponding “built-in” DataReader and DataWriter configured to have the same DURABILITY kind. In other words, it is “as if” somewhere in the system (possibly on a remote node) there was a “built-in durability DataReader” that subscribed to that Topic and a “built-in durability DataWriter” that published that Topic as needed for the new subscribers that join the system.

For each Topic, the built-in fictitious “persistence service” DataReader and DataWriter has its QoS configured from the Topic QoS of the corresponding Topic. In other words, it is “as-if” the service first did find_topic to access the Topic, and then used the QoS from the Topic to configure the fictitious built-in entities.

A consequence of this model is that the transient or persistence serviced can be configured by means of setting the proper QoS on the Topic.

For a given Topic, the usual request/offered semantics apply to the matching between any DataWriter in the system that writes the Topic and the built-in transient/persistent DataReader for that Topic; similarly for the built-in transient/persistent DataWriter for a Topic and any DataReader for the Topic. As a consequence, a DataWriter that has an incompatible QoS with respect to what the Topic specified will not send its data to the transient/persistent service, and a DataReader that has an incompatible QoS with respect to the specified in the Topic will not get data from it.
Incompatibilities between local DataReader/DataReader entities and the corresponding fictitious “built-in transient/persistent entities” cause the REQUESTED_INCOMPATIBLE_QOS/OFFERED_INCOMPATIBLE_QOS status to change and the corresponding Listener invocations and/or signaling of Condition and WaitSet objects as they would with non-fictitious entities.

The setting of the service_cleanup_delay controls when the TRANSIENT or PERSISTENT service is able to remove all information regarding a data-instances. Information on a data-instances is maintained until the following conditions are met:

1. the instance has been explicitly disposed (instance_state = NOT_ALIVE_DISPOSED), and
2. while in the NOT_ALIVE_DISPOSED state the system detects that there are no more “live” DataWriter entities writing the instance, that is, all existing writers either unregister the instance (call unregister) or lose their liveliness, and
3. a time interval longer that service_cleanup_delay has elapsed since the moment the service detected that the previous two conditions were met.

The utility of the service_cleanup_delay is apparent in the situation where an application disposes an instance and it crashes before it has a chance to complete additional tasks related to the disposition. Upon re-start the application may ask for initial data to regain its state and the delay introduced by the service_cleanup_delay will allow the restarted application to receive the information on the disposed instance and complete the interrupted tasks.

2.2.3.5 DURABILITY_SERVICE

This policy is used to configure the HISTORY QoS and the RESOURCE_LIMITS QoS used by the fictitious DataReader and DataWriter used by the “persistence service.” The “persistence service” is the one responsible for implementing the DURABILITY kinds TRANSIENT and PERSISTENCE (see 2.2.3.4).

2.2.3.6 PRESENTATION

This QoS policy controls the extent to which changes to data-instances can be made dependent on each other and also the kind of dependencies that can be propagated and maintained by the Service.

The setting of coherent_access controls whether the Service will preserve the groupings of changes made by the publishing application by means of the operations begin_coherent_change and end_coherent_change.

The setting of ordered_access controls whether the Service will preserve the order of changes.

The granularity is controlled by the setting of the access_scope.

If coherent_access is set, then the access_scope controls the maximum extent of coherent changes. The behavior is as follows:

• If access_scope is set to INSTANCE, the use of begin_coherent_change and end_coherent_change has no effect on how the subscriber can access the data because with the scope limited to each instance, changes to separate instances are considered independent and thus cannot be grouped by a coherent change.

• If access_scope is set to TOPIC, then coherent changes (indicated by their enclosure within calls to begin_coherent_change and end_coherent_change) will be made available as such to each remote DataReader independently. That is, changes made to instances within each individual DataWriter will be available as coherent with respect to other changes to instances in that same DataWriter, but will not be grouped with changes made to instances belonging to a different DataWriter.

• If access_scope is set to GROUP, then coherent changes made to instances through a DataWriter attached to a common Publisher are made available as a unit to remote subscribers.
If ordered_access is set, then the access_scope controls the maximum extent for which order will be preserved by the Service.

- If access_scope is set to INSTANCE (the lowest level), then changes to each instance are considered unordered relative to changes to any other instance. That means that changes (creations, deletions, modifications) made to two instances are not necessarily seen in the order they occur. This is the case even if it is the same application thread making the changes using the same DataWriter.

- If access_scope is set to TOPIC, changes (creations, deletions, modifications) made by a single DataWriter are made available to subscribers in the same order they occur. Changes made to instances through different DataWriter entities are not necessarily seen in the order they occur. This is the case, even if the changes are made by a single application thread using DataWriter objects attached to the same Publisher.

- Finally, if access_scope is set to GROUP, changes made to instances via DataWriter entities attached to the same Publisher object are made available to subscribers on the same order they occur.

Note that this QoS policy controls the scope at which related changes are made available to the subscriber. This means the subscriber can access the changes in a coherent manner and in the proper order; however, it does not necessarily imply that the Subscriber will indeed access the changes in the correct order. For that to occur, the application at the subscriber end must use the proper logic in reading the DataReader objects, as described in 2.2.2.5.1, Access to the data.

The value offered is considered compatible with the value requested if and only if the following conditions are met:

1. The inequality “offered access_scope >= requested access_scope” evaluates to ‘TRUE.’ For the purposes of this inequality, the values of PRESENTATION access_scope are considered ordered such that INSTANCE < TOPIC < GROUP.

2. Requested coherent_access is FALSE, or else both offered and requested coherent_access are TRUE.

3. Requested ordered_access is FALSE, or else both offered and requested ordered _access are TRUE.

2.2.3.7 DEADLINE

This policy is useful for cases where a Topic is expected to have each instance updated periodically. On the publishing side this setting establishes a contract that the application must meet. On the subscribing side the setting establishes a minimum requirement for the remote publishers that are expected to supply the data values.

When the Service ‘matches’ a DataWriter and a DataReader it checks whether the settings are compatible (i.e., offered deadline period <= requested deadline period) if they are not, the two entities are informed (via the listener or condition mechanism) of the incompatibility of the QoS settings and communication will not occur.

Assuming that the reader and writer ends have compatible settings, the fulfillment of this contract is monitored by the Service and the application is informed of any violations by means of the proper listener or condition.

The value offered is considered compatible with the value requested if and only if the inequality “offered deadline period <= requested deadline period” evaluates to ‘TRUE.’

The setting of the DEADLINE policy must be set consistently with that of the TIME_BASED_FILTER. For these two policies to be consistent the settings must be such that “deadline period >= minimum_separation.”

2.2.3.8 LATENCY_BUDGET

This policy provides a means for the application to indicate to the middleware the “urgency” of the data-communication. By having a non-zero duration the Service can optimize its internal operation.
This policy is considered a hint. There is no specified mechanism as to how the service should take advantage of this hint. The value offered is considered compatible with the value requested if and only if the inequality “offered duration <= requested duration” evaluates to ‘TRUE.’

2.2.3.9 OWNERSHIP

This policy controls whether the Service allows multiple DataWriter objects to update the same instance (identified by Topic + key) of a data-object. There are two kinds of OWNERSHIP selected by the setting of the kind: SHARED and EXCLUSIVE.

2.2.3.9.1 SHARED kind

This setting indicates that the Service does not enforce unique ownership for each instance. In this case, multiple writers can update the same data-object instance. The subscriber to the Topic will be able to access modifications from all DataWriter objects, subject to the settings of other QoS that may filter particular samples (e.g., the TIME_BASED_FILTER or HISTORY QoS policy). In any case there is no “filtering” of modifications made based on the identity of the DataWriter that causes the modification.

2.2.3.9.2 EXCLUSIVE kind

This setting indicates that each instance of a data-object can only be modified by one DataWriter. In other words, at any point in time a single DataWriter "owns" each instance and is the only one whose modifications will be visible to the DataReader objects. The owner is determined by selecting the DataWriter with the highest value of the strength that is both “alive” as defined by the LIVELINESS QoS policy and has not violated its DEADLINE contract with regards to the data-instance. Ownership can therefore change as a result of (a) a DataWriter in the system with a higher value of the strength modifies the instance, (b) a change in the strength value of the DataWriter that owns the instance, (c) a change in the liveliness of the DataWriter that owns the instance, and (d) a deadline with regards to the instance that is missed by the DataWriter that owns the instance.

The behavior of the system is as if the determination was made independently by each DataReader. Each DataReader may detect the change of ownership at a different time. It is not a requirement that at a particular point in time all the DataReader objects for that Topic have a consistent picture of who owns each instance.

It is also not a requirement that the DataWriter objects are aware of whether they own a particular instance. There is no error or notification given to a DataWriter that modifies an instance it does not currently own.

The requirements are chosen to (a) preserve the decoupling of publishers and subscriber, and (b) allow the policy to be implemented efficiently.

It is possible that multiple DataWriter objects with the same strength modify the same instance. If this occurs the Service will pick one of the DataWriter objects as the “owner.” It is not specified how the owner is selected. However, it is required that the policy used to select the owner is such that all DataReader objects will make the same choice of the particular DataWriter that is the owner. It is also required that the owner remains the same until there is a change in strength, liveliness, the owner misses a deadline on the instance, a new DataWriter with higher strength modifies the instance, or another DataWriter with the same strength that is deemed by the Service to be the new owner modifies the instance.

26. The “strength” of a DataWriter is the value of its OWNERSHIP_STRENGTH QoS.
Exclusive ownership is on an instance-by-instance basis. That is, a subscriber can receive values written by a lower strength DataWriter as long as they affect instances whose values have not been set by the higher-strength DataWriter.

The value of the OWNERSHIP kind offered must exactly match the one requested or else they are considered incompatible.

2.2.3.10 OWNERSHIP_STRENGTH

This QoS policy should be used in combination with the OWNERSHIP policy. It only applies to the situation case where OWNERSHIP kind is set to EXCLUSIVE.

The value of the OWNERSHIP_STRENGTH is used to determine the ownership of a data-instance (identified by the key). The arbitration is performed by the DataReader. The rules used to perform the arbitration are described in 2.2.3.9.2, EXCLUSIVE kind.

2.2.3.11 LIVELINESS

This policy controls the mechanism and parameters used by the Service to ensure that particular entities on the network are still “alive.” The liveliness can also affect the ownership of a particular instance, as determined by the OWNERSHIP QoS policy.

This policy has several settings to support both data-objects that are updated periodically as well as those that are changed sporadically. It also allows customizing for different application requirements in terms of the kinds of failures that will be detected by the liveliness mechanism.

The AUTOMATIC liveliness setting is most appropriate for applications that only need to detect failures at the process-level\(^\text{27}\), but not application-logic failures within a process. The Service takes responsibility for renewing the leases at the required rates and thus, as long as the local process where a DomainParticipant is running and the link connecting it to remote participants remains connected, the entities within the DomainParticipant will be considered alive. This requires the lowest overhead.

The MANUAL settings (MANUAL_BY_PARTICIPANT, MANUAL_BY_TOPIC), require the application on the publishing side to periodically assert the liveliness before the lease expires to indicate the corresponding Entity is still alive. The action can be explicit by calling the assert_liveliness operations, or implicit by writing some data.

The two possible manual settings control the granularity at which the application must assert liveliness.

- The setting MANUAL_BY_PARTICIPANT requires only that one Entity within the publisher is asserted to be alive to deduce all other Entity objects within the same DomainParticipant are also alive.

- The setting MANUAL_BY_TOPIC requires that at least one instance within the DataWriter is asserted.

The value offered is considered compatible with the value requested if and only if the following conditions are met:

1. the inequality “offered kind >= requested kind” evaluates to ‘TRUE’. For the purposes of this inequality, the values of LIVELINESS kind are considered ordered such that:
   AUTOMATIC < MANUAL_BY_PARTICIPANT < MANUAL_BY_TOPIC.

\(^{27}\)Process here is used to mean an operating system-process as in an address space providing the context where a number of threads execute.
2. the inequality “offered \(lease\_duration\) <= requested \(lease\_duration\)” evaluates to TRUE.

Changes in LIVELINESS must be detected by the Service with a time-granularity greater or equal to the \(lease\_duration\). This ensures that the value of the \textit{LivelinessChangedStatus} is updated at least once during each \(lease\_duration\) and the related Listeners and \textit{WaitSets} are notified within a \(lease\_duration\) from the time the LIVELINESS changed.

2.2.3.12 TIME\_BASED\_FILTER

This policy allows a \textit{DataReader} to indicate that it does not necessarily want to see all values of each instance published under the \textit{Topic}. Rather, it wants to see at most one change every \textit{minimum\_separation} period.

The TIME\_BASED\_FILTER applies to each instance separately, that is, the constraint is that the \textit{DataReader} does not want to see more than one sample of each instance per \textit{minimum\_separation} period.

This setting allows a \textit{DataReader} to further decouple itself from the \textit{DataWriter} objects. It can be used to protect applications that are running on a heterogeneous network where some nodes are capable of generating data much faster than others can consume it. It also accommodates the fact that for fast-changing data different subscribers may have different requirements as to how frequently they need to be notified of the most current values.

The setting of a TIME\_BASED\_FILTER, that is, the selection of a \textit{minimum\_separation} with a value greater than zero is compatible with all settings of the HISTORY and RELIABILITY QoS. The TIME\_BASED\_FILTER specifies the samples that are of interest to the \textit{DataReader}. The HISTORY and RELIABILITY QoS affect the behavior of the middleware with respect to the samples that have been determined to be of interest to the \textit{DataReader}, that is, they apply after the TIME\_BASED\_FILTER has been applied.

In the case where the reliability QoS kind is RELIABLE then in steady-state, defined as the situation where the \textit{DataWriter} does not write new samples for a period “long” compared to the \textit{minimum\_separation}, the system should guarantee delivery the last sample to the \textit{DataReader}.

The setting of the TIME\_BASED\_FILTER \textit{minimum\_separation} must be consistent with the DEADLINE \textit{period}. For these two QoS policies to be consistent they must verify that "\textit{period} >= \textit{minimum\_separation}". An attempt to set these policies in an inconsistent manner when an entity is created of via a \texttt{set_qos} operation will cause the operation to fail.

2.2.3.13 PARTITION

This policy allows the introduction of a logical partition concept inside the ‘physical’ partition induced by a domain.

For a \textit{DataReader} to see the changes made to an instance by a \textit{DataWriter}, not only the \textit{Topic} must match, but also they must share a common partition. Each string in the list that defines this QoS policy defines a partition name. A partition name may contain wildcards. Sharing a common partition means that one of the partition names matches.

Failure to match partitions is not considered an “incompatible” QoS and does not trigger any listeners nor conditions.

This policy is changeable. A change of this policy can potentially modify the “match” of existing DataReader and DataWriter entities. It may establish new “matchs” that did not exist before, or break existing matchs.

PARTITION names can be regular expressions and include wildcards as defined by the POSIX fnmatch API (1003.2-1992 section B.6). Either \textit{Publisher} or \textit{Subscriber} may include regular expressions in partition names, but no two names that both contain wildcards will ever be considered to match. This means that although regular expressions may be used both at publisher as well as subscriber side, the service will not try to match two regular expressions (between publishers and subscribers).
Partitions are different from creating Entity objects in different domains in several ways. First, entities belonging to different domains are completely isolated from each other; there is no traffic, meta-traffic or any other way for an application or the Service itself to see entities in a domain it does not belong to. Second, an Entity can only belong to one domain whereas an Entity can be in multiple partitions. Finally, as far as the DDS Service is concerned, each unique data instance is identified by the tuple (domainId, Topic, key). Therefore two Entity objects in different domains cannot refer to the same data instance. On the other hand, the same data-instance can be made available (published) or requested (subscribed) on one or more partitions.

2.2.3.14 RELIABILITY

This policy indicates the level of reliability requested by a DataReader or offered by a DataWriter. These levels are ordered, BEST_EFFORT being lower than RELIABLE. A DataWriter offering a level is implicitly offering all levels below.

The setting of this policy has a dependency on the setting of the RESOURCE_LIMITS policy. In case the RELIABILITY kind is set to RELIABLE the write operation on the DataWriter may block if the modification would cause data to be lost or else cause one of the limits in specified in the RESOURCE_LIMITS to be exceeded. Under these circumstances, the RELIABILITY max_blocking_time configures the maximum duration the write operation may block.

If the RELIABILITY kind is set to RELIABLE, data-samples originating from a single DataWriter cannot be made available to the DataReader if there are previous data-samples that have not been received yet due to a communication error. In other words, the service will repair the error and re-transmit data-samples as needed in order to re-construct a correct snapshot of the DataWriter history before it is accessible by the DataReader.

If the RELIABILITY kind is set to BEST_EFFORT, the service will not re-transmit missing data-samples. However for data-samples originating from any one DataWriter the service will ensure they are stored in the DataReader history in the same order they originated in the DataWriter. In other words, the DataReader may miss some data-samples but it will never see the value of a data-object change from a newer value to an order value.

The value offered is considered compatible with the value requested if and only if the inequality “offered kind >= requested kind” evaluates to ‘TRUE.’ For the purposes of this inequality, the values of RELIABILITY kind are considered ordered such that BEST_EFFORT < RELIABLE.

2.2.3.15 TRANSPORT_PRIORITY

The purpose of this QoS is to allow the application to take advantage of transports capable of sending messages with different priorities.

This policy is considered a hint. The policy depends on the ability of the underlying transports to set a priority on the messages they send. Any value within the range of a 32-bit signed integer may be chosen; higher values indicate higher priority. However, any further interpretation of this policy is specific to a particular transport and a particular implementation of the Service. For example, a particular transport is permitted to treat a range of priority values as equivalent to one another. It is expected that during transport configuration the application would provide a mapping between the values of the TRANSPORT_PRIORITY set on DataWriter and the values meaningful to each transport. This mapping would then be used by the infrastructure when propagating the data written by the DataWriter.

2.2.3.16 LIFESPAN

The purpose of this QoS is to avoid delivering “stale” data to the application.

Each data sample written by the DataWriter has an associated ‘expiration time’ beyond which the data should not be delivered to any application. Once the sample expires, the data will be removed from the DataReader caches as well as from the transient and persistent information caches.
The ‘expiration time’ of each sample is computed by adding the duration specified by the LIFESPAN QoS to the source timestamp. As described in 2.2.2.4.2.11 and 2.2.2.4.2.12 the source timestamp is either automatically computed by the Service each time the DataWriter write operation is called, or else supplied by the application by means of the write_w_timestamp operation.

This QoS relies on the sender and receiving applications having their clocks sufficiently synchronized. If this is not the case and the Service can detect it, the DataReader is allowed to use the reception timestamp instead of the source timestamp in its computation of the ‘expiration time.’

2.2.3.17 DESTINATION_ORDER

This policy controls how each subscriber resolves the final value of a data instance that is written by multiple DataWriter objects (which may be associated with different Publisher objects) running on different nodes.

The setting BY_RECEPTION_TIMESTAMP indicates that, assuming the OWNERSHIP policy allows it, the latest received value for the instance should be the one whose value is kept. This is the default value.

The setting BY_SOURCE_TIMESTAMP indicates that, assuming the OWNERSHIP policy allows it, a timestamp placed at the source should be used. This is the only setting that, in the case of concurrent same-strength DataWriter objects updating the same instance, ensures all subscribers will end up with the same final value for the instance. The mechanism to set the source timestamp is middleware dependent.

The value offered is considered compatible with the value requested if and only if the inequality “offered kind \( \geq \) requested kind” evaluates to ‘TRUE.’ For the purposes of this inequality, the values of DESTINATION_ORDER kind are considered ordered such that BY_RECEPTION_TIMESTAMP < BY_SOURCE_TIMESTAMP.

2.2.3.18 HISTORY

1. This policy controls the behavior of the Service when the value of an instance changes before it is finally communicated to some of its existing DataReader entities.

2. If the kind is set to KEEP_LAST, then the Service will only attempt to keep the latest values of the instance and discard the older ones. In this case, the value of depth regulates the maximum number of values (up to and including the most current one) the Service will maintain and deliver. The default (and most common setting) for depth is one, indicating that only the most recent value should be delivered.

3. If the kind is set to KEEP_ALL, then the Service will attempt to maintain and deliver all the values of the instance to existing subscribers. The resources that the Service can use to keep this history are limited by the settings of the RESOURCE_LIMITS QoS. If the limit is reached, then the behavior of the Service will depend on the RELIABILITY QoS. If the reliability kind is BEST_EFFORT, then the old values will be discarded. If reliability is RELIABLE, then the Service will block the DataWriter until it can deliver the necessary old values to all subscribers.

The setting of HISTORY depth must be consistent with the RESOURCE_LIMITS max_samples_per_instance. For these two QoS to be consistent, they must verify that depth \( \leq \) max_samples_per_instance.

2.2.3.19 RESOURCE_LIMITS

This policy controls the resources that the Service can use in order to meet the requirements imposed by the application and other QoS settings.
If the DataWriter objects are communicating samples faster than they are ultimately taken by the DataReader objects, the middleware will eventually hit against some of the QoS-imposed resource limits. Note that this may occur when just a single DataReader cannot keep up with its corresponding DataWriter. The behavior in this case depends on the setting for the RELIABILITY QoS. If reliability is BEST_EFFORT then the Service is allowed to drop samples. If the reliability is RELIABLE, the Service will block the DataWriter or discard the sample at the DataReader 28 in order not to lose existing samples.

The constant LENGTH_UNLIMITED may be used to indicate the absence of a particular limit. For example setting max_samples_per_instance to LENGTH_UNLIMITED will cause the middleware to not enforce this particular limit.

The setting of RESOURCE_LIMITS max_samples must be consistent with the max_samples_per_instance. For these two values to be consistent they must verify that “max_samples >= max_samples_per_instance.”

The setting of RESOURCE_LIMITS max_samples_per_instance must be consistent with the HISTORY depth. For these two QoS to be consistent, they must verify that “depth <= max_samples_per_instance.”

An attempt to set this policy to inconsistent values when an entity is created of via a set_qos operation will cause the operation to fail.

2.2.3.20 ENTITY_FACTORY

This policy controls the behavior of the Entity as a factory for other entities.

This policy concerns only DomainParticipant (as factory for Publisher, Subscriber, and Topic), Publisher (as factory for DataWriter), and Subscriber (as factory for DataReader).

This policy is mutable. A change in the policy affects only the entities created after the change; not the previously created entities.

The setting of autoenable_created_entities to TRUE indicates that the factory create_<entity> operation will automatically invoke the enable operation each time a new Entity is created. Therefore, the Entity returned by create_<entity> will already be enabled. A setting of FALSE indicates that the Entity will not be automatically enabled. The application will need to enable it explicitly by means of the enable operation (see 2.2.2.1.1.7).

The default setting of autoenable_created_entities = TRUE means that, by default, it is not necessary to explicitly call enable on newly created entities.

2.2.3.21 WRITER_DATA_LIFECYCLE

This policy controls the behavior of the DataWriter with regards to the lifecycle of the data-instances it manages, that is, the data-instances that have been either explicitly registered with the DataWriter using the register operations (see 2.2.2.4.2.5 and 2.2.2.4.2.6) or implicitly by directly writing the data (see 2.2.2.4.2.11 and 2.2.2.4.2.12).

The autodispose_unregistered_instances flag controls the behavior when the DataWriter unregisters an instance by means of the unregister operations (see 2.2.2.4.2.7 and 2.2.2.4.2.8):

- The setting ‘autodispose_unregistered_instances = TRUE’ causes the DataWriter to dispose the instance each time it is unregistered. The behavior is identical to explicitly calling one of the dispose operations (2.2.2.4.2.13 and 2.2.2.4.2.14) on the instance prior to calling the unregister operation.

28. So that the sample can be re-sent at a later time.
• The setting ‘autodispose_unregistered_instances = FALSE’ will not cause this automatic disposition upon unregistering. The application can still call one of the dispose operations prior to unregistering the instance and accomplish the same effect. Refer to 2.2.3.23.3 for a description of the consequences of disposing and unregistering instances.

Note that the deletion of a DataWriter automatically unregisters all data-instances it manages (2.2.4.1.6). Therefore the setting of the autodispose_unregistered_instances flag will determine whether instances are ultimately disposed when the DataWriter is deleted either directly by means of the Publisher::delete_datawriter operation or indirectly as a consequence of calling delete_contained_entities on the Publisher or the DomainParticipant that contains the DataWriter.

2.2.3.22 READER_DATA_LIFECYCLE

This policy controls the behavior of the DataReader with regards to the lifecycle of the data-instances it manages, that is, the data-instances that have been received and for which the DataReader maintains some internal resources.

The DataReader internally maintains the samples that have not been taken by the application, subject to the constraints imposed by other QoS policies such as HISTORY and RESOURCE_LIMITS.

The DataReader also maintains information regarding the identity, view_state and instance_state of data-instances even after all samples have been ‘taken.’ This is needed to properly compute the states when future samples arrive.

Under normal circumstances the DataReader can only reclaim all resources for instances for which there are no writers and for which all samples have been ‘taken.’ The last sample the DataReader will have taken for that instance will have an instance_state of either NOT_ALIVE_NO_WRITERS or NOT_ALIVE_DISPOSED depending on whether the last writer that had ownership of the instance disposed it or not. Refer to Figure 2.11 for a statechart describing the transitions possible for the instance_state. In the absence of the READER_DATA_LIFECYCLE QoS this behavior could cause problems if the application ‘forgets’ to ‘take’ those samples. The ‘untaken’ samples will prevent the DataReader from reclaiming the resources and they would remain in the DataReader indefinitely.

The autopurge_nowriter_samples_delay defines the maximum duration for which the DataReader will maintain information regarding an instance once its instance_state becomes NOT_ALIVE_NO_WRITERS. After this time elapses, the DataReader will purge all internal information regarding the instance, any untaken samples will also be lost.

The autopurge_disposed_samples_delay defines the maximum duration for which the DataReader will maintain samples for an instance once its instance_state becomes NOT_ALIVE_DISPOSED. After this time elapses, the DataReader will purge all samples for the instance.

2.2.3.23 Relationship between registration, LIVELINESS, and OWNERSHIP

The need for registering/unregistering instances stems from two use cases:

• Ownership resolution on redundant systems.

• Detection of loss in topological connectivity.

These two use cases also illustrate the semantic differences between the unregister_instance and dispose operations on a DataWriter.

2.2.3.23.1 Ownership resolution on redundant systems

It is expected that users may use DDS to set up redundant systems where multiple DataWriter entities are “capable” of writing the same instance. In this situation the DataWriter entities are configured such that:
Either both are writing the instance “constantly,”

or else they use some mechanism to classify each other as “primary” and “secondary,” such that the primary is the only one writing, and the secondary monitors the primary and only writes when it detects that the primary “writer” is no longer writing.

Both cases above use the OWNERSHIP policy kind EXCLUSIVE and arbitrate themselves by means of the OWNERSHIP_STRENGTH. Regardless of the scheme, the desired behavior from the DataReader point of view is that reader normally receives data from the primary unless the “primary” writer stops writing in which case the reader starts to receive data from the secondary DataWriter.

This approach requires some mechanism to detect that a DataWriter (the primary) is no longer “writing” the data as it should. There are several reasons why this may be happening and all must be detected but not necessarily distinguished:

1. [crash] - The writing process is no longer running (e.g., the whole application has crashed).
2. [connectivity loss] - Connectivity to the writing application has been lost (e.g., network got disconnected).
3. [application fault] - The application logic that was writing the data is faulty and has stopped calling the “write” operation on the DataWriter.

Arbitrating from a DataWriter to one of a higher strength is simple and the decision can be taken autonomously by the DataReader. Switching ownership from a higher strength DataWriter to one of a lower strength DataWriter requires that the DataReader can make a determination that the stronger DataWriter is “no longer writing the instance.”

2.2.3.23.1.1 Case where the data is periodically updated

This determination is reasonably simple when the data is being written periodically at some rate. The DataWriter simply states its offered DEADLINE (maximum interval between updates) and the DataReader automatically monitors that the DataWriter indeed updates the instance at least once per deadline period. If the deadline is missed, the DataReader considers the DataWriter “not alive” and automatically gives ownership to the next highest-strength DataWriter that is alive.

2.2.3.23.1.2 Case where data is not periodically updated

The case where the DataWriter is not writing data periodically is also a very important use-case. Since the instance is not being updated at any fixed period, the “deadline” mechanism cannot be used to determine ownership. The liveliness solves this situation. Ownership is maintained while the DataWriter is “alive” and for the DataWriter to be alive it must fulfill its “LIVELINESS” QoS contract. The different means to renew liveliness (automatic, manual) combined by the implied renewal each time data is written handle the three conditions above [crash], [connectivity loss], and [application fault]. Note that to handle [application fault] LIVELINESS must be MANUAL_BY_TOPIC. The DataWriter can retain ownership by periodically writing data or else calling assert_liveliness if it has no data to write. Alternatively if only protection against [crash] or [connectivity loss] is desired, it is sufficient that some task on the writer process periodically writes data or calls assert_liveliness on the DomainParticipant.

However, this scenario requires that the DataReader knows what instances are being “written” by the DataWriter. That is the only way that the DataReader deduces the ownership of specific instances from the fact that the DataWriter is still “alive.” Hence the need for the writer to “register” and “unregister” instances. Note that while “registration” can be done lazily the first time the DataWriter writes the instance, “unregistration” in general cannot. Similar reasoning will lead to the fact that unregistration will also require a message to be sent to the readers.
2.2.3.23.2 Detection of loss in topological connectivity

There are applications that are designed in such a way that their correct operation requires some minimal topological connectivity, that is, the writer needs to have a minimum number of readers or alternatively the reader must have a minimum number of writers.

A common scenario is that the application does not start doing its logic until it knows that some specific writers have the minimum configured readers (e.g., the alarm monitor is up).

A more common scenario is that the application logic will wait until some writers appear that can provide some needed source of information (e.g., the raw sensor data that must be processed).

Furthermore once the application is running it is a requirement that this minimal connectivity (from the source of the data) is monitored and the application informed if it is ever lost. For the case where data is being written periodically, the DEADLINE QoS and the on_deadline_missed listener provides the notification. The case where data is not periodically updated requires the use of the LIVELINESS in combination with register/unregister instance to detect whether the “connectivity” has been lost, and the notification is provided by means of the “NO_WRITERS” view state.

In terms of the required mechanisms the scenario is very similar to the case of maintaining ownership. In both cases the reader needs to know whether a writer is still “managing the current value of an instance” even though it is not continually writing it and this knowledge requires the writer to keep its liveliness plus some means to know which instances the writer is currently “managing” (i.e., the registered instances).

2.2.3.23.3 Semantic difference between unregister_instance and dispose

The DataWriter operation dispose is semantically different from unregister_instance. The dispose operation indicates that the data-instance no longer exists (e.g., a track that has disappeared, a simulation entity that has been destroyed, a record entry that has been deleted, etc.) whereas the unregister_instance operation indicates that the writer is no longer taking responsibility for updating the value of the instance.

Deleting a DataWriter is equivalent to unregistering all the instances it was writing, but is not the same as “disposing” all the instances.

For a Topic with EXCLUSIVE OWNERSHIP if the current owner of an instance disposes it, the readers accessing the instance will see the instance_state as being “DISPOSED” and not see the values being written by the weaker writer (even after the stronger one has disposed the instance). This is because the DataWriter that owns the instance is saying that the instance no longer exists (e.g., the master of the database is saying that a record has been deleted) and thus the readers should see it as such.

For a Topic with EXCLUSIVE OWNERSHIP if the current owner of an instance unregisters it, then it will relinquish ownership of the instance and thus the readers may see the value updated by another writer (which will then become the owner). This is because the owner said that it no longer will be providing values for the instance and thus another writer can take ownership and provide those values.

2.2.4 Listeners, Conditions, and Wait-sets

Listeners and conditions (in conjunction with wait-sets) are two alternative mechanisms that allow the application to be made aware of changes in the DCPS communication status.
### 2.2.4.1 Communication Status

The communication statuses whose changes can be communicated to the application depend on the **Entity**. The following table shows for each entity the statuses that are relevant.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Status Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Topic</td>
<td>INCONSISTENT_TOPIC</td>
<td>Another topic exists with the same name but different characteristics.</td>
</tr>
<tr>
<td>Subscriber</td>
<td>DATA_ON_READERS</td>
<td>New information is available.</td>
</tr>
<tr>
<td>DataReader</td>
<td>SAMPLE_REJECTED</td>
<td>A (received) sample has been rejected.</td>
</tr>
<tr>
<td></td>
<td>LIVELINESS_CHANGED</td>
<td>The liveness of one or more DataWriter that were writing instances read through the DataReader has changed. Some DataWriter have become “active” or “inactive.”</td>
</tr>
<tr>
<td></td>
<td>REQUESTED_DEADLINE_MISSED</td>
<td>The deadline that the DataReader was expecting through its QosPolicy DEADLINE was not respected for a specific instance.</td>
</tr>
<tr>
<td></td>
<td>REQUESTED_INCOMPATIBLE_QOS</td>
<td>A QosPolicy value was incompatible with what is offered.</td>
</tr>
<tr>
<td></td>
<td>DATA_AVAILABLE</td>
<td>New information is available.</td>
</tr>
<tr>
<td></td>
<td>SAMPLE_LOST</td>
<td>A sample has been lost (never received).</td>
</tr>
<tr>
<td></td>
<td>SUBSCRIPTION_MATCHED</td>
<td>The DataReader has found a DataWriter that matches the Topic and has compatible QoS, or has ceased to be matched with a DataWriter that was previously considered to be matched.</td>
</tr>
<tr>
<td>DataWriter</td>
<td>LIVELINESS_LOST</td>
<td>The liveness that the DataWriter has committed through its QosPolicy LIVELINESS was not respected; thus DataReader entities will consider the DataWriter as no longer “active.”</td>
</tr>
<tr>
<td></td>
<td>OFFERED_DEADLINE_MISSED</td>
<td>The deadline that the DataWriter has committed through its QosPolicy DEADLINE was not respected for a specific instance.</td>
</tr>
<tr>
<td></td>
<td>OFFERED_INCOMPATIBLE_QOS</td>
<td>A QosPolicy value was incompatible with what was requested.</td>
</tr>
<tr>
<td></td>
<td>PUBLICATION_MATCHED</td>
<td>The DataWriter has found DataReader that matches the Topic and has compatible QoS, or has ceased to be matched with a DataReader that was previously considered to be matched.</td>
</tr>
</tbody>
</table>

Those statuses may be classified in:

- Read communication statuses: i.e., those that are related to arrival of data, namely DATA_ON_READERS and DATA_AVAILABLE.
- Plain communication statuses: i.e., all the others.

Read communication statuses are treated slightly differently than the others for they don’t change independently. In other words, at least two changes will appear at the same time (DATA_ON_READERS + DATA_AVAILABLE) and even several of the last kind may be part of the set. This ‘grouping’ has to be communicated to the application. How this is done is discussed in each of the two following sub clauses.
For each plain communication status, there is a corresponding structure to hold the status value. These values contain the information related to the change of status, as well as information related to the statuses themselves (e.g., contains cumulative counts). They are used with the two different mechanisms explained in the following sub clauses.

**Figure 2.13 - Status Values**

The interpretation of the attributes for each status value is provided in the following table.
<table>
<thead>
<tr>
<th><strong>SampleLostStatus</strong></th>
<th>Attribute meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>total_count</strong></td>
<td>Total cumulative count of all samples lost across of instances of data published under the <em>Topic</em>.</td>
</tr>
<tr>
<td><strong>total_count_change</strong></td>
<td>The incremental number of samples lost since the last time the listener was called or the status was read.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>SampleRejectedStatus</strong></th>
<th>Attribute meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>total_count</strong></td>
<td>Total cumulative count of samples rejected by the DataReader.</td>
</tr>
<tr>
<td><strong>total_count_change</strong></td>
<td>The incremental number of samples rejected since the last time the listener was called or the status was read.</td>
</tr>
<tr>
<td><strong>last_reason</strong></td>
<td>Reason for rejecting the last sample rejected. If no samples have been rejected, the reason is the special value NOT_REJECTED.</td>
</tr>
<tr>
<td><strong>last_instance_handle</strong></td>
<td>Handle to the instance being updated by the last sample that was rejected.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>InconsistentTopicStatus</strong></th>
<th>Attribute meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>total_count</strong></td>
<td>Total cumulative count of the Topics discovered whose name matches the Topic to which this status is attached and whose type is inconsistent with the Topic.</td>
</tr>
<tr>
<td><strong>total_count_change</strong></td>
<td>The incremental number of inconsistent topics discovered since the last time the listener was called or the status was read.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>LivelinessChangedStatus</strong></th>
<th>Attribute meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>alive_count</strong></td>
<td>The total number of currently active DataWriters that write the Topic read by the DataReader. This count increases when a newly matched DataWriter asserts its liveliness for the first time or when a DataWriter previously considered to be not alive reasserts its liveliness. The count decreases when a DataWriter considered alive fails to assert its liveliness and becomes not alive, whether because it was deleted normally or for some other reason.</td>
</tr>
<tr>
<td><strong>not_alive_count</strong></td>
<td>The total count of currently DataWriters that write the Topic read by the DataReader that are no longer asserting their liveliness. This count increases when a DataWriter considered alive fails to assert its liveliness and becomes not alive for some reason other than the normal deletion of that DataWriter. It decreases when a previously not alive DataWriter either reasserts its liveliness or is deleted normally.</td>
</tr>
<tr>
<td><strong>alive_count_change</strong></td>
<td>The change in the alive_count since the last time the listener was called or the status was read.</td>
</tr>
<tr>
<td><strong>not_alive_count_change</strong></td>
<td>The change in the not_alive_count since the last time the listener was called or the status was read.</td>
</tr>
<tr>
<td><strong>last_publication_handle</strong></td>
<td>Handle to the last DataWriter whose change in liveliness caused this status to change.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>RequestedDeadlineMissedStatus</strong></th>
<th>Attribute meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>total_count</strong></td>
<td>Total cumulative number of missed deadlines detected for any instance read by the DataReader. Missed deadlines accumulate; that is, each deadline period the <code>total_count</code> will be incremented by one for each instance for which data was not received.</td>
</tr>
<tr>
<td><strong>total_count_change</strong></td>
<td>The incremental number of deadlines detected since the last time the listener was called or the status was read.</td>
</tr>
<tr>
<td><strong>last_instance_handle</strong></td>
<td>Handle to the last instance in the DataReader for which a deadline was detected.</td>
</tr>
</tbody>
</table>

**RequestedIncompatibleQosStatus**
- **total_count** Total cumulative number of times the concerned DataReader discovered a DataWriter for the same Topic with an offered QoS that was incompatible with that requested by the DataReader.
- **total_count_change** The change in `total_count` since the last time the listener was called or the status was read.
- **last_policy_id** The QosPolicyId_t of one of the policies that was found to be incompatible the last time an incompatibility was detected.
- **policies** A list containing for each policy the total number of times that the concerned DataReader discovered a DataWriter for the same Topic with an offered QoS that is incompatible with that requested by the DataReader.

**LivelinessLostStatus**
- **total_count** Total cumulative number of times that a previously-alive DataWriter became not alive due to a failure to actively signal its liveliness within its offered liveliness period. This count does not change when an already not alive DataWriter simply remains not alive for another liveliness period.
- **total_count_change** The change in `total_count` since the last time the listener was called or the status was read.

**OfferedDeadlineMissedStatus**
- **total_count** Total cumulative number of offered deadline periods elapsed during which a DataWriter failed to provide data. Missed deadlines accumulate; that is, each deadline period the `total_count` will be incremented by one.
- **total_count_change** The change in `total_count` since the last time the listener was called or the status was read.
- **last_instance_handle** Handle to the last instance in the DataWriter for which an offered deadline was missed.

**OfferedIncompatibleQosStatus**
- **total_count** Total cumulative number of times the concerned DataWriter discovered a DataReader for the same Topic with a requested QoS that is incompatible with that offered by the DataWriter.
- **total_count_change** The change in `total_count` since the last time the listener was called or the status was read.
Associated with each one of an Entity’s communication status is a logical `StatusChangedFlag`. This flag indicates whether that particular communication status has changed since the last time the status was ‘read’ by the application. The way the status changes is slightly different for the Plain Communication Status and the Read Communication status.
2.2.4.2.1 Changes in Plain Communication Status

For the plain communication status, the StatusChangedFlag flag is initially set to FALSE. It becomes TRUE whenever the plain communication status changes and it is reset to FALSE each time the application accesses the plain communication status via the proper get_<plain communication status> operation on the Entity.

The communication status is also reset to FALSE whenever the associated listener operation is called as the listener implicitly accesses the status which is passed as a parameter to the operation. The fact that the status is reset prior to calling the listener means that if the application calls the get_<plain communication status> from inside the listener it will see the status already reset.

An exception to this rule is when the associated listener is the ‘nil’ listener. As described in 2.2.4.3.1 the ‘nil’ listener is treaded as a NOOP and the act of calling the ‘nil’ listener does not reset the communication status.

For example, the value of the StatusChangedFlag associated with the REQUESTED_DEADLINE_MISSED status will become TRUE each time new deadline occurs (which increases the total_count field within Entity).
RequestedDeadlineMissedStatus). The value changes to FALSE when the application accesses the status via the corresponding get_requested_deadline_missed_status method on the proper Entity.

2.2.4.2.2 Changes in Read Communication Statuses

For the read communication status, the StatusChangedFlag flag is initially set to FALSE.

The StatusChangedFlag becomes TRUE when either a data-sample arrives or else the ViewState, SampleState, or InstanceState of any existing sample changes for any reason other than a call to DataReader::read, DataReader::take or their variants. Specifically any of the following events will cause the StatusChangedFlag to become TRUE:

- The arrival of new data.
- A change in the InstanceState of a contained instance. This can be caused by either:
  - The arrival of the notification that an instance has been disposed by:
    - the DataWriter that owns it if OWNERSHIP QoS kind=EXLUSIVE, or by
    - any DataWriter if OWNERSHIP QoS kind=SHARED.
  - The loss of liveliness of the DataWriter of an instance for which there is no other DataWriter.
  - The arrival of the notification that an instance has been unregistered by the only DataWriter that is known to be writing the instance.

Depending on the kind of StatusChangedFlag, the flag transitions to FALSE again as follows:

- The DATA_AVAILABLE StatusChangedFlag becomes FALSE when either the corresponding listener operation (on_data_available) is called or the read or take operation (or their variants) is called on the associated DataReader.
- The DATA_ON_READERS StatusChangedFlag becomes FALSE when any of the following events occurs:
  - The on_data_available listener operation is called on any DataReader belonging to the Subscriber.
  - The read or take operation (or their variants) is called on any DataReader belonging to the Subscriber.
2.2.4.3 Access through Listeners

Listeners provide a mechanism for the middleware to asynchronously alert the application of the occurrence of relevant status changes.

All Entity support a listener, which type of which is specialized to the specific type of the related Entity (e.g., DataReaderListener for the DataReader). Listeners are interfaces that the application must implement. Each dedicated listener presents a list of operations that correspond to the relevant communication status changes (i.e., that the application may react to).
All listeners are listed on Figure 2.17, associated with the DCPS constructs that participate in this mechanism (note that only the related operations are displayed).

![Figure 2.17 - Supported DCPS Listeners](image)

Listeners are stateless. It is thus possible to share the same `DataReaderListener` instance among all the `DataReader` objects (assuming that they will react similarly on similar status changes). Consequently, the provided parameter contains a reference to the actual concerned `Entity`.

### 2.2.4.3.1 Listener Access to Plain Communication Status

The general mapping between the plain communication statuses as explained in 2.2.4.1 and the listeners’ operations is as follows:

- For each communication status, there is a corresponding operation whose name is `on_<communication_status>`, which takes a parameter of type `<communication_status>` as listed in 2.2.4.1, Communication Status.

- `on_<communication_status>` is available on the relevant `Entity` as well as those that embed it, as expressed in the following figure:
• When the application attaches a listener on an entity, it must set a mask that indicates to the middleware which operations are enabled within this listener (see operation Entity::set_listener).

• When a plain communication status changes\textsuperscript{29}, the middleware triggers the most ‘specific’ relevant listener operation that is enabled\textsuperscript{30}. In case the most specific relevant listener operation corresponds to an application-installed ‘nil’ listener the operation will be considered handled by a NO-OP operation.

This behavior allows the application to set a default behavior (e.g., in the listener associated with the DomainParticipant) and setting dedicated behaviors only where needed.

\subsection{2.2.4.3.2 Listener access to Read Communication Status}

The two statuses related to data arrival are treated slightly differently. Since they constitute the real purpose of the Data Distribution Service, there is not really a need to provide a default mechanism as for the plain communication statuses, and more importantly, several of them may need to be treated as a whole as explained in 2.2.4.1, Communication Status.

The rule is as follows. Each time the read communication status changes\textsuperscript{31}:

• first, the middleware tries to trigger the SubscriberListener operation on_data_on_readers with a parameter of the related Subscriber;

• if this does not succeed (no listener or operation non-enabled), it tries to trigger on_data_available on all the related DataReaderListener objects, with as parameter the related DataReader.

\textsuperscript{29}To be more precise, when the corresponding StatusChangedFlag described in “2.2.4.2.1, Changes in Plain Communication Status” becomes TRUE.

\textsuperscript{30}For example, in case of ON_OFFERED_DEADLINE_MISSED for a given DataWriter: the DataWriter’s listener operation on_offered_deadline_missed, or by default (i.e., if there was no listener attached to that DataWriter, or if the operation was not enabled), the Publisher’s listener or else (no listener attached to the Publisher or operation not enabled) the DomainParticipant’s listener.

\textsuperscript{31}To be more precise, when the corresponding StatusChangedFlag described in “2.2.4.2.2, Changes in Read Communication Status” becomes TRUE.
The rationale is that either the application is interested in relations among data arrivals and it must use the first option (and then get the corresponding \texttt{DataReader} objects by calling \texttt{get_datareaders} on the related \texttt{Subscriber} and then get the data by calling \texttt{read/take} on the returned \texttt{DataReader} objects\textsuperscript{32}, or it wants to treat each \texttt{DataReader} fully independently and it may choose the second option (and then get the data by calling \texttt{read/take} on the related \texttt{DataReader}).

Note that if \texttt{on_data_on_readers} is called, then the middleware will not try to call \texttt{on_data_available}, however, the application can force a call to the \texttt{DataReader} objects that have data by means of the \texttt{notify_datareaders} operation.

There is no implied “event queuing” in the invocation of the listeners in the sense that, if several changes of status of the same kind occur in sequence, it is not necessary that the DCPS implementation delivers one listener callback per “unit” change. For example, it may occur that the DCPS implementation discovers that the liveliness of a \texttt{DataReader} has changed in that several matching \texttt{DataWriter} entities have appeared; in that case the DCPS implementation may choose to invoke the \texttt{on_liveliness_changed} operation on the \texttt{DataReaderListener} just once, as long as the \texttt{LivelinessChangedStatus} provided to the listener corresponds to the most current one.

2.2.4.4 Conditions and Wait-sets

As previously mentioned, conditions (in conjunction with wait-sets) provide an alternative mechanism to allow the middleware to communicate communication status changes (including arrival of data) to the application.

Figure 2.19 - Wait-sets and Conditions shows all the DCPS constructs that are involved in that mechanism (note that only the related operations are displayed).

\textsuperscript{32}As detailed in 2.2.2.5, Subscription Module.
Figure 2.19 - Wait-sets and Conditions

This mechanism is wait-based. Its general use pattern is as follows:

- The application indicates which relevant information it wants to get, by creating `Condition` objects (StatusCondition, ReadCondition or QueryCondition) and attaching them to a `WaitSet`.

- It then waits on that `WaitSet` until the `trigger_value` of one or several `Condition` objects become TRUE.
• It then uses the result of the `wait` (i.e., the list of `Condition` objects with `trigger_value`==TRUE) to actually get the information by calling:
  - `get_status_changes` and then `get_<communication_status>` on the relevant `Entity`. If the condition is a `StatusCondition` and the status changes, refer to plain communication status.
  - `get_status_changes` and then `get_datareaders` on the relevant `Subscriber`. If the condition is a `StatusCondition` and the status changes, refers to DATA_ON_READERS.  
  - `get_status_changes` and then `read/take` on the relevant `DataReader`. If the condition is a `StatusCondition` and the status changes, refers to DATA_AVAILABLE.
  - Directly `read_w_condition/take_w_condition` on the `DataReader` with the `Condition` as a parameter if it is a `ReadCondition` or a `QueryCondition`.

Usually the first step is done in an initialization phase, while the others are put in the application main loop.

As there is no extra information passed from the middleware to the application when a wait returns (only the list of triggered `Condition` objects), `Condition` objects are meant to embed all that is needed to react properly when enabled. In particular, `Entity`-related conditions are related to exactly one `Entity` and cannot be shared.

The blocking behavior of the `WaitSet` is illustrated in Figure 2.20. The result of a `wait` operation depends on the state of the `WaitSet`, which in turn depends on whether at least one attached `Condition` has a `trigger_value` of TRUE. If the `wait` operation is called on a `WaitSet` with state BLOCKED, it will block the calling thread. If `wait` is called on a `WaitSet` with state UNBLOKCED, it will return immediately. In addition, when the `WaitSet` transitions from BLOCKED to UNBLOKCED it wakes up any threads that had called `wait` on it.

Similar to the invocation of listeners, there is no implied “event queuing” in the awakening of a `WaitSet` in the sense that, if several Conditions attached to the `WaitSet` have their `trigger_value` transition to TRUE in sequence the DCPS implementation needs to only unblock the `WaitSet` once.

![Blocking behavior of WaitSet](image)

**Figure 2.20 - Blocking behavior of WaitSet**

A key aspect of the `Condition/WaitSet` mechanism is the setting of the `trigger_value` of each `Condition`.

33. See 2.2.2.1 for general definition of conditions; see 2.2.2.5 for `ReadCondition` and `QueryCondition`.
34. And then read/take on the returned `DataReader` objects.
35. For instance, `StatusCondition`, `ReadCondition` and `QueryCondition`. See 2.2.2.1 on the use of basic `Condition`. 
2.2.4.4.1 Trigger State of the StatusCondition

The trigger_value of a StatusCondition is the Boolean OR of the ChangedStatusFlag of all the communication statuses to which it is sensitive. That is, trigger_value==FALSE only if all the values of the ChangedStatusFlags are FALSE.

The sensitivity of the StatusCondition to a particular communication status is controlled by the list of enabled_statuses set on the condition by means of the set_enabled_statuses operation.

2.2.4.5 Trigger State of the ReadCondition

Similar to the StatusCondition, a ReadCondition also has a trigger_value that determines whether the attached WaitSet is BLOCKED or UNBLOCKED. However, unlike the StatusCondition, the trigger_value of the ReadCondition is tied to the presence of at least a sample managed by the Service with SampleState, ViewState, and InstanceState matching those of the ReadCondition. Furthermore, for the QueryCondition to have a trigger_value==TRUE, the data associated with the sample must be such that the query_expression evaluates to TRUE.

The fact that the trigger_value of a ReadCondition is dependent on the presence of samples on the associated DataReader implies that a single take operation can potentially change the trigger_value of several ReadCondition or QueryCondition conditions. For example, if all samples are taken, any ReadCondition and QueryCondition conditions associated with the DataReader that had their trigger_value==TRUE before will see the trigger_value change to FALSE. Note that this does not guarantee that WaitSet objects that were separately attached to those conditions will not be woken up. Once we have trigger_value==TRUE on a condition it may wake up the attached WaitSet, the condition transitioning to trigger_value==FALSE does not necessarily ‘unwakeup’ the WaitSet as ‘unwakening’ may not be possible in general. The consequence is that an application blocked on a WaitSet may return from the wait with a list of conditions some of which are no longer “active.” This is unavoidable if multiple threads are concurrently waiting on separate WaitSet objects and taking data associated with the same DataReader entity.

To elaborate further, consider the following example: A ReadCondition that has a sample_state_mask = {NOT_READ} will have trigger_value of TRUE whenever a new sample arrives and will transition to FALSE as soon as all the newly-arrived samples are either read (so their status changes to READ) or taken (so they are no longer managed by the Service). However if the same ReadCondition had a sample_state_mask = {READ, NOT_READ}, then the trigger_value would only become FALSE once all the newly-arrived samples are taken (it is not sufficient to read them as that would only change the SampleState to READ which overlaps the mask on the ReadCondition.

2.2.4.5.1 Trigger State of the GuardCondition

The trigger_value of a GuardCondition is completely controlled by the application via operation set_trigger_value.

2.2.4.6 Combination

Those two mechanisms may be combined in the application (e.g., using wait-sets and conditions to access the data and listeners to be warned asynchronously of erroneous communication statuses).

It is likely that the application will choose one or the other mechanism for each particular communication status (not both). However, if both mechanisms are enabled, then the listener mechanism is used first and then the WaitSet objects are signalled.
2.2.5 Built-in Topics

As part of its operation, the middleware must discover and possibly keep track of the presence of remote entities such as a new participant in the domain. This information may also be important to the application, which may want to react to this discovery, or else access it on demand.

To make this information accessible to the application, the DCPS specification introduces a set of built-in topics and corresponding DataReader objects that can then be used by the application. The information is then accessed as if it was normal application data. This approach avoids introducing a new API to access this information and allows the application to become aware of any changes in those values by means of any of the mechanisms presented in 2.2.4, Listeners, Conditions, and Wait-sets.

The built-in data-readers all belong to a built-in Subscriber. This subscriber can be retrieved by using the method get_builtin_subscriber provided by the DomainParticipant. The built-in DataReader objects can be retrieved by using the operation lookup_datareader, with the Subscriber and the topic name as parameters.

The QoS of the built-in Subscriber and DataReader objects is given by the following table:

| USER_DATA | <unspecified> |
| TOPIC_DATA | <unspecified> |
| GROUP_DATA | <unspecified> |
| DURABILITY | TRANSIENT_LOCAL |
| DURABILITY_SERVICE | Does not apply as DURABILITY is TRANSIENT_LOCAL |
| PRESENTATION | access_scope = TOPIC  
coherent_access = FALSE  
ordered_access = FALSE |
| DEADLINE | Period = infinite |
| LATENCY_BUDGET | duration = <unspecified> |
| OWNERSHIP | SHARED |
| LIVELINESS | kind = AUTOMATIC  
lease_duration = <unspecified> |
| TIME_BASED_FILTER | minimum_separation = 0 |
| PARTITION | <unspecified> |
| RELIABILITY | kind = RELIABLE  
max_blocking_time = 100 milliseconds |
| DESTINATION_ORDER | BY_RECEPTION_TIMESTAMP |
| HISTORY | kind = KEEP_LAST  
depth = 1 |
| RESOURCE_LIMITS | All LENGTH_UNLIMITED. |
| READER_DATA_LIFECYCLE | autopurge_nowriter_samples_delay = infinite  
apopurge_disposed_samples_delay = infinite |
| ENTITY_FACTORY | autoenable_created_entities = TRUE |
Built-in entities have default listener settings as well. The built-in *Subscriber* and all of its built-in *Topics* have nil listeners with all statuses appearing in their listener masks. The built-in *DataReaders* have nil listeners with no statuses in their masks.

The information that is accessible about the remote entities by means of the built-in topics includes all the QoS policies that apply to the corresponding remote Entity. This QoS policies appear as normal ‘data’ fields inside the data read by means of the built-in Topic. Additional information is provided to identify the Entity and facilitate the application logic.

A built-in *DataReader* obtained from a given *Participant* will not provide data pertaining to *Entities* created from that same *Participant* under the assumption that such entities are already known to the application that created them.

The table below lists the built-in topics, their names, and the additional information--beyond the QoS policies that apply to the remote entity--that appears in the data associated with the built-in topic.

### 2.2.6 Interaction Model

Two interaction models are shown here to illustrate the behavior of the DCPS. The first one concerns publication, the second one subscription.

It should be noted that these models are not intended to explain how the Service is implemented. In particular, what happens on the right side of the picture (e.g., which components actually send the notifications) should be understood as how it may work rather than how it actually does work (as written inside quotes on the diagrams).

Root OfTheWorld:

Figure 2.21 - DCPS Interaction Model (Publication)
The first part of Figure 2.21 shows the Publisher’s creation. The second part shows that topics must be created before they are referred to by a DataWriter. It should be noted that the topic creation can be requested by a different actor than the one that will use it afterward (in that case, it has to be searched by TopicFactory::get_topic).

The third part of Figure 2.21 shows the DataWriter’s creation. Then, a write and a dispose operation are issued on the DataWriter, which immediately informs the Publisher. Since the application has not invoked the suspend_publications operation on the Publisher, the corresponding notifications are propagated according to the current Publisher’s policy regarding sending.\textsuperscript{36}

The last part of Figure 2.21 shows the same kind of interactions embedded into a pair of suspend_publications/resume_publications. It is important to take into account that the corresponding notifications are now delayed until the last resume_publications. It should also be noted that even if the diagram shows only one DataWriter, several of them could be bracketed within a suspend/resume pair.

2.2.6.2 Subscription View

On the subscription side, two diagrams are given. The first one (see Figure 2.22) shows how it works when listeners are used, while the second (see Figure 2.23) shows the use of conditions and wait-sets.

2.2.6.2.1 Notification via Listeners

The first part of Figure 2.22 shows the Subscriber’s and the DataReader’s creation by means of the DomainParticipant.

The second part shows the use of a SubscriberListener: It must first be created and attached to the Subscriber (set_listener). Then when data arrives, it is made available to each related DataReader. Then the SubscriberListener is triggered (on_data_on_readers). The application must then get the list of affected DataReader objects (get_datareaders); then it can read/take the data directly on these objects.

Alternatively, the third part of the diagram shows the use of DataReaderListener objects that are first created and attached to the readers. When data is made available on a DataReader, the related listener is triggered and data can be read (read/take). It should be noted that, in this case, no link between readers can be retrieved.

NOTE: When the two kinds of listeners are set, the SubscriberListener supersedes the DataReaderListener ones.

\textsuperscript{36}Usually, this means that the notifications are sent immediately.
Figure 2.22 - DCPS Interaction Model (Subscription with Listeners)
2.2.6.2.2 Notifications via Conditions and Wait-Sets

The first part of Figure 2.23 shows the Subscriber’s and the DataReader’s creation by means of the DomainParticipant.

The second part shows the creation of a WaitSet and a ReadCondition, the attachment of the latter to the former, and the call to the WaitSet::wait operation. Note that it is likely that several conditions (ReadCondition, but also StatusCondition) will be created and attached to the same WaitSet.

The third part of the diagram shows the information flow when data is received. Note that the wait returns the list of all the enabled conditions, in an arrival cycle: in case several DataReader objects receive available data, several conditions will be set enabled at the same time and the application will perform several read accordingly.

NOTE: With conditions and wait-sets, read operations are executed naturally in the user context.
Figure 2.23 - DCPS Interaction Model (Subscriptions with Conditions)
2.3 OMG IDL Platform Specific Model (PSM)

2.3.1 Introduction

The OMG IDL PSM is provided by means of the IDL that defines the interface an application can use to interact with the Service.

2.3.2 PIM to PSM Mapping Rules

A key concern in the development of the interface is performance. This is a consequence of the application space targeted by the Data Distribution Service (DDS).

‘Out’ parameters in the PIM are conventionally mapped to ‘inout’ parameters in the PSM in order to minimize the memory allocation performed by the Service and allow for more efficient implementations. The intended meaning is that the caller of such an operation should provide an object to serve as a “container” and that the operation will then “fill in” the state of that object appropriately.

The PIM to PSM mapping maps the UML interfaces and classes interfaces into IDL interfaces. Plain data types are mapped into structures.

IDL interfaces do not support overloading. The cases where a base class or interface has an abstract operation that must be redefined by a specialized class or interface has been mapped into a base IDL interface where the abstract operation appears inside comments. This serves simply as a reminder of the fact that all specializations must implement the operation.

Enumerations have been mapped into either IDL ‘enum’ or hand-picked IDL ‘long’ values that correspond to increasing powers of 2 (that is 0x01, 0x02, 0x04, etc.). The latter choice has been made when it was required to refer to multiple values as part of a function parameter. This allowed the use of a ‘long’ as a mask to indicate a set of enumerated values. This selection affected only the PIM ‘status kind’ values, namely: StatusKind, SampleStateKind, ViewStateKind, and InstanceStateKind. The name of the mask type is formed by replacing the word ‘Kind’ with the word ‘Mask’ as in StatusMask, SampleStateMask, etc.

Collection parameters have been mapped into IDL sequences. The only exception applies to the case where the collection elements are hand-picked IDL ‘long.’ In this case the collection is mapped into an IDL ‘long’ interpreted as a mask.

Each QosPolicy has been mapped as an IDL struct. The collection of policies suitable for each Entity has been modeled as another IDL struct that contains attributes corresponding to the policies that apply to this Entity. This approach has several advantages. First, it provides compile-time checking of the suitability of setting a specific QosPolicy on a particular Entity. A second advantage is that it does not require the use of the type “any” which increases code size and is not natural to use in “C.” Other approaches were less attractive. IDL interfaces are not suitable because a collection of QosPolicy appears as an argument to several operations and needs to be passed “by value.” IDL ‘valuetype’ was considered but rejected because it is not universally supported and also forces each attribute to be accessed via an operation.

Error-return values have been mapped to plain return codes of the corresponding functions. The reason is that DCPS targets “C” as one of the key deployment languages and return codes are more natural to use in “C.”

The DataSample class that associates the SampleInfo and Data collections returned from the data-accessing operations (read and take) have not been explicitly mapped into IDL. The collections themselves have been mapped into sequences. The correspondence between each Data and SampleInfo is represented by the use of the same index to access the corresponding elements on each of the collections. It is anticipated that additional data-accessing API’s may be provided on each target language to make this operation as natural and efficient is it can be. The reason is that accessing data is the main purpose of the
Data-Distribution service, and, the IDL mapping provides a programming-language neutral representation that cannot take advantage of the strengths of each particular language.

The classes that do not have factory operations, namely *WaitSet* and *GuardCondition* are mapped to IDL interfaces. The intent is that they will be implemented as native classes on each of the implementation languages and they will be constructed using the “new” operator natural for that language. Furthermore, the implementation language mapping should offer at least a constructor that takes no arguments such that applications can be portable across different vendor implementations of this mapping.

The language implementations of the DomainParticipantFactory interface should have the static operation *get_instance* described in 2.2.2.2.2. This operation does not appear in the IDL interface *DomainParticipantFactory* as static operations cannot be expressed in IDL.

The two types used to represent time: *Duration_t* and *Time_t* are mapped into structures that contain fields for the second and the nanosecond parts. These types are further constrained to always use a ‘normalized’ representation for the time, that is, the *nanosec* field must verify $0 \leq \text{nanosec} < 1000000000$.

The IDL PSM introduces a number of types that are intended to be defined in a native way. As these are opaque types, the actual definition of the type does not affect portability and is implementation dependent. For completeness the names of the types appear as typedefs in the IDL and a #define with the suffix “_TYPE_NATIVE” is used as a place-holder for the actual type. The type used in the IDL by this means is not normative and an implementation is allowed to use any other type, including non-scalar (i.e., structured types).

Annex A - Compliance Points

This specification includes the following compliance profiles.

- **Minimum profile**: This profile contains just the mandatory features of DCPS. None of the optional features are included.

- **Content-subscription profile**: This profile adds the optional classes: `ContentFilteredTopic`, `QueryCondition`, `MultiTopic`. This profile enables subscriptions by content. See 2.2.2.3, Topic-Definition Module.

- **Persistence profile**: This profile adds the optional QoS policy `DURABILITY_SERVICE` as well as the optional settings ‘TRANSIENT’ and ‘PERSISTENT’ of the DURABILITY QoS policy `kind`. This profile enables saving data into either TRANSIENT memory, or permanent storage so that it can survive the lifecycle of the `DataWriter` and system outages. See 2.2.3.4, DURABILITY.

- **Ownership profile**: This profile adds two things First the optional setting ‘EXCLUSIVE’ of the OWNERSHIP `kind`. Second support for the optional OWNERSHIP_STRENGTH policy. Third the ability to set a `depth` > 1 for the HISTORY QoS policy.

- **Group access profile**: This profile includes support for the PRESENTATION `access_scope` setting of ‘GROUP’ (see 2.2.3.6, PRESENTATION).
Annex B - Syntax for Queries and Filters

B.1 Introduction

A subset of SQL syntax is used in several parts of the specification:

- The *filter_expression* in the *ContentFilteredTopic* (see 2.2.2.3.3, ContentFilteredTopic Class).
- The *topic_expression* in the *MultiTopic* (see 2.2.2.3.4, MultiTopic Class [optional]).
- The *query_expression* in the *QueryReadCondition* (see 2.2.2.5.9, QueryCondition Class).

Those expressions may use a subset of SQL, extended with the possibility to use program variables in the SQL expression. The allowed SQL expressions are defined with the BNF-grammar below.

The following notational conventions are made:

- *NonTerminals* are typeset in italics.
- *Terminals* are quoted and typeset in a fixed width font.
- *TOKENS* are typeset in small caps.
- The notation *(element // ',')* represents a non-empty comma-separated list of *elements*.

B.2 SQL grammar in BNF

```
Expression ::= FilterExpression
         | TopicExpression
         | QueryExpression.

FilterExpression ::= Condition.

TopicExpression ::= SelectFrom {Where} ';'.

QueryExpression ::= {Condition}{'ORDER BY' (FIELDNAME // '','')}
                   .

SelectFrom ::= 'SELECT' Aggregation 'FROM' Selection.

Aggregation ::= '*'
              | (SubjectFieldSpec // '','')
              .

SubjectFieldSpec ::= FIELDNAME
                 | FIELDNAME 'AS' FIELDNAME
```
FIELDNAME FIELDNAME.

Selection ::= TOPICNAME
| TOPICNAME NaturalJoin JoinItem.

JoinItem ::= TOPICNAME
| TOPICNAME NaturalJoin JoinItem
| '(' TOPICNAME NaturalJoin JoinItem ')'.

NaturalJoin ::= 'INNER NATURAL JOIN'
| 'NATURAL JOIN'
| 'NATURAL INNER JOIN'.

Where ::= 'WHERE' Condition.

Condition ::= Predicate
| Condition 'AND' Condition
| Condition 'OR' Condition
| 'NOT' Condition
| '(' Condition ')'.

Predicate ::= ComparisonPredicate
| BetweenPredicate.

ComparisonPredicate ::= FIELDNAME RelOp Parameter
| Parameter RelOp FIELDNAME
| FIELDNAME RelOp FIELDNAME.

BetweenPredicate ::= FIELDNAME 'BETWEEN' Range
| FIELDNAME 'NOT BETWEEN' Range.

RelOp ::= '=' | '>' | '>=' | '<' | '<=' | '<>' | like.

Range ::= Parameter 'AND' Parameter.
Parameter ::= INTEGERVALUE
   | CHARVALUE
   | FLOATVALUE
   | STRING
   | ENUMERATEDVALUE
   | PARAMETER

NOTE: INNER NATURAL JOIN, NATURAL JOIN, and NATURAL INNER JOIN are all aliases, in the sense that they have the same semantics. They are all supported because they all are part of the SQL standard.

Token expression

The syntax and meaning of the tokens used in the SQL grammar is described as follows:

- FIELDNAME - A fieldname is a reference to a field in the data-structure. The dot ‘.’ is used to navigate through nested structures. The number of dots that may be used in a FIELD-NAME is unlimited. The FIELDNAME can refer to fields at any depth in the data structure. The names of the field are those specified in the IDL definition of the corresponding structure, which may or may not match the field-names that appear on the language-specific (e.g., C/ C++, Java) mapping of the structure.

- TOPICNAME - A topic name is an identifier for a topic, and is defined as any series of characters ‘a’, ..., ‘z’, ‘A’, ..., ‘Z’, ‘0’, ..., ‘9’, ‘-’ but may not start with a digit.

- INTEGERVALUE - Any series of digits, optionally preceded by a plus or minus sign, representing a decimal integer value within the range of the system. A hexadecimal number is preceded by 0x and must be a valid hexadecimal expression.

- CHARVALUE - A single character enclosed between single quotes.

- FLOATVALUE - Any series of digits, optionally preceded by a plus or minus sign and optionally including a floating point (‘.’). A power-of-ten expression may be postfixed, which has the syntax en, where n is a number, optionally preceded by a plus or minus sign.

- STRING - Any series of characters encapsulated in single quotes, except a new-line character or a right quote. A string starts with a left or right quote, but ends with a right quote.

- ENUMERATEDVALUE - An enumerated value is a reference to a value declared within an enumeration. Enumerated values consist of the name of the enumeration label enclosed in single quotes. The name used for the enumeration label must correspond to the label names specified in the IDL definition of the enumeration.

- PARAMETER - A parameter is of the form %n, where n represents a natural number (zero included) smaller than 100. It refers to the n + 1 th argument in the given context.

Examples

Assuming Topic “Location” has as an associated type a structure with fields “flight_name, x, y, z”, and Topic “FlightPlan” has as fields “flight_id, source, destination”. The following are examples of using these expressions.
Example of a *topic_expression*:

- “SELECT flight_name, x, y, z AS height FROM ‘Location’ NATURAL JOIN ‘FlightPlan’ WHERE height < 1000 AND x <23”

Example of a *query_expression* or a *filter_expression*:

- “height < 1000 AND x <23”
