dtc/2015-02-11 (Annex C Business Usage Guidelines)

OMG's Issue Reporting Procedure

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page http://www.omg.org, under Documents, Report a Bug/Issue (http://www.omg.org/report_issue.htm).

Preface

About the Object Management Group

OMG

Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer industry standards consortium that produces and maintains computer industry specifications for interoperable, portable and reusable enterprise applications in distributed, heterogeneous environments. Membership includes Information Technology vendors, end users, government agencies and academia.

OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle approach to enterprise integration that covers multiple operating systems, programming languages, middleware and networking infrastructures, and software development environments. OMG's specifications include: UML® (Unified Modeling LanguageTM); CORBA® (Common Object Request Broker Architecture); CWMTM (Common Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

More information on the OMG is available at http://www.omg.org/.

OMG Specifications

As noted, OMG specifications address middleware, modeling and vertical domain frameworks. All OMG Formal Specifications are available from this URL:

http://www.omg.org/spec

Specifications are organized by the following categories:

Business Modeling Specifications

Middleware Specifications

- CORBA/IIOP
- Data Distribution Services
- Specialized CORBA

IDL/Language Mapping Specifications

Modeling and Metadata Specifications

- UML, MOF, CWM, XMI
- UML Profile

Modernization Specifications

OMG Domain Specifications

Platform Independent Model (PIM), Platform Specific Model (PSM), Interface Specifications

- CORBAServices
- CORBAFacilities

OMG Domain Specifications

CORBA Embedded Intelligence Specifications

CORBA Security Specifications

Signal and Image Processing Specifications

All of OMG's formal specifications may be downloaded without charge from our website. (Products implementing OMG specifications are available from individual suppliers.) Copies of specifications, available in PostScript and PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management Group, Inc. at:

OMG Headquarters 109 Highland Avenue Needham, MA 02494 USA

Tel: +1-781-444-0404 Fax: +1-781-444-0320 Email: pubs@omg.org

Certain OMG specifications are also available as ISO standards. Please consult http://www.iso.org

Issues

The reader is encouraged to report any technical or editing issues/problems with this specification to http://www.omg.org/report_issue.htm.

1 Scope

Many SBVR rules involve common, generic, cross-domain concepts such as date and time. Characteristics of these concepts are frequent usage in everyday and business activities and wide usage across all business domains such as finance and manufacturing. These concepts exclude specialized needs such as sidereal time and real-time processing requirements. This document uses the term "foundation vocabularies" due to the foundational nature of these vocabularies for all these potential SBVR users.

SBVR tool vendors and users need standard vocabularies for such concepts to improve interoperability among vendors and to ensure that they share the same concepts in the same way. Vendors also need an agreed format for exchange of date and time literals when used in rules. The SBVR community in general needs such vocabularies as a foundation to avoid the startup cost of defining vocabularies for basic concepts, and as an example for interoperability testing among tools. The OMG wants SBVR to be successful, and sees value in lowering the "cost of entry" for potential SBVR users.

This document addresses two different, but complementary, aspects of time:

- Type 1: Temporal noun concepts (such as time coordinate, duration, calendar, etc.) that model attributes of SBVR noun concepts, and temporal verb concepts (such as time coordinate is in the past, time interval, is before time interval, time interval, includes time interval, etc.) that model relationships between temporal noun concepts. See Clauses 8 through 8.2.
- Type 2: Fact types that relate <u>situation kinds</u> and <u>occurrences</u> (such as a person being married to another person) to temporal concepts (e.g., to a <u>time interval</u>). See normative clause 16, as well as informative clauses 7.9 and 7.11, and informative Annex E.

These two aspects reflect the use/mention distinction well known from analytical philosophy: the first mentions temporal concepts, whereas the second uses temporal concepts in order to anchor situation kinds and occurrences in time.

The OMG's Model Driven Architecture (MDA) anticipates mappings between business-layer or Computation Independent Models (CIM) and implementation-layer Platform Independent (PIM) and Platform Specific (PSM) Models. To encourage such mappings, this document provides date and time models in UML (Unified Markup Language) plus OCL (Object Constraint Language), partially in CLIF (Common Logic Interchange Format), and partially in OWL (Web Ontology Language) modeled in ODM (Ontology Definition Metamodel). The UML, CLIF, and OWL/ODM date and time models are "equivalent" to the SBVR date and time vocabulary while being "true" to the spirit of their respective technologies.

2 Conformance

Conformance to this specification is defined with respect to three types of software:

- Software that manages ontologies complies with this specification if and only if it can import the entire set of
 concepts defined by the Date-Time Vocabulary in at least one of the normative forms specified here.
- Software that implements machine reasoning about time complies with this specification if and only if it interprets the entire set of concepts defined by the Date-Time Vocabulary according to the semantics defined here.
- The compliance of software that interchanges documents containing date and time concepts is specified in Clause 18.

3 Normative References

The following normative documents contain provisions which, through reference in this text, constitute provisions of this specification. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply.

- World Wide Web Consortium (W3C) Recommendation, XML Schema Part 2: Datatypes Second Edition, 28 October 2004

4 Terms and Definitions

Because the Date Time Vocabulary is intended to be a formal vocabulary, the content of this specification is primarily terms, definitions, and examples. Where terms are drawn from other sources, this is noted in the vocabulary entry by a Source caption.

The following terms are taken directly from SBVR and used only with the SBVR meaning, regardless of markup:

- designation
- individual concept
- noun concept
- · ranges over, as 'role ranges over concept'
- verb concept
- verb concept role

Note: The unmarked term 'role' used in this specification means 'verb conceptrole'. The marked up term role refers to a property of something, which SBVR calls a 'situational role'.

The following additional terms are taken from SBVR and have the definitions and other descriptions given therein, when they are marked as SBVR terms. Note: The list below is ordered by the symbol being defined, while SBVR practice is to define verb symbols in the context of the subject term.

- <u>cardinality</u> of <u>set</u> and <u>set</u> has <u>cardinality</u>
- categorization type
- characteristic

- concept
- concept type
- · meaning corresponds to thing
- · definite description
- definition
- element of set and set has element statement expresses proposition
- expression
- extensional definition
- general concept
- <u>set includes thing</u> (= <u>set has element</u>)
- · instance of concept and thing is instance of concept
- intensional definition
- thing₁ is thing₂
- thing is in set (= set includes thing)
- · name of thing and thing has name
- proposition
- representation
- representation has expression
- representation of meaning and meaning has representation
- representation represents meaning (= meaning has representation)
- · res
- · roleset
- · concept₁ specializes concept₂
- statement
- · terminological dictionary
- thing
- · unitary concept
- vocabulary

The following concepts have their usual mathematical meaning but are formally marked as the SBVR terms:

- integer
- nonnegative integer
- number

5 Symbols

This clause specifies the intended meaning of the symbols and other special text of this specification.

5.1 SBVR Vocabulary

Clauses 8 through 17 of this specification introduce the Date-Time Vocabulary as a 'vocabulary,' as defined by the OMG Semantics of Business Vocabulary and Rules specification.

This specification presents the Date-Time Vocabulary in the forms specified in Annex C of SBVR. The intent is that the Date-Time Vocabulary is to be interpreted as specified in SBVR Annex C.2 and C.3, and is to be rendered as an XML document that conforms to the SBVR Metamodel XML Schema that is described in SBVR sub clause 15.2, according to the patterns given in SBVR sub clause 13.6.

The following captions are used as specified by SBVR in formulating vocabularies and terminological entries. In some cases, the corresponding SBVR term is used (with markup, see clause 4) directly in DTV definitions and rules,

- · Concept type
- · General concept
- · Definition
- · Dictionary basis
- · Example
- · Included Vocabulary
- · Language
- Namespace URI
- · Necessity
- · Note
- Possibility
- Source
- · Synonym
- · Synonymous Form
- · Vocabulary

Annex A of this specification identifies the normative attachment that contains the formal representation of the Date-Time Vocabulary as an SBVR Vocabulary in the normative XML document form prescribed by SBVR sub clauses 13.6 and 15.2. The XML document includes all the meanings, definitions, rules, and other representations that are given in this specification in text form.

It is possible to represent most, but not all, of the definitions and rules given in this specification in the formal logical form specified by SBVR Clause 9. That representation may be a normative part of a future version of this specification.

5.2 SBVR Structured English

For definitions of vocabulary terms, and for 'structural rules' (necessities, axioms) that relate to those terms, this document adopts the "SBVR Structured English" syntax and font styles described in Annex C of the SBVR specification [SBVR]:

- <u>Underlined teal</u> indicates noun concepts.
- Italic blue identifies the fact symbols of verb concepts.
- · Orange font indicates keywords.
- Double underlined teal marks individual concepts.
- \bullet Black normal font is regular text.

This specification uses the following symbols for the meanings indicated:

- \leq less than or equal
- $\geq \qquad \text{greater than or equal}$
- < less
- > greater
- = equal
- + addition
- subtraction
- * multiplication
- / division

Ordinary arithmetic is meant when these symbols are used, unstyled, with <u>numbers</u>(e.g., "<u>number1 = number2</u>"). The meaning is explicitly defined in this specification when these symbols are applied (and styled as verb concepts) to other operand types.

Sets are formed using the BNF syntax '{' <element>+ (, <element>)* '}', where <element> gives the members of the set, separated by commas. An empty set is specified by "{}".

This specification uses the SBVR definition of 'thing1 is thing2,' meaning "The thing1 and the thing2 are the same thing." Verb concepts using the fact symbol 'equals,' '=,' or 'is equivalent to' are explicitly defined for usages where the intended meaning is that two values can be distinct things, but are equivalent in terms of their relationship to some other thing. In particular, two quantity values are different things if they involve different units but are equal or equivalent if they quantify the same quantity.

The SBVR specification does not discuss dates and times, and thus does not specify the styling of literal time coordinates (e.g., "January 21 2009"), literal times of day (e.g., "3:00 pm"), and literal duration values (e.g., 3 months 13 days). These values identify themselves, meaning that each such expression identifies exactly one time coordinate, time of day, or duration value – they are what SBVR calls 'individual concepts.' For this reason, literal time coordinates and times of day are styled as individual concepts in this document. For example, January 21 2009 3:00 pm.

In this specification, <u>duration values</u> provide the reference scheme for <u>durations</u> and <u>time coordinates</u> provide the reference scheme for <u>time points</u>. Verb concept roles that apply to <u>durations</u> or <u>time points</u> can be filled by <u>duration values</u> or <u>time coordinates</u>, respectively. For example, "17:00 is 1 hour before the <u>start of the meeting</u>" applies the verb concept "<u>time interval</u> is <u>duration before time interval</u>" using <u>time coordinate</u> "17:00" to fill the "time interval?" role, and <u>duration value</u> "1 hour" to fill the "<u>duration</u>" role. The example assumes that "<u>start of meeting</u>" is a <u>time interval</u> that fills the "<u>time interval</u>" role.

This specification distinguishes between comparing <u>durations</u> or <u>time periods</u>, and quantifying <u>time periods</u>. Comparisons uses verb concepts defined in this document and styled as verb concepts. For example, "if the length of the meeting *is greater than* <u>3 hours</u>..." or "if the date of the meeting *is before* the contract due date ..." Quantifications use keyword style, as in "The party is on <u>each July 4</u>."

Definitions that are drawn from another specification are preceded by "Source" or "Dictionary Basis" captions. "Source" indicates that the definition is adopted exactly from the indicated specification. "Dictionary Basis" identifies definitions that are paraphrased from the specified source.

5.3 UML and OCL

This specification includes a normative UML (Unified Modeling Language) model of the concepts represented in the Date-Time Vocabulary, using the same terms as the SBVR vocabulary to the extent possible. The intent of the UML model is two-fold: (a) to provide a normative PIM (Platform Independent Model) UML representation of the concepts, for use in software models of date and time concepts, and (b) to illustrate the Date-Time Vocabulary with UML diagrams. Annex A of this specification identifies the normative attachment that is the UML model.

The UML model is derived manually from the Date-Time Vocabulary presented in the SBVR form. The UML model is constructed generally following the principles in [SBVR] Clause 13. The names in the UML model are identical to the primary vocabulary terms for the same concepts.

Some SBVR vocabulary items are modeled in the UML model using stereotypes. The stereotypes are formally specified in Annex I.

- · Each SBVR general concept maps to a UML class.
- Each SBVR concept type maps to a UML class with the stereotype «concept type». Where specific concepts that are instances of a concept type are also modeled, the fact that each such a concept is an instance of the concept type is modeled by a UML dependency with the stereotype «instance of».
- Each SBVR categorization type maps to a UML class with the stereotype «categorization type». The relationship between the categorization type and the general concept it categorizes is modeled by a UML dependency with the

stereotype «for general concept».

- Each binary verb concept maps to a UML association. The association is named for the primary verb concept form for the verb concept, discarding all markup. The placeholders (role names) in the verb concept are mapped to the association end names, with subscripts being elevated to plain text.
- Each binary verb concept that uses the SBVR verb symbol has in any of its synonymous forms maps to a UML Property of the class that is the subject of the verb; that is, the association end is owned by the class. In some cases, this means that the association end name (the property name) is taken from the has form, rather than the primary form.
- Regardless of the verb symbol, where the intent of the binary verb concept is that the association represents a property of the class that plays the subject role, the corresponding association end is owned by the class. Similarly, where there is a Synonymous Form that represents a property of the other role (as the subject of that form), the corresponding association end of the same association is owned by the class that plays that role.
- Binary verb concepts that do not clearly imply a property of either participating class, such as 'time interval₁ is before time interval₂', are mapped to associations in which both association ends are owned by the association.
- Verb concepts with more than two roles map to UML classes stereotyped as «verb concept». The roles in these verb concepts are modeled by UML associations from the «verb concept» class to the UML classes that model the ranges of the roles. These associations are stereotyped «verb concept role» and are properties of the «verb concept» class. These properties always have multiplicity 'I', because each instance of the class represents a single instance of the relationship, having exactly one participant in each role. The multiplicity of the association-owned end of a «verb concept role» association represents the number of situations in which a given object in the range class can play that role.
- In general, the operation is named for the primary verb concept wording, and is attached to the class that is the range of the subject role in that wording. The operation takes one argument for each other role in the verb concept wording and returns a Boolean result. The Boolean result indicates whether the subject instance ("self"), together with a given set of argument values as participants in the corresponding association roles, represents an actual instance of the association. In addition, in those cases where it is convenient for stating rules, a synonymous form of the verb concept is used to create an operation on the class that is the subject of that form. That operation is named for the synonymous form, and its arguments correspond to the remaining roles in the synonymous form. It returns Boolean with the same interpretation.
- Some verb concepts that have more than two roles also map to a UML operation that returns the unique object that plays one of the roles, as a function of the objects that play the other roles. The operation is on the class that is the range of the subject role in one of the verb concept wordings, and that is one of the inputs to the function. The operation has one argument for each of the other roles that serves as an input to the function, and it returns the unique object that plays the remaining ("result") role in the corresponding state of affairs. For example, the verb concept 'duration₃ = duration₁ plus duration₂ has the synonymous form ''duration₁ plus duration₂ gives duration₃. This latter form is mapped to an operation on class 'duration' plus(duration2: duration): duration which returns the value of 'duration3.
- All formal SBVR definitions and rules (Necessities) in Clauses 8 and 16 are also formally specified as OCL definitions and constraints. The "noun forms", if any, of the verb concepts in those sections are mapped to UML Properties or Operations, and those Properties and Operations have formal definitions in OCL.
- Definitions, notes, and examples that are attached to entries in the Date-Time Vocabulary are intentionally omitted from the UML model to avoid the requirement to maintain consistency between the specification text and ownedComments in the model.
- Because UML does not support the concept of Synonym (for a noun concept) or Synonymous Form (for a verb concept), the UML model does not include any formal model elements for those elements of the vocabulary.

For the definitions and rules in the Date-Time Vocabulary, this specification adds Object Constraint Language (OCL) rules to the UML model, to the extent possible. (The definitions of primitive concepts, and some rules, cannot be formally stated in terms of classes and associations in the model.)

OCL constraints are incorporated into the document text and the UML model as follows:

Deleted: Binary verb concepts that do not map to properties, and verb concepts with more than two roles, also map to UML operations on one or more of the participating classes. This enables Object Constraint Language (OCL) expressions (see below) to exploit the associations as functions. Each such verb concept maps to an operation on at least one of the participating classes. The operation takes one argument for each role and returns a Boolean result. The Boolean result indicates whether a given set of argument values, as participants in those roles, represents an actual instance of the association. The operation is named for the verb concept form, omitting the placeholder for the subject role (the class to which it is attached)

Deleted: Some verb concepts with more than two roles also map to UML operations that are assigned to one participating class (role), take arguments that represent the objects that play all but one of the other roles, and return the object that play s the remaining role. For example, 'durations' = duration | plus durationg' maps to an operation on class' duration! plus(duration): duration, which returns the value of 'duration3'

Commented [EB1]: Issue 13-13 REPLACE text

Deleted: All operations defined for UML classes by this specification are formally specified by OCL definitions.

• Each fully-formal SBVR definition has an equivalent OCL definition or constraint, captioned as "OCL Definition:".

The constraint captures the distinguishing characteristics of the formal definition. For example, if the formal definition of an SBVR object type 'luxury car' is 'carthat is gold,' the corresponding OCL constraint is given as:

OCL Constraint:

context 'luxury car'

inv:self._'is gold'

- Each SBVR Necessity (that is not a cardinality constraint) has an equivalent OCL constraint, captioned as "OCL Constraint"
- Necessities and Possibilities that specify cardinalities are modeled as UML cardinalities, rather than OCL constraints
- OCL name-quoting syntax is applied as necessary to quote UML names with embedded spaces. For example the
 term 'consecutive sequence' is quoted in OCL as "_'consecutive sequence'".

OCL is provided for sub clauses 8.1, 8.2, and Annex D. These parts of the specification require the most rigorous definition.

5.4 CLIF Axioms

This specification includes a file of matching and normative Common Logic Interchange Format (CLIF) axioms that is inventoried in Annex A. The axioms are provided to precisely specify the formal Definitions and Necessities of this specification in a form that is meaningful to logicians and that can be input (in the future) to software that automatically checks for consistency among the axioms. The CLIF axioms in this document have been syntactically checked using the Kojeware CLIF validation service that is available at http://www.kojeware.com/clif-file-validator. No automated quality analysis has yet been performed.

The CLIF axioms are derived manually from the SBVR-based text in this document. In case of any discrepancies between the SBVR-based text in this document and these axioms, the text prevails because it is the original model.

Names in the CLIF axioms are based directly on the corresponding SBVR names, using CLIF name-quoting as necessary to address embedded spaces. For example the SBVR term 'consecutive sequence' is quoted in CLIF as "consecutive sequence."

The file of CLIF axioms is derived automatically from CLIF statements that are incorporated directly in the text of this specification as follows:

Each fully-formal SBVR definition has an equivalent CLIF axiom, captioned as "CLIF Definition:". The axiom
defines how the corresponding concept is derived from some other concept. For example, if the formal definition of
an SBVR object type 'luxury car' is 'car that is gold,' the corresponding CLIF axiom is given as shown below.
 Read this as "each car is a luxury car if and only if the car is gold."

CLIF Definition: (forall ((car car)) (iff ("luxury car" car) ("is gold" car))

Each SBVR Necessity has an equivalent CLIF axiom, captioned as "CLIF Axiom:". The axiom expresses the same
constraint as the SBVR Necessity.

Many SBVR Necessities specify cardinality constraints. Basic CLIF cannot express these constraints in the absence of functions that generate collections, give the cardinality of collections, and compare the values of integers. Therefore this specification assumes the following in order to express cardinality constraints in CLIF:

• For each SBVR verb concept, there is a corresponding CLIF predicate, and also n-1 CLIF functions, where n is the number of roles of the verb concept. The predicate and all the functions have the name of the verb concept, quoted if necessary. The distinction among them is the number of terms they take and which terms they take. The predicate takes one term for each role of the verb concept, and returns true or false according to whether the verb concept is satisfied for the specific terms. Each function omits one role and produces a collection of instances that fulfill that

role in relationship to the other terms of the function.

For example, given an SBVR verb concept 'drives car to city,' the predicate ("driver drives car to city" John "car 123" Paris) is true or false according to whether John drives car 123 to Paris. The function ("driver drives car to city" John Paris) returns the collection of cars that John drives to Paris.

- A primitive count function that returns the cardinality of a collection. For example, (count ("driver drives car to city" John Paris)) produces the number of cars that John drives to Paris.
- CLIF defines the = predicate as testing whether two terms are equal. This specification uses primitive functions <, <=, >, >=, and + to mean the standard numeric relationships. For example (< (count ("driver drives car to city" John Paris)) 2) tests whether John drives fewer than two cars to Paris.
- · This document also uses the allDifferent function as defined in [IKL Guide].

CLIF is provided for sub clauses 8.1, 8.2, and Annex D. These parts of the specification require the most rigorous definition.

5.5 OWL Formulation

In addition to the normative SBVR, UML/OCL and CLIF specifications of the Date Time concepts, an informative model of the same concepts expressed in the Web Ontology Language (OWL) is provided. The OWL model -a set of OWL "ontologies"- was developed by a rote transformation from the Date Time vocabulary entries. The transformation converts the primary SBVR terms to OWL classes, properties, and individuals, and it converts each other element of an SBVR terminological entry to a specialized OWL annotation.

Each SBVR vocabulary presented in Clauses 8 through 17, and each supporting vocabulary presented in Annex D, was transformed to a separate OWL ontology in this way. The OWL ontologies are not presented in the specification per se. They are provided as an informative attachment to this specification in the standard OWL/RDF exchange form.

6 Additional Information

6.1 How to Read this Specification

This document serves different purposes for first-time readers versus implementers. First-time readers should start with informative Clause 7, "Rationale" that offers introductory text, and describes the motivations behind the design of this vocabulary. These readers may wish to refer to the normative clauses (Clause 8 through Clause 13), as well as informative Annex D, for definitions, notes, examples, and diagrams that describe the Date-Time Vocabulary concepts. The other Annexes provide additional examples and supporting information that should also be useful to these readers.

Implementers of this vocabulary will focus on the normative clauses and Annex D and on the supporting machine-readable files. The specific aspects of interest will depend upon the intended conformance goal, as described in Clause 2. Implementers should study the material in the normative clauses in detail. The supporting informative material will also provide some guidance.

6.2 About this Specification

The first 6 clauses include information that is applicable to most OMG specifications. The rest of the document includes the following key topics:

Clause 7 - Rationale (informative) - introduces this document and discusses some of the key technical choices made by this specification.

Clause 8 - Time Infrastructure (normative) - describes fundamental concepts about <u>time intervals</u>, <u>durations</u>, and their relationships.

Clause 9 - Duration Values (normative) - <u>Duration values</u> are amounts of time stated as multiples of <u>time units</u>, for example "<u>5 hours 30 minutes</u>". The model of <u>duration values</u> presented here accommodates the complexities introduced by the varying number of <u>calendar days</u> in each <u>calendar month</u> and <u>calendar year</u>.

Clause 10 - Calendars (normative) - defines the basic concepts used to organize time as <u>time scales</u> and <u>calendars</u>, and to identify locations in time via <u>time coordinates</u>, such as "<u>July31</u>".

Clause 11 - Gregorian Calendar (normative) - defines the standard <u>Gregorian calendar</u>, and the <u>time points</u>, <u>time scales</u> and <u>time coordinates</u> of this <u>calendar</u>.

Clause 12 - ISO Week Calendar (normative) - defines the standard calendar based on weeks, and the time points, time scales, and time coordinates of this calendar.

Clause 13 - Time of Day (normative) - specifies the <u>time points</u>, <u>time scales</u>, and <u>time coordinates</u> that jointly identify the <u>time periods</u> within a day.

Clause 14 - Internet Time (normative) - specifies the calendar used by the Network Time Protocol.

Clause 15 - Indexical Time (normative) - Indexical time concepts use terms such as "in the past" and "now" to refer to time. These terms are defined in this specification, despite their inherent ambiguity, because they are frequently used in everyday communication.

Clause 16 - Situations (normative) - provides concepts that relate situations to time.

Clause 17 - Schedules (normative) - defines time tables, and schedules of events that may repeat over time.

Clause 18 - Interchange of Duration Values and Time Coordinates (normative) - defines how <u>duration values</u> and <u>time coordinates</u> should be exchanged between tools that implement this specification. The interchange format is based on the existing [XML Schema] and [ISO 8601] specifications.

Annexes

Annex A: Attachments (normative) - Lists the machine-readable files that accompany this specification.

Annex B: References (informative) - this annex lists the standards documents and academic papers that were consulted in the preparation of this specification.

Annex C: Business Usage Guidelines (informative) – is published as a separate document for the convenience of business users who need not read the normative specification. This annex offers counsel on the use of DTV by a discussion of and examples of "calendar expressions", and an inventory of the Date-Time noun and verb concepts recommended for business

Annex D: Fundamental Concepts (normative) - International standards, for example [VIM], [ISO 80000:3], and [ISO 18026] define duration as just one of many quantity kinds, and time scales as one of many kinds of coordinate systems. This permits the formation of derived quantities based on durations (e.g., velocity, which is length / duration), and multi-dimensional coordinate systems that include time as one dimension. Coordinate systems themselves depend upon mathematical concepts, such as sequences and scales. Unfortunately, there is no existing SBVR vocabulary or ODM ontology that addresses these concepts. The authors recognize that they are out-of-scope for this specification, but felt it necessary to imagine how this Date-Time Vocabulary would fit into a complete schema that addresses them. Annex D summarizes that schema in the form of several SBVR vocabularies.

Annex D.2: Sequences (normative) - presents a complete model of $\underline{\text{sequences}}$ that provides the formal foundation for time $\underline{\text{scales}}$

Annex D.3 Quantities Vocabulary (informative) - defines a minimal vocabulary for <u>quantities</u> and <u>units of measure</u>. This vocabulary is informative because it does not address requirements beyond those of this Date-Time Vocabulary.

Annex D.4: Mereology (normative) specifies a basic model of mereology that provides the formal basis for the part-of relationship among time intervals.

Annex E: Formalizing English Tense and Aspect (informative) - The normative clauses of this specification deal with the semantics of time as used in natural languages. This Annex describes how propositions that are given in English language syntax may be formulated using the Date-Time Vocabulary.

Annex F: This annex formally lists the vocabularies provided by the Date-Time Vocabulary specification.

Annex G: UML Profile for the SBVR Elements used in the Date-Time Vocabulary (normative) - documents the stereotypes used in the UML model of this vocabulary.

Index of Date Time Designations (informative) - contains an index to the business designations defined in this document.

6.3 Structure of this Specification

Figure 6.1 summarizes the structure of the SBVR vocabularies and UML packages that are defined in this specification.

The SBVR-DTV package contains the concepts from the SBVR specification that are used in this specification. The corresponding excerpts from the SBVR vocabularies are specified in Clause 4. The SBVR Profile defines UML stereotypes for some of these SBVR concepts. These stereotypes are used to mark up UML representations of some DTV concepts as described in Annex I. The «apply» relationship provides the Profile as the interpretation of those markups in the SBVR-DTV package, and in every UML package that directly or indirectly imports the SBVR-DTV package.

The content of each remaining element of the figure is a vocabulary and a UML package that corresponds to a top-level clause of this specification, or to a sub-clause of Annex D. The dependency relationships shown in the figure match the dependency relationships among the corresponding specification clauses.

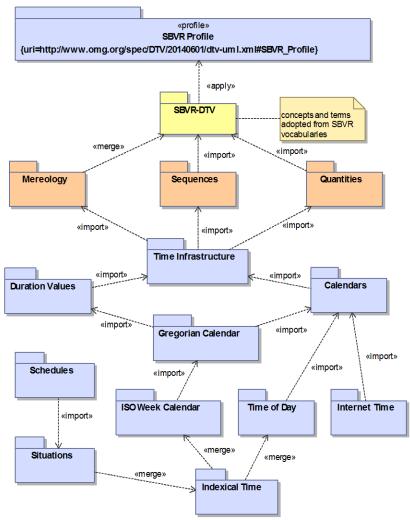

Figure 6.1 - SBVR Vocabulary and UML Package Structure

The «import» relationship shown in Figure 6.1 indicates both SBVR '<u>vocabulary</u>1 *incorporates* <u>vocabulary</u>2' (as indicated by the 'Included Vocabulary' caption) and UML package import. For both SBVR and UML, the entire contents of the imported package are incorporated into the importing package. For example, the <u>Duration Values</u> vocabulary incorporates the <u>Time Infrastructure</u> vocabulary, and the corresponding Duration Values UML package imports the Time Infrastructure UML package.

Vocabulary incorporation and UML package import are both transitive. For example, the $\underline{\texttt{Calendars}}$ vocabulary and package indirectly import the $\underline{\texttt{Sequences}}$ vocabulary and package.

The «merge» relationship used in Figure 6.1 is UML "package merge." This means that the entire contents of the merged package are incorporated into the merging package and some elements of the merged package are modified by the merging package. For example, the Indexical Time package merges the Calendars package, and thus the Time Infrastructure package, because Indexical Time adds UML attributes (such as the 'is current' attribute that represents the concept 'time interval' class defined in the Time Infrastructure package.

SBVR does not distinguish vocabulary incorporation from 'vocabulary merge,' because what is added is just additional vocabulary or additional constraints. So the 'merge' relationships shown in Figure 6.1 are accomplished by vocabulary incorporation in the SBVR text in this specification.

7 Rationale

7.1 General

This Informative clause introduces this document, and discusses various design considerations that impacted it.

7.2 Multiple Goals

This vocabulary attempts to satisfy several goals that tend to conflict.

- Provide a Standard Business Vocabulary for Date and Time Concepts Provide a vocabulary of date and time
 concepts that business users can share and exploit in their business domain vocabularies and rules. Quoting Donald
 Chapin, this requires an "...SBVR Foundation Business Terminology that is conceptualized optimally for the way
 people think and communicate about things in their organizations using natural language." To satisfy this goal, the
 date and time vocabulary needs to include terms that make intuitive sense to business users.
- Support Machine Reasoning about Time Provide a formal ontology that enables machine interpretation and reasoning. This means that processing by automated reasoners is possible, based on a well-grounded formal

representation. For example, it should be possible for a reasoning system to determine whether a payment is more than 30 days late compared to some due date. Satisfying this goal requires carefully-defined vocabulary concepts, to the point of making distinctions that would not occur to business users. The business vocabulary is grounded on the formal ontology, so these distinctions show through in the business vocabulary.

Enable implementation - Enable tool vendors and other software developers to implement the date and time
vocabulary with a "reasonable" amount of development effort — meaning that the value obtained is commensurate
with the development cost. That cost is driven by the size of the vocabulary — the more there is to implement, the
greater the cost. Implementation cost is also driven by the effort required to resolve ambiguities, omissions, and
inconsistencies in the specification. Including a formal grounding and concise vocabulary is expected to facilitate
both development of tools and use of the specification by vendors, business users, and those who want to apply
formal reasoning systems.

This specification employs several techniques to reconcile these different modeling goals. The vocabulary is presented as an SBVR business vocabulary, with extensive examples and notes. Many formally-defined concepts are also presented in CLIF and OCL. Wherever possible, terms and examples are chosen to make sense to business users. Parallel construction of terms ensures that related terms are used consistently. Every concept is precisely defined. Multiple distinct concepts are defined where needed to distinguish between concepts that are intuitively similar but have different reasoning implications.

Annex D, "Foundational Concepts" documents general concepts that, though out-of-scope for a date and time vocabulary, nevertheless must be implemented consistently by reasoning systems. Annex D includes formal mathematical definitions of sequences, on which all scales, not just time scales, are based, and a general treatment of quantities and units, and of basic mereology. Although Annex D is not normative, it will provide guidance that should ease formal integration of future possible normative specifications, perhaps published by the OMG or other standards bodies, of the Annex D concepts with the normative vocabulary of this specification. Implementers of this specification are encouraged to support or assure compatibility with Annex D. Normative concepts of this specification that specialize Annex D concepts formally includes Annex D concepts in their definitions, as if Annex D were normative.

Implementors and reasoning systems are also addressed by providing this date and time vocabulary in SBVR, UML, and CLIF forms.

7.3 Reckoning of Time

The scientific community, and some time standards such as OWL-Time, typically conceive of time as continuous, meaning that any moment of the <u>Time Axis</u> can be subdivided into an infinite number of smaller moments. This Date and Time Vocabulary follows that pattern by modeling time as a segment of the <u>Time Axis</u> called a <u>time interval</u>, and describing amounts of time as durations.

Mathematically, both <u>time intervals</u> and <u>durations</u> correspond to contiguous sets of real numbers, making modeling of time-varying phenomena amenable to continuous mathematics. This specification gives a rigorous account of the operations that may be performed on <u>time intervals</u> and <u>durations</u>, providing the basis for formal reasoning about time.

Since antiquity, the passage of time has been reckoned by counting discrete time intervals demarcated by the diurnal and annual cycles of the Earth and the Moon's cycle – giving rise to 'time point' concepts such as 'calendar day, 'calendar month', and 'calendar year'. To identify a particular element of a cycle, each cycle is mapped onto a 'calendar'.

Calendars define time scales used refer to time points by name or by scale index. The combination of a time scale and an index or a name (e.g., 'February') is called a 'time coordinate'. An individual time coordinate is called an 'atomic time coordinate', whereas combinations of time coordinates (e.g., "February3") are called 'compound time coordinates' (sub clauses 7.5 and 10.6.3). Time coordinates provide a reference scheme for time points via the verb concept 'time coordinate indicates time point'. Thus time points can be referred to either by definition descriptions (e.g., "the day after the meeting") or by time coordinates (e.g., "3:00 p.m.").

Each <u>time point</u> is a concept whose instances are <u>time intervals</u>. Thus, every '<u>time interval</u>' fact type role in this specification can be filled by a <u>time coordinate</u> that <u>indicates</u> a <u>time point</u>. For example, the statement "the meeting time

is before 3:00 p.m." uses the "time interval₁ is before time interval₂" verb concept (sub clause 8.2.2) to compare one time interval given as a definite description with another time interval given as a time coordinate.

Many <u>calendars</u> have been devised, ancient and modern. <u>Time coordinates</u> of most <u>calendars</u> can be correlated to jointly reference the same <u>time interval</u>. <u>Calendars</u> are anchored to the <u>Time Axis</u> by associating a noteworthy event with a particular <u>time point</u> on the <u>calendar</u>, e.g., the signing of the <u>Convention du Mè tre</u> in Paris on <u>May 20, 1875</u>, which established the International Bureau of Weights and Measures (BIPM), and is the anchoring event for the modern <u>Gregorian Calendar</u>.

Timekeeping is significantly complicated by the incommensurable and irregular periods of rotation and revolution of the Earth and Moon. These variations are accounted for at the <u>granularity</u> of '<u>day</u>' by incorporating intercalary leap days in the <u>Gregorian Calendar</u>, and at the <u>granularity</u> of '<u>second</u>' by incorporating intercalary <u>leap seconds</u> in <u>UTC</u>. Businesses sensitive to elapsed '<u>seconds</u>' should use <u>TAI</u>, while those that are concerned with calendar alignment may prefer <u>UTC</u>.

Time is measured by clocks, or tracked by <u>calendars</u> in discrete <u>time intervals</u> called '<u>time periods</u>', which <u>instantiate</u> time point sequences, as discussed in the next subclause. A particular <u>member</u> of a <u>time scale</u> – and a <u>time period</u> that <u>instantiates</u> a <u>time point sequence</u> of just one <u>member</u> – is called a '<u>time point</u>'. Every <u>time scale</u> divides the <u>Time Axis</u> into <u>time points</u> with a specified <u>duration</u>, called the '<u>granularity</u>' of the <u>time scale</u>. One consequence of this model is that every <u>time period</u> is aligned to the <u>time points</u> of a <u>time scale</u>: the <u>time period</u> <u>stants</u> on the <u>first time point</u> of some <u>time point</u> of some <u>time point</u> of some <u>time point</u> sequence of the <u>time scale</u>, and the <u>time period</u> ends on the <u>last time point</u> of some <u>time point</u> sequence of the <u>time scale</u>. Another consequence is that the <u>duration</u> of every <u>time period</u> is a multiple of the <u>granularity</u> of the <u>time scale</u>.

Of course, any <u>time point</u> can be subdivided by another <u>time scale</u> with a finer <u>granularity</u>. For example, a <u>time point</u> with <u>duration</u> "<u>1 second</u>" can be divided into <u>milliseconds</u>. But subdivision in this sense is still a discrete process. The finer <u>time scale</u> has a finite number of <u>time points</u> for each <u>time point</u> on the original <u>time scale</u>.

In everyday activity, people and businesses talk about <u>durations</u> such as <u>years</u> and <u>hours</u>, and about <u>time periods</u> such as <u>calendar years</u>, <u>hours of day</u>, and so forth. These discrete time concepts are used in ordinary conversation, in business contracts, in legislation and regulations, and in corporate policies. They also form the basis for identifying <u>time intervals</u> for scientific purposes (International Atomic Time) and for navigation (Global Positioning System). Representation of time in computers is inherently discrete and finite. Consequently, this specification also defines discrete time modeled by <u>time</u> <u>scales</u>.

7.4 Time Scales

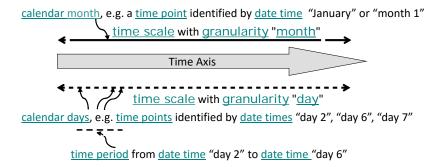

Figure 7.1 - The Time Axis and Time Scales

Following [ISO 8601], this specification considers that there is a single <u>Time Axis</u> that is measured by multiple <u>time scales</u>. The <u>Time Axis</u> represents "the succession in time of instantaneous events". Figure 7.1 shows the <u>Time Axis</u> with one <u>time scale</u> for <u>calendar months</u>, and another for <u>calendar days</u>.

Each <u>time scale</u> comprises a <u>consecutive sequence</u> of <u>time points</u> at regular or irregular <u>time intervals</u>. The <u>time points</u> of each <u>time scale</u> have a <u>duration</u> that is called the <u>granularity</u> of the <u>time scale</u>. Month scales have irregular time intervals because different <u>calendar months</u> have different <u>durations</u>. Thus, the <u>Time Axis</u> is continuous time, while <u>time scales</u> partition the <u>Time Axis</u> into discrete segments. <u>Time scales</u> define concepts that are meaningful in business and everyday life.

Time coordinates label individual time points on a time scale. For example, the top time scale in Figure 7.1 has a calendar month labeled "January", while "day2", "day6", and "day7" are indicated on the time scale for calendar days. A time coordinate can have multiple labels. For example, "January" is also labeled "month1".

A <u>time period instantiates</u> a <u>time point sequence</u>, a sequence of consecutive <u>time points</u> on a <u>time scale</u>.

"Instantiation" means that the <u>time point sequence</u> <u>corresponds to</u> the <u>time period</u>, analogous to SBVR's "<u>meaning corresponds to thing</u>". Each <u>time point sequence</u> has a <u>first time point</u>, a <u>last time point</u> (the final <u>time point</u> of the <u>time point sequence</u>), and a <u>duration</u> (the length of the <u>time period</u>). For example, the <u>time point sequence</u> from "<u>day 2</u>" to "<u>day 6</u>" has a <u>first time point</u> of "<u>day 2</u>", a <u>last time point</u> of "<u>day 6</u>", and a <u>duration</u> of "<u>5 days</u>".

Conventionally, and by international agreement, on some <u>time scales (hours, minutes)</u> the first <u>time point</u> is designated "<u>hour 0</u>" or "<u>minute 0</u>", while on others (<u>months, weeks, days</u>) the <u>first time point</u> is designated "<u>month1</u>", "<u>week1</u>", or "<u>day1</u>". Historically and in [XML Schema], <u>calendar years</u> are numbered from 1 but scientific practice and [ISO 8601] counts a year 0.

Conversion between <u>time scales</u> is possible via formulae that specify how a <u>time point</u> on a coarser <u>time scale</u> indicates the same <u>time interval</u> as a <u>time period</u> on a finer <u>time scale</u>.

7.5 Distinctions

The distinction among <u>time coordinate</u> and <u>duration values</u> is significant. A <u>time coordinate</u> gives a location on a <u>time scale</u>. A <u>duration value</u> specifies an amount of time. For example, a meeting might occur at "3:00 p.m." (a <u>time coordinate</u>) for "3 <u>hours</u>" (a <u>duration value</u>). This distinction leads to separate terms for concepts such as "<u>day</u>" (a <u>time unit</u> used with <u>duration values</u>) and "<u>calendar day</u>" (a <u>time point</u> indicated by a <u>time coordinate</u>).

There is a many-to-one relationship between time coordinates and time points. For example, "January 2009" and "month 1 of 2009" are two time coordinates for the same time point. In SBVR terms, time coordinates provide the reference scheme for time points. In human language, a thing and a reference to the thing are often not distinguished, but the difference is important in ontological reasoning.

Similarly, there is a many-to-one relationship between <u>duration values</u> and <u>durations</u>. "<a href="mailto:linear: 150minutes" are two <u>duration values</u> for the same <u>duration</u>. Again, the distinction is significant ontologically but often blurred in human discourse.

7.6 Compound Time Coordinates

Compound time coordinates are time coordinates composed from multiple time scales. Compound time coordinates are used to designate a time interval whose duration is much less than the span of a time scale. For example, to identify a particular calendar day on a time scale that spans millennia, the compound designation "3 January, 2010" is used, rather than something like "day733795". Compound time coordinates originated historically as counts of the apparent cycles of the Sun, the Moon, and the stars.

Around the globe, different cultures express compound time coordinates in different ways. For example, "January3,2010", "January2010", "Janua

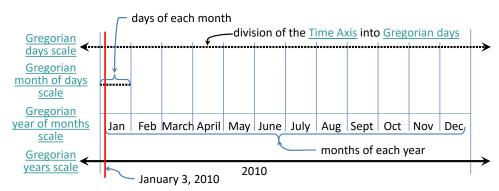

Figure 7.2 - Example of Gregorian calendar

This specification models "2010" as a <u>time coordinate</u> (a date time, or <u>timestamp</u>) on the <u>Gregorian years scale</u>. It models "3 <u>January 2010</u>" as a <u>compound time coordinate</u> that references multiple <u>time scales</u> of the <u>Gregorian calendar</u>. The <u>compound time coordinate</u> specifies <u>time points</u> on the <u>Gregorian years scale</u>, the <u>Gregorian year of months scale</u>, and the <u>Gregorian month-of-days scale</u>. Put together, these <u>time points</u> on these <u>time scales</u> indicate (by definition of '<u>compound time point</u>') a particular <u>time point</u> on the <u>Gregorian days scale</u>.

Notionally, the <u>Gregoriandays scale</u> is a time scale of granularity '<u>day</u>' that extends indefinitely into the past and the future. "<u>3 January 2010</u>" can be understood as the <u>time interval indicated by</u> a particular <u>time point</u> on the <u>Gregoriandays scale</u>. Sub clause 10.6.2 gives details about this. Sub clause 10.8 gives details about conversions between <u>time scales</u>.

Not all <u>time scales</u> can be combined in <u>compound time coordinates</u>. For example, "<u>day33 second 45</u>" makes no sense. Clauses 11 through 13 details both the <u>time scale</u> combinations that form legitimate <u>compound time coordinates</u> and their meaning in terms of <u>atomic time coordinates</u>. For example, "<u>01:35</u>" is a <u>compound time coordinate</u> (using the <u>day of hours scale</u> and the <u>hour of minutes scale</u>) that means <u>minute of day 95</u> on the <u>day of minutes scale</u>.

The meaning of some <u>compound time coordinates</u> as <u>time intervals</u> depends upon the presence or absence of leap days. For example, the relationship of <u>March</u>, <u>April</u>, etc. on the <u>Gregorian year of months scale</u> to the <u>Gregorian days scale</u> depends upon the number of days in <u>February</u>. In <u>leap years</u>, there is an additional day in <u>February</u> that "bumps" <u>March</u> over by one day on the <u>Gregorian days scale</u>. Hence, a <u>compound time coordinate</u> such as "<u>3 March</u>" does not mean a single <u>Gregorian day</u> on the <u>Gregorian days scale</u> if the <u>calendar year</u> is not given. Instead, such a date is understood as a choice among two possible <u>Gregorian days</u>. The choice is called a "<u>time set</u>" and denoted (in this example) as "<u>Gregorian day63</u>, <u>Gregorian day63</u>)".

7.7 Compound Duration Values

Compound duration values are duration values composed from multiple time units. Examples are "3 weeks 4 days", and "1 hour 30 minutes". The meaning of these is durations using the smallest time unit of the compound duration values. For example, "3 weeks 4 days" means "25 days", and "1 hour 30 minutes" means "90 minutes".

Some compound duration values that use nominal time units are ambiguous. For example, "5 months 3 days" is ambiguous because the number of Gregorian days in a Gregorian month of year varies. Similarly, the number of Gregorian days in a Gregorian year varies according to whether the Gregorian year is a leap year. The concept 'duration value set' models the ambiguity. For example, "2 years 1 day" means the duration value set [730 days, 731 days].

7.8 Granularity of Time Coordinates and Time Points

The <u>granularity</u> of a <u>time coordinate</u> is understood as the finest <u>granularity</u> of the components of the <u>time coordinate</u>. For example, the <u>granularity</u> of "<u>3 January 2010</u>" is '<u>day</u>'. This is important when understanding the meaning of a phrase such as "the meeting happens on <u>3 January 2010</u>". The phrase means that the meeting happens sometime during that <u>calendar day</u>, but does not say whether it happened at noon or <u>18:00</u> or throughout the entire <u>calendar day</u> because the <u>granularity</u> means the whole day. A phrase such as "the meeting happens at <u>18:00 3 January 2010</u>" is more specific because it uses a <u>compound time coordinate</u> with <u>granularity 'hour'</u>. It means that the meeting happens sometime within the hour indicated by "<u>18:00</u>". To specify the time more precisely, add minutes or seconds or even fractional seconds to the <u>compound time coordinate</u> to achieve the desired temporal resolution. The granularity chosen in giving a <u>time</u> <u>coordinate</u> should be as specific as required for any particular use case.

Similarly, the <u>time unit of a compound duration value</u> is the least <u>time unit of the individual atomic duration values</u> that makeup the whole <u>duration value</u>. For example, "<u>6 hours 00 minutes</u>" has a <u>time unit of "minute"</u>, while "<u>6 hours"</u> has a <u>time unit of "hour"</u>.

7.9 Time Point Relationships

This specification provides relationships among <u>time points</u> and <u>durations</u> that permits comparing, adding, and subtracting them in various combinations. These are described in Clause 8 in terms of fundamental relationships (e.g., the mereological aspects of <u>time intervals</u>, the *is before* relationship between <u>time intervals</u>, the Allen relations), and various derived relationships.

Some <u>duration value</u> relationships, when applied to operands that have <u>nominal time units</u>, may have no meaning. For example, it makes sense to compare two <u>duration values</u> that are in <u>months</u> with each other (e.g., "<u>5months</u> is greater than <u>3 months</u>"), but comparing some <u>duration values in months</u> to some <u>duration values in days</u> (e.g., "<u>2 months</u> is less than <u>59 days</u>") may be meaningless since <u>months</u> have varying numbers of <u>days</u>. Whether a relationship has meaning may depend upon both the <u>values</u> and <u>time units</u> of the relationship operands. For example, "<u>10 days</u> is less than <u>1 month</u>" is always true, even though individual <u>Gregorian months</u> may be <u>28</u>, <u>29</u>, <u>30</u>, or <u>31 Gregorian days</u>. Clause 15 addresses these issues.

Similarly, time relationships may be ambiguous when applied to <u>time coordinates</u> or <u>time points</u>. For example, the <u>time interval</u> from <u>8 January</u> through <u>13 March</u> (given without the <u>Gregorian year</u>) has one of two <u>durations</u>, the <u>duration value set</u> (65 days, 66 days). Clause 16 discusses these complexities.

7.10 Temporal Reasoning

A major goal of the Date-Time vocabulary is to enable reasoning about time in fact models. Such reasoning presupposes that the temporal aspects of each sentence are described in the logical formulation of the sentence. This sub clause provides a summary of issues involved and describes how this specification supports temporal reasoning. A more thorough treatment is provided in sub clause 16.5.

Fundamentally, time is associated with events and with the lifecycle of things. This specification uses the term "situation" to refer to events, activities, states, etc. Linguists often categorize situations in various ways, for example as "events," "situations," actions, and so forth. This specification chooses not to categorize situations, but instead to focus on various relationships between situations and time.

Situations are said to *occur*, which is a primitive notion. Some situations that are conceptualized never occur. This specification uses the term 'occurrence' for a situation that occurs at some time in the world that is taken to be actual. When one is making a decision in the real world, what is taken to be actual is what the decision maker knows or believes about the real world. When one is analyzing a what-if situation (as in a business plan), the hypothetical elements of that situation are taken to be 'actual.'

When something occurs, there is always a time associated with the <u>occurrence</u>. The time may be present, past, or future, relative to the decisions being made. This permits distinctions among different instances of some situations that recur. For example, "Oceanic Air flight 815 flies from NY to Los Angeles" may be a situation that occurs many times and for which

the individual <u>occurrences</u> may be distinguished by time. However, many types of occurrences are not distinguishable by time. For example, multiple child births often happen at the same time, so are not distinguishable purely by time.

The basic element of time introduced in Date-Time is a <u>time interval</u>, a portion of time having a non-zero <u>duration</u>. One basic fact type relates occurrence to <u>time interval</u>: '<u>occurrence occurs throughout time interval</u>'. It represents the idea that the <u>occurrence</u> is ongoing at every point in the <u>time interval</u>. From it, we derive the characterizing relationship '<u>occurrence occurs for time interval</u>' (sub clause 16.2). This fact type represents the idea that the <u>occurrence</u> starts at the beginning of the <u>time interval</u> and ends at the end of that <u>time interval</u>. For any <u>occurrence</u>, there is exactly one such time interval, called the <u>occurrence</u> interval.

A <u>situation kind</u> is a potential situation that could occur in some <u>possible world</u>. In a given world of interest (the world taken to be actual), each <u>situation kind</u> has zero, one, or more <u>occurrences</u>. We say that an <u>occurrence exemplifies</u> a <u>situation kind</u>. The <u>situation kind</u> itself is said to <u>occurrence</u> time interval that is the <u>occurrence interval</u> of an <u>occurrence</u> of the <u>situation kind</u>. Other verbs that relate <u>occurrences</u> to <u>time intervals</u> are used to relate <u>situation kinds</u> to <u>time intervals</u> by extension. The critical difference is that an <u>occurrence</u> is a single actual situation and <u>occurs for</u> exactly one <u>time intervals</u>, a <u>situation kind</u> is an abstraction of zero or more <u>occurrences</u> and may <u>occurfor</u> zero or more <u>time intervals</u>, one for each distinguished <u>occurrence</u>.

Occurrences are partially ordered by the times of their occurrence – their occurrence intervals. This specification provides the basic vocabulary to describe the ordering of occurrences in sub clause 16.3. Ordering of occurrences allows some statements to be made about the ordering of situation kinds, and those verbs are defined in sub clause 16.5.

This document uses 'proposition' to mean the logical interpretation of a sentence. Each proposition (that is not paradoxical) corresponds to exactly one situation kind. This viewpoint was famously championed by Donald Davidson, that a proposition is a definite description of a situation ([Davidson], p. 504). This specification adopts this viewpoint. A proposition is either true or false in a given world. A situation kind either has or does not have occurrences in the universe of discourse. There is a duality in that a proposition may simultaneously have a truth value and correspond to a situation kind. A proposition is true when it corresponds to a situation kind that has at least one current occurrence.

Since a <u>proposition</u> describes exactly one <u>situation kind</u>, it is said to <u>describe</u> every <u>occurrence</u> of that <u>situation kind</u> as well. In many cases, this is the critical fact type: <u>proposition</u> <u>describes occurrence</u>. For example, "the books of corporation XYZ are reviewed annually at corporate headquarters" can be formally represented as:

In every fiscal year (a business-defined <u>time period</u>), there is an <u>occurrence</u> that is described by the <u>proposition</u> "the books of corporation XYZ are reviewed", and that <u>occurrence</u> occurs at the corporate headquarters.

A <u>statement</u> contains explicit and implicit references to time that restrict the <u>time interval</u> of the situation it describes. Time is inescapable in a temporal model, it is pervasive. There is a <u>time interval</u>(s) associated with every fact statement, explicitly or implicitly. Explicit references are <u>time coordinates</u>, indexicals, and <u>definite descriptions</u>. References to time are implicit in the tense and aspect of verbs. This specification includes definitions of <u>time coordinates</u>, indexicals, and calendar terms used in statements, and formulations for the most common tenses and aspects.

Each example given above assumes that the relevant concepts are defined in domain-specific vocabularies. Such vocabularies include verb concepts, such as "flight takes off". Human languages use many different prepositions ("at," "on," "in," "during," etc.) for relationships with time. This specification supports verb concepts with a few of these prepositions, with the expectation that business vocabularies will define verb concepts using other prepositions as appropriate for particular business domains.

7.11 Temporal Granularity

The granularity of a time point is important to the semantic meaning of a statement such as " $\frac{\text{Apollo }13}{\text{April }1970}$ ".

Since we know from background knowledge that the launch took much less than a day, we understand this as "the occurrence 'Apollo 13 launched' happened within the specified calendar day". Public records show that Apollo 13 actually launched at "14:13 EST" on that day. But the statement "Apollo 13 launched on 11 April 1970" does not give any hours or minutes; it just gives the day. It tells us that the occurrence happened sometime during the day or perhaps

throughout the day. It tells us no more. If given as "Apollo 13 launched on 11 April 1970 at 14:13 EST", and assuming the launch took less than a minute, then we would know the time with minute granularity, that is that the launch happened within the specified minute of hour.

7.12 Language Tense and Aspect

Most human languages incorporate *tenses*, to indicate whether <u>propositions</u> occur in the past, the present, or the future with respect to the time of utterance of the <u>proposition</u>. For example, "<u>companyx traded with companyy</u>" is past tense. This specification captures the semantic meaning of tenses by associating <u>situation kinds</u> and <u>occurrences</u> with time and then indicating whether that time is past, present, or future with respect to <u>current time</u>. For example "<u>companyx traded with companyy</u>" is understood as "the <u>occurrence 'companyx trades with companyy</u>" is in the past". This approach to formalizing human sentences about tense follows [Parsons].

Many human languages also incorporate *simple*, *progressive*, and *perfect* aspects. *Simple aspect* applies to activities independent of whether they are ongoing or completed. For example "companyx traded with companyy", meaning that the two companies did trade, but does not say whether the trading is ongoing or completed. *Progressive aspect* means that an activity was ongoing or is ongoing or will be ongoing. For example "companyx was trading with companyy", meaning that the trading was continuing.

Perfect aspect indicates that an activity is accomplished. For example, "companyx will have traded with companyy" says that at some time in the future, the trading activity will be achieved. The difference between the simple and perfect aspects is shown by comparing the phrases "John writes a book" and "John has written a book". The second example, using "has written" applies the perfect aspect to indicate that the writing is complete. The first example, using "writes" uses the simple aspect. It does not say whether the writing is finished.

The progressive and perfect aspects may be combined to indicate that an activity both was ongoing, and is achieved. For example, "John has been writing a book" indicates that the writing occurred over time and the writing is completed or achieved.

In this specification, the progressive and perfect aspects are formally captured by characteristics of stuation.kind.continuing and stuation.kind.continuing and stuation.kind.continuing and stuation.kind.continuing may be progressive or not, and may be perfected or not. Both are independent of whether the stuation.kind.continuing is in the past, the present, or in the future.

Human languages enable combinations of tense and aspect. The following table gives a grammatical term and shows an example for each combination. The table assumes a domain vocabulary has a verb concept "company1 trades with company2". The table shows semantic concepts of tense and aspect using English syntax for illustration purposes only. Different natural languages use different syntaxes to express these semantics. Some natural languages do not distinguish each combination shown in the table. Annex E contains an informative formal analysis of English language syntax for tense and aspect.

Table 7.1 - Language Tense and Aspect

		Aspect			
		Simple	Progressive	Perfect	Progressive & Perfect
Tense	Past	past simple <u>companyx</u> traded with <u>companyy</u>	past progressive companyx was trading with companyy	past perfect, pluperfect companyx had traded with companyy	pluperfect progressive companyx had been trading with companyy

Present	present simple <u>companyx</u> trades with <u>companyy</u>	present progressive companyx is trading with companyy	present perfect companyx has traded with companyy	present perfect progressive companyx has been trading with companyy
Future	future simple companyx will trade with companyy	future progressive companyx will be trading with companyy	future perfect companyx will have traded with companyy	future perfect progressive companyx will have been trading with companyy

These combinations can be employed in business rules, as shown in these examples. They presume a domain vocabulary verb concept "company₁ merges with company₂".

- "If some company₁ merged with the company_x ..." asking whether a merger happened in the past, independent of whether the trading is ongoing, completed, or both.
- 2. "If some company₁ was merging with the company_x ..." asking whether a merger was continuing over some time in the past.
- 3. "If some company₁ will have merged with the company_x ..." asking whether a merger will be accomplished in the future.
- "If some company₁ will have been merging with the company_x ..." asking whether a completed merger will be ongoing in the future.

One intended use case for these many combinations is annotation of existing text, as in [TimeML].

Sub clause 16.9 provides vocabulary for formulating tenses and aspects, and describes how these may be combined in rules.

7.13 Domain Vocabularies and Time

This specification provides foundational date and time concepts that are intended for use in domain-specific business vocabularies and rules. Annex C gives a complete example. This sub clause shows an abbreviated example in order to introduce how a domain vocabulary can build on this Date-Time Vocabulary.

Consider the example of a contract that has a "start date," a "contract length," a "contract term," and a "payment schedule." A business vocabulary might specify these as follows:

Example Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

contract

Definition: Agreement between two companies for one to provide goods or services, and for the other

to pay for those goods or services

start date

General Concept: <u>calendar day</u>

Commented [EB2]: ty po

Deleted:

Note: The granularity of a domain vocabulary time concept is defined via the time point kind.

Defining 'start date' as a calendar day means that the granularity of 'start date' is 'day'

rather than 'week' or 'month', etc.

Note: Domain vocabulary time concepts should be defined as kinds of 'time point' or 'duration',

rather than 'time coordinate' or 'duration value'. Actual 'time points' and 'durations' can be specified as <u>definite descriptions</u> as well as 'time coordinates' and 'duration

values'.

contract has start date

contract length

General Concept: duration

Necessity: The granularity of 'contract length' is 'day'.

contract has contract length

contract term

Definition: Time interval during which the goods should be delivered or the services provided.

Necessity: The time interval of a contract is from the start date of the contract for the contract.

length.

contract has contract term

payment schedule

Definition: schedule for contract payments in which the time span is the contract term, and the

repeat duration is 1 month

contract has payment schedule

contract payment

Definition: amount to be paid according to the payment schedule

contract has contract payment

A business rule example might be:

It is obligatory that a contract payment be paid on each time table entry of the payment schedule.

The example is simplified since it does not specify all the details that would exist in a real contract. For example, it does not indicate who makes the payment or who receives the payment, nor does it allow for payments other than monthly. But it does illustrate some basic ideas:

- Defining domain vocabulary concepts that make use of <u>time points</u>(<u>start date</u>), <u>durations</u>(<u>contract length</u>), <u>time intervals</u>(<u>contract term</u>), and <u>schedules</u>(<u>payment schedule</u>).
- Using Definitions (<u>start date</u>, <u>contract term</u>, <u>payment schedule</u>) and Necessities (<u>contract term</u>) to precisely capture the semantic meaning of domain concepts.
- Specifying business rules that build upon this Date-Time Vocabulary and domain vocabularies to model business requirements.

Consider a business rule such as "It is obligatory that the <u>contract length</u> of <u>each contract</u> is less than <u>1 year</u>." Notice that it compares '<u>contract length</u>' to '<u>1 year</u>'. It does not quantify over '<u>year</u>' because time is a mass noun concept. In

contrast, a rule such as "It is obligatory that each rental has at most 3 additional drivers" uses quantification because 'additional driver' is a countable noun concept. Mass noun concepts are measured (possibly in fractional units of measure) while countable noun concepts are counted in whole units.

7.14 Enabling Other Calendars

The world has many different time-keeping and calendar systems. Specialized business calendars include fiscal calendars, tax calendars, and manufacturing calendars. Examples of historical, religious, and cultural calendars include the Julian calendar, various lunar calendars, and the 14-year calendar cycle of some Asian nations. Examples of time-keeping systems are those based on mariners' "bells", and religious "vespers".

This specification defines vocabularies for the standard, globally recognized "<u>Universal Date Coordinated</u>" (<u>UTC</u>) time system, and the <u>Gregorian Calendar</u>. In addition, this specification provides a <u>Time Infrastructure Vocabulary</u> that enables others to define business domain-specific, cultural, religious, or historical calendars and time schemas. The <u>Time of Day Vocabulary</u> and <u>Gregorian Calendar Vocabulary</u> show how time and calendar systems can be defined using the foundational concepts of the <u>Time Infrastructure Vocabulary</u>. Specifying time systems and calendars in terms of the foundational concepts of the <u>Itime Infrastructure Vocabulary</u> enables conversions between different calendars and different time keeping schemas.

7.15 Precise and Nominal Time Units

This specification distinguishes <u>precise time units</u> from <u>nominal time units</u>, as defined in sub clause 8.4. <u>Precise time units</u> are <u>measurement units</u> (Annex D.3.2) in the sense of VIM: <u>quantities</u> of <u>quantity kind</u> '<u>duration</u>' that are defined by convention. All <u>precise time units</u> are defined (sub clause 8.4) in terms of the SI '<u>second</u>': <u>picosecond</u>, <u>nanosecond</u>, <u>millisecond</u>, <u>microsecond</u>, <u>minute</u>, <u>hour</u>, <u>day</u>, <u>week</u>.

Two other time units—'month' and 'year'—are called 'nominal time units'. The duration of 'year' varies, depending upon whether a given calendar year includes a leap day. The duration of 'month' varies by definition. These time units are mentioned but not formally defined in [SI]. This specification formally defines these nominal time units (sub clause 8.4) in terms of sets of durations. For example, 'year' is defined as the set (365 days), 366 days). Sub clauses 11.5 and 11.6 develop algorithms that specify the meaning of multiples of these nominal time units. For example, 2 years is (730 days), 731 days), not (730 days, 732 days) because 2 calendar years contains just one leap day. This method enables well-defined results for comparisons such as "2 years > 730 days" and arithmetic expressions such as "4 years—3 months", which is (1369 days, 1370 days, 1371 days, 1372 days). This permits logical reasoning systems to infer results that otherwise would be unreachable.

Domain-specific vocabularies may define their own <u>precise time units</u> and <u>nominal time units</u> as required by particular business conventions.

7.16 Temporal Aspects of Rules

Broadly speaking, all business rules define, constrain, or guide situations in some way. Some rules require a temporal relationship among situations, for example forbidding two situations from occurring concurrently:

A person who is driving must not be texting.

SBVR Clause 10 states that rules apply to <u>possible worlds</u>, and that each <u>possible world</u> captures a '<u>fact population</u>'. As time progresses, the <u>fact population</u> evolves. Rules, such as the example given above, are evaluated with respect to an individual fact population at a specific time, the reference or <u>current time</u>.

In the example given above, the verbs 'is driving' and 'be texting' use the present progressive tense as described in sub clause 16.7: the activities are unfinished at some reference time interval. The "reference time interval" is understood to be any time that the rule is considered. This can be made explicit with the following wording, which is shown here to make the meaning clear. The previous phrasing is shorter, clearer, and recommended.

A person who is driving for some time interval must not be texting during the time interval.

Unless otherwise stated, rules apply at all times. To limit a rule to some <u>time interval</u>, a <u>behavioral rule</u> can state when it applies. For example:

After January 1, 2012, each expense that costs more than \$1,000 must be approved by a director.

The examples given above are all behavioral (deontic) rules: prohibitions and obligations. By their nature, structural (alethic) rules (necessities, impossibilities) apply to all times in all possible worlds, but they can still specify relationships among the times of situations. For example:

It is necessary that the birth date of each person is after the birth dates of the parents of the person.

The first two example rules, above, apply to <u>occurrences</u> of two different <u>situation kinds</u>. When behavioral and structural rules pertain to multiple <u>occurrences</u> of a <u>single situation kind</u>, the rules may be abbreviated. For example:

It is prohibited that a renter has possession of more than one rental car.

What is prohibited is a possible world in which a renter possesses multiple rental cars. This is equivalent to the following rule, which is not recommended because it is much more complex, and significantly harder to understand:

It is prohibited that a renter has possession of a rental car_1 at a time interval, and the renter has possession of a rental car_2 at a time interval, and time interval, overlaps time interval.

SBVR Clause 10 distinguishes between *static* constraints and *dynamic* constraints. Static constraints "impose[s] a restriction on what fact populations are possible or permitted, for each fact population taken individually." [SBVR sub clause 10.1.1.2] Dynamic constraints "impose[s] a restriction on transitions between fact populations." [ibid] The examples given above are static constraints. The previous example may also be stated as a dynamic constraint:

It is prohibited that a renter takes possession of a rental car₁ while the renter has possession of a rental car₂.

... where the verb concept 'renter takes possession of rental car' uses the simple present tense to identify an event and 'renter has possession of rental car' uses the present progressive tense to indicate an ongoing situation. See sub clause 16.9 for a discussion of the tense and aspect of verbs.

Domain modelers have the choice of writing static or dynamic constraints, but static constraints are recommended in SBVR because static constraints capture the complete business requirement, whereas dynamic constraints tend to address specific aspects of the business practice — possibly ignoring other aspects. In the last example, there might be other ways that a renter could end up possessing two rental cars, but the example rule only addresses one such way.

8 Time Infrastructure (normative)

8.1 General

Many time schemes and calendars are in use to support a variety of business needs, and due to historical, cultural, and religious traditions. The Time Infrastructure vocabulary provides a foundation for defining any time keeping or calendar system. Relating different time and calendar schemes to each other is made possible by using the foundational concepts provided in this clause.

8.2 The Time Axis and Time Intervals

The principal concept in this sub clause is time interval. This concept is used to define many of the business terms that are specified in other clauses of this specification. Formally, time interval is a primitive concept - an intuitive notion that does not have a mathematical definition. Its properties are defined by a set of axioms that are presented here as SBVR definitions and Necessities with matching CLIF and OCL statements. Much of this clause is the presentation of those axioms.

Time Axis

IEC 60050-111 ('time axis') Dictionary Basis: Dictionary Basis: IEC 8601 (2.1.1, 'time axis')

Definition: mathematical model of the succession in time of events along a unique axis

Source:

Definition: the indefinite continued progress of existence and events in the past, present, and future,

regarded as a continuum

Necessity: There exists exactly one Time Axis

The above necessity is questionable in light of the theory of relativity, but relativistic effects Note:

are not considered in this model. Some applications need to take these effects into account, e.g., GPS, in which the clocks in satellites are adjusted on the ground to compensate for relativistic shifts in their rates in orbit, due to the lower gravitational field in orbit (+) and

orbital motion (-).

Note:

<u>Time Axis</u> is the conceptual time dimension.
"Time" could be a synonym of <u>Time Axis</u>, but "time" is often confused with other concepts, Note:

such as duration and time of day.

time interval

Definition: segment of the time axis, a location in time

Note: Every time interval has a beginning, an end, and a duration, even if not known. Every time

 $\underline{\underline{interval}}$ is "finite", a bounded segment of the $\underline{\underline{Time\ Axis}}$. The beginning or end of a $\underline{\underline{time}}$ interval may be defined by reference to events that occur for a time interval that is not

Time intervals may be 'indefinite', meaning that their beginning is 'primordiality' or their Note:

end is 'perpetuity', or both ('eternity'). This vocabulary assumes that indefinite time

intervals exist and have some duration, but their duration is unknown.

an absolute time coordinate that refers to the time interval Reference Scheme:

Note: Absolute time coordinates are related to calendars, and are introduced in clause 10.6.

The lifetime of Henry V. Example:

The day whose Gregorian calendar date is September 11, 2001. Example:

8.2.1 The Whole-Part Relationship Among Time Intervals

The mereological principles described in Annex D.4 apply to time intervals.

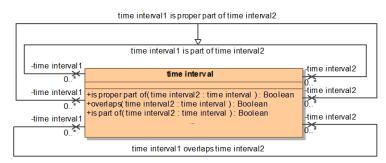

Figure 8.1 - Mereology as Applied to Time Intervals

time interval, is part of time interval,

Synonymous Form: time interval_1 includes time interval_1
Synonymous Form: time interval_1 is in time interval_2
Synonymous Form: time interval_1 in time interval_2

Definition: Time interval₂ is a component of time interval₁. Every instant in time interval₁ is also in time interval₂. Everything that happens in time interval₁ happens in time interval₂.

Note: Like the concept time interval itself, this relationship is also primitive – intuitive. It is a

mathematical ordering of time intervals by containment.

CLIF Axiom: (forall (t1 t2)

(if ("time interval1 is part of time interval2" t1 t2) (and ("time interval" t1) ("time interval" t2) ("thing1 is part of thing2" t1 t2))))

Note: The OCL operation signature implies this constraint.

Note: This relationship is based on the mereological verb concept 'part is part of whole' (Annex

D.4). All the axioms cited there for 'part is part of whole' apply to 'time interval is part

of time interval2'.

Note: The axioms of reflexivity, anti symmetry, and transitivity (Annex D.4) make 'time interval

is part of time intervals a partial ordering relationship on time intervals. The relationship is partial because two arbitrary time intervals might be disjoint or might overlap, so that

there is no part-whole relationship between them.

time interval, overlaps time interval,

Note:

CLIF Axiom:

(forall (t1 t2)

(if ("time interval1 overlaps time interval2" t1 t2)

(and ("time interval" t1) ("time interval" t2)

("thing1 overlaps thing2" t1 t2))))

time interval₁ is a proper part of time interval₂

Note: This relationship is based on the mereological verb concept 'part is a proper part of

whole' (Annex D.4). See the definition of that concept for details. For time intervals,

stronger supplementation axioms are given in 8.2.6.

CLIF Axiom: (forall (t1 t2)

(if ("time interval1 is proper part of time interval2" t1 t2)

(and ("time interval" t1) ("time interval" t2) ("thing1 is proper part of thing2" t1 t2))))

Note: The OCL operation signature implies this constraint.

Commented [EB4]: Issue 13-65 INSERT text

Commented [EB5]: Issue 13-67 REPLACE text

Deleted: <#>time interval overlaps time interval fine relationship is based on the mereological verb concept 'part_1 overlaps part_2' (Annex D.4). See the definition of that concept for details.

Note: A proper part is a part that is not the whole.

Axiom: There is no smallest time interval.

For each time interval, there is at least one time interval, that is a proper part of Necessity:

time interval₁.

CLIF Axiom: (forall (ti1 "time interval")

(exists (ti2 "time interval")

("proper part of" ti2 ti1)))
context__'time interval' OCL Constraint:

inv: self._'time interval1 is proper part of time interval2'::_'time interval1.\(\) notEmpty() This axiom requires the Open World Assumption: Things can exist without being explicitly Note:

included in a population.

8.2.2 The Temporal Ordering Relationship

A fundamental property of time intervals is the totally ordered 'is before' relationship, which defines temporal ordering.

time interval 1 is before time interval 2

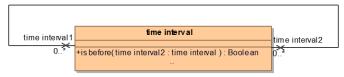

Figure 8.2 - Temporal Ordering

time interval, is before time interval,

Synonymous Form: time interval2 is after time interval1 Synonymous Form: time interval₁ < time interval₂ Synonymous Form: time interval₂ > time interval₁ Synonymous Form: time interval₁ precedes time interval₂ Synonymous Form: time interval₂ is preceded by time interval₁ Synonymous Form: time interval2 follows time interval1 Synonymous Form: time interval₁ is followed by time interval₂ Definition: time interval, ends before/when time interval, starts

In any given calendar, the <u>time interval</u> identified by <u>2010</u> is before the <u>time interval</u> Example:

identified by 2011.

Note: This relationship is also primitive – intuitive. It is a mathematical ordering of time

intervals by position on the Time Axis. Is before captures the intuition of the direction of time, of past and future: if x is before y, then y is in the future relative to x and x is in the

past relative to y. CLIF Axiom: (forall (t1 t2)

(if ("time interval1 is before time interval2" t1 t2)

(and ("time interval" t1) ("time interval" t2))))

The OCL operation signature implies this constraint. Note

The actual determination of the ordering of time intervals may be based on direct Note:

observation, on calendar knowledge, on historical knowledge, or on practical knowledge. One can see the order in which two vehicles enter an intersection and infer the

corresponding facts about the time intervals involved (observation). One can know from calendar rules that November 11, 1918 was before September 1, 1939. One can know from the reports of others (historical knowledge) that railroads were in use for many years before automobiles first appeared. Knowing that every airplane takes off before it lands (practical knowledge), and that a particular airplane has taken off and landed, one can infer that the

inv: _'time interval'.allInstances->

forAll(t2, t3 | self._'is before'(t2) and t2._'is before'(t3) implies self._'is before'(t3)) The preceding 3 axioms specify that 'time interval₁ is before time interval₂' is anti-reflexive, weakly antisymmetric, and transitive. The relationship does *not* apply to all pairs of time intervals. This characterizes a kind of partial ordering on time intervals.

8.2.3 The Allen Relations

In a 1983 paper [Allen], James F. Allen asserted that there are exactly thirteen ways in which an ordered pair of time intervals can be related. His Figure 2, showing these relationships, is reproduced below.

Relation	Symbol	Symbol for Inverse	Pictoral Example
X before Y	<	>	XXX YYY
X equal Y	=	-	XXX
X meets Y	m	mi	XXXYYY
X overlaps Y	0	oi	XXX
X during Y	d	di	XXX
X starts Y	S	si	XXX YYYYY
X finishes Y	f	fi	XXX

FIGURE 2. The Thirteen Possible Relationships

Figure 8.3 - Allen's Original Diagram of the 13 Time Relationships

According to Thomas Alspaugh [Alspaugh], these relations are *distinct* ("because no pair of definite intervals can be related by more than one of these relationships"), *exhaustive* ("because any pair of definite intervals are described by one of the relations"), and *qualitative*, rather than *quantitative*, ("because no numeric time spans are considered").

The word 'properly' is used in the terms for some of the Allen relations below, in order to distinguish those relations from the more general relations defined in 8.2.1 and 8.2.2. In each case of terminology clash, the Allen's term is narrower. The business use of the general term – before, after, part of, includes, during, overlaps – almost always means the more general relationship.

The Allen relations are *independent*: none is entailed by another and none is defined in terms of the others. They are, however, all defined here in terms of the two fundamental relationships: 'part of' and 'before'.

The 'properly before' and 'meets' relations are mutually exclusive. The primitive relationship 'before' subsumes both. Allen's 'before' concept is designated here as 'properly before' to indicate there is necessarily an intervening time interval.

The 'properly overlaps' relation distinguishes the case in which there is a part of each time interval that is not a part of the other from all the cases in which one time interval is entirely a part of the other. The general 'overlaps' relation subsumes all of them. 'Properly overlaps' describes the first time interval as starting earlier than the second starts and ending earlier than the second ends, whereas 'is properly overlapped by' describes the first time interval as starting later than the second starts, and ending later than the second ends.

The 'properly during,' 'starts', and 'finishes' relationships are mutually exclusive. The general 'part of' relationship subsumes all of them. They are distinguished by the temporal relationship of the included time interval to the supplementary parts of the whole.

8.2.5 Time Interval Sum

This sub clause describes the "sum" of two time intervals - the smallest time interval that contains both of them.

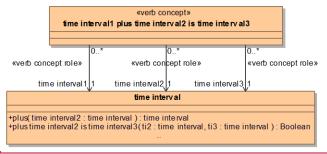

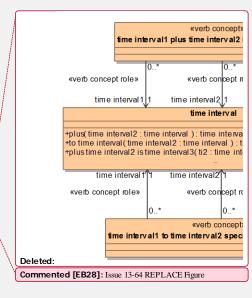

Figure 8.8 - Time Interval Sum

This concept of 'sum' is generalized. It may be said to represent the 'convex hull' of the two intervals, and it may contain intervals that lie between them. It is particularly useful, however, when t1 meets t2 or t2 meets t1, i.e., in those cases where t1 and t2 are disjoint and there is no time interval between them.

8.2.8 Time intervals defined by start and end

The above sections specify mathematical means of defining a time interval as the sum, complement, or intersection of two other time intervals. In practice, a time interval is more commonly defined by specifying when it starts and when it ends. This section introduces two verb concepts that support such a mechanism.

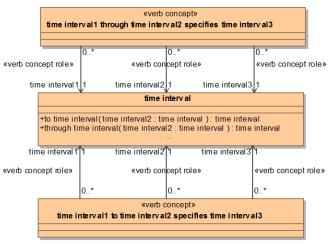

Figure 8.12 - Time intervals defined by start and end

time interval, through time interval, specifies time interval,

Synonymous Form:	time interval ₁ through time interval ₂ is time interval ₃	
Synonymous Form:	time interval ₃ is fromtime interval ₁ through time interval ₂	
Definition:	time interval ₁ starts before time interval ₂ , and	
	time interval ₁ starts time interval ₃ , and	
	time interval ₂ finishes time interval ₃	
CLIF Definition:	(forall (t1 t2 t3)

Note:	perpetuity is an individual concept. There can be only one time interval, that is after every
	other time interval.
Note:	This concept can be used in formulations such as "2012 through perpetuity" to define time
	intervals that extend indefinitely into the future. Tools may choose to support a convenient
	syntax such as "after 2012".
Example:	"Contract signing through perpetuity" meaning "after the contract signing".
Note:	perpetuity has a duration but it is not known.
Necessity:	perpetuity finishes eternity.
Note:	This follows from the definitions. No part of eternity can be after perpetuity.

8.3 Durations

A second foundational temporal concept is 'duration,' the amount of time in a time interval. This clause presents various properties of 'duration' and of the relationship between 'duration' and 'time interval'.

duration

Synonym: <u>time</u>

Definition: <u>base quantity</u> of the International System of Quantities, used for measuring <u>time intervals</u>

Note: <u>Duration</u> is a <u>quantity kind</u>, whose instances are <u>quantities</u> of time. Each <u>duration</u> is an

equivalence class of particular durations: a duration equals all the measurements for the

same amount of time.

Note: 'Duration' is a different concept from 'duration value'. 'Duration' is the amount of time in a

time interval. 'Duration value' is a quantification of 'duration' in terms of a time unit. There is a one-to-many relationship between <u>durations</u> and <u>duration values</u>. For example, the same <u>duration</u> may be quantified as any of the <u>duration values</u> "1 hour", or "60"

minutes", or "3600 seconds".

Reference Scheme: a precise atomic duration value that quantifies the duration

Source: [ISO/IEC 80000-3]

8.3.1 Duration Ordering

'Duration' has relationships, '=', ' \leq ', and '<' with the following properties. These relationships neither follow from nor entail the duration properties defined in the next clause. The four axioms defined in this section, taken together, define a total ordering on 'duration'.

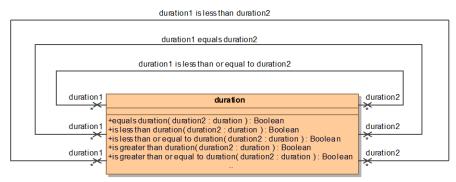

Figure 8.14 - Duration Ordering

duration is less than or equal to duration

Synonymous Form: $\frac{\text{duration}_1}{\text{duration}_2} \le \frac{\text{duration}_2}{\text{duration}_2} \ge \frac{\text{duration}_2}{\text{duration}_2}$

Synonymous Form: <u>duration</u>₂ is greater than or equal to <u>duration</u>₁

Definition: A total ordering on quantities of time.

Note: This is a primitive concept.

Example: Two runners start a race at the same time. The <u>duration</u> of the run of one runner is less than

or equal to the duration of the run of the other runner.

duration₁ equals duration₂

OCL Constraint:

Synonymous Form: $\underline{duration_1} = \underline{duration_2}$

Definition: $\underline{duration_1} \leq \underline{duration_2}$ and $\underline{duration_2} \leq \underline{duration_1}$

Example: Two runners start and complete a race at the same time. The duration of the run of one

runner is equal to the $\underline{\text{duration}}$ of the run of the other runner.

Axiom 0.1 (Reflexive): If d1 is a duration, then $d1 \le d1$. Necessity: Each duration \le the duration.

CLIF Axiom: (forall ((d1 duration))

("duration ≤ duration" d1 d1)

OCL Constraint: context duration

inv: self._'is less or equal'(self))

Axiom O.2 (Total): If d1 and d2 are durations, then either d1 \leq d2 or d2 \leq d1.

Necessity: Each $\underline{duration_1} \le \underline{each} \underline{duration_2} \underbrace{or} \underline{duration_2} \le \underline{duration_1}$.

CLIF Axiom: (forall ((d1 duration) (d2 duration))

(or

("duration ≤ duration", d1 d2) ("duration ≤ duration" d2 d1)))

context duration

inv: duration.allInstances->forAll(d2 |

self._'is less or equal(d2) or d2._'is less or equal'(self)

Axiom O.3 (Antisymmetric): If d1 and d2 are durations, and $d1 \le d2$ and $d2 \le d1$, then d1 = d2.

Necessity: If some $\underline{duration_1} \le \underline{some} \ \underline{duration_2}$ and the $\underline{duration_2} \le \underline{the} \ \underline{duration_1}$, then the

duration1 equals the duration2.

and not self.equals(d2)

8.3.2 Duration Operations

From a mathematical point of view, the extension of 'duration' is a vector space over the real numbers. That is, two operations – addition and scalar multiplication – are defined on durations. They operations obey the following axioms:

Axiom V.1 (Addition is Closed): If d1 and d2 are durations, then d1 + d2 is a duration.

Axiom V.2 (Addition is Associative): If d1, d2, d3 are <u>durations</u>, then (d1 + d2) + d3 = d1 + (d2 + d3).

Axiom V.3 (Addition is Commutative): If d1 and d2 are <u>durations</u>, then d1 + d2 = d2 + d1.

Axiom V.4 (Additive Identity): There is a <u>duration</u> D0 such that, for every <u>duration</u> d1, d1 + D0 = d1.

Axiom V.5 (Additive Inverse): For each <u>duration</u> d1, there is a <u>duration</u> d2, such that d1 + d2 = D0.

Note: The existence of the inverse (-d1) is a mathematical necessity for the vector space. Whether

it has physical meaning is quite another thing entirely.

Axiom V.6 (Scalar multiplication is closed): if d1 is a duration and n1 is a number, n1 * d1 is a duration.

Axiom V.7 (Scalar multiplication is distributive over <u>durations</u>): if d1 and d2 are <u>durations</u> and n1 is a real number, n1 * (d1 + d2) = (n1 * d) + (n1 * d2)

Axiom V.8 (Scalar multiplication is distributive over reals): if d1 is a <u>duration</u>, and n1 and n2 are <u>numbers</u> (n1 + n2) * d1 = n1 * d1 + n2 * d1.

Corollary: For all $\underline{durations} d1$, 0 * d1 = D0

Corollary: If n1 is a <u>number</u> and d1 is a <u>duration</u>, then n1 * d1 = D0 iff n1 = 0 or d1 = D0

Corollary (Ratio): If d1 and d2 are <u>durations</u> and not d2 = D0, then there exists a <u>number</u> n1 such that d2 = n1 * d1. We call n1 the "ratio of d2 to d1."

Note that the above does not depend on the concept 'time unit.' In fact, the usefulness of 'time unit' depends on this property.

Synonymous Form: duration<sub>3</sub> = duration<sub>1</sub> plus duration<sub>2</sub>
Synonymous Form: duration<sub>1</sub> plus duration<sub>2</sub> gives duration<sub>3</sub>
Synonymous Form: duration<sub>1</sub> + duration<sub>2</sub> gives duration<sub>3</sub>
```

Synonymous Form: duration₁ plus duration₂
Synonymous Form: duration₁ + duration₂

Note: This is a "ground concept" that cannot be defined in terms of other concepts.

Example: Some race consists of a run and a swim. For each racer, the <u>duration</u> of the race is the

<u>duration</u> of the run *plus* the <u>duration</u> of the swim.

Note: The following definition defines the CLIF duration addition function in terms of the verb

concept. The verb concept is primitive and has no formal definition.

CLIF Definition: (forall ((d1 duration) (d2 duration) d3)

(iff (= d3 (+ d1 d2))

(and (duration d3)

("duration3 = duration1 + duration2" d3 d1 d2))))

Axiom V.1 (Addition is closed): For all durations d1 and d2, there is a duration d3 such that d3 = d1 + d2.

Necessity: For each duration₁ and each duration₂ some duration₃ equals duration₁ plus duration₂.

Commented [EB42]: Issue 13-9 REPLACE text

CLIF Axiom: (forall ((d1 duration) (d2 duration))

(exists (d3 duration)

(= d3 (+ d1 d2))))

OCL Constraint: OCL Constraint: context duration

inv: duration->allInstances(forAll d2 |

self.plus(d2)) duration->allInstances(exists d3 | d3 =

Corollary: The sum of two durations is unique.

For each duration₁ and each duration₂ exactly one duration₃ equals duration₁ plus Necessity:

duration₂.

This follows from the transitivity of equality of durations in 8.3.1.

Axiom V.2 (Addition is Associative): If d1, d2, d3 are <u>durations</u>, then (d1 + d2) + d3 = d1 + (d2 + d3).

If a duration₄ equals a duration₁ plus a duration₂, and a duration₅ equals duration₄ Necessity:

plus duration3, and a duration6 equals duration2 plus duration3, then duration5

equals duration plus duration6

CLIF Axiom: (forall ((d1 duration) (d2 duration) (d3 duration))

(= (+ (+ d1 d2) d3) (+ d1 (+ d2 d3))))

OCL Constraint: context duration

inv: duration.allInstances->

forAll(d2, d3 |

(self._'plus duration'(d2) ._'plus duration'(d3))

.equals(self._'plus duration' (d2._'plus duration'(d3))))

Axiom V.3 (Addition is Commutative): If d1 and d2 are durations, then d1 + d2 = d2 + d1.

Necessity: Each duration₁ plus duration₂ equals duration₂ plus duration₁.

CLIF Axiom: (forall ((d1 duration))

(exists ((d2 duration))

(= (+ d2 d1) (+ d1 d2))))

OCL Constraint: context duration

inv: duration.allInstances->forAll(d2 | self._'plus duration'(d2).equals (d2._'plus duration'(self)))

Axiom V.4 (Additive Identity): There is a <u>duration</u> D0 such that, for every <u>duration</u> d1, d1 + D0 = d1.

zero duration Synonym: duration that is the additive identity whose existence is required by Axiom V.4. Definition:

Each duration plus D0 = the duration. Necessity:

CLIF Axiom: (and

(duration D0)

(forall (d duration) (= (+ d D0) d)))

context duration OCL Constraint:

inv: self = self. 'plus duration'(D0)

Declaring the individual concept (a logical "constant") asserts its existence. Note: Do is unique. The uniqueness of Do follows from the definition and the commutative axiom Note:

(V.3): If there is some other Dx such that d + Dx = d for all durations d, then D0 + Dx = D0,

but D0 + Dx = Dx + D0 and Dx + D0 = Dx, by definition of D0.

8.3.3 Relationships between 'Duration' and 'Time Interval'

The intent of the 'duration' concept is to measure time intervals, but the model presented above is a mathematical abstraction that does not depend on time intervals for its properties. What makes it useful is the following set of relationships between durations and time intervals.

Each time interval has a unique duration attribute that is a measure of its size, i.e., the amount of time the time interval occupies. This attribute is mathematically a function that maps time intervals into durations. This mapping function is sometimes called the "range" of a time interval, and sometimes called the "measure" of a time interval. Following SBVR practice, this specification calls it the duration of a time interval.

This sub clause describes the only special cases in which the <u>durations</u> of constructed <u>time intervals</u> are well-defined.

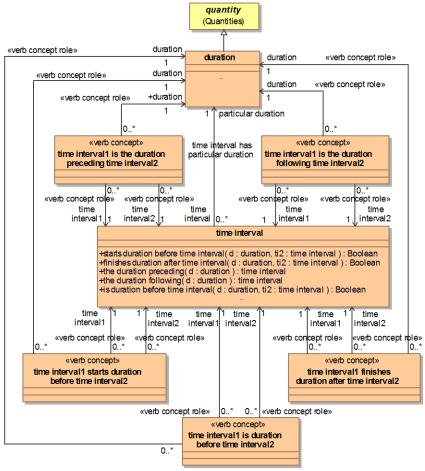

Figure 8.16 - Relationships between 'Duration' and 'Time Interval'

particular duration

Concept Type: role
General Concept: duration

Definition: the amount of time in a given time interval

Note: <u>particular duration</u> is an instance of <u>particular quantity</u> whose values are of the <u>quantity</u>

kind 'duration'.

Example: <u>Particular duration</u> of a particular meeting.

time interval has particular duration

Synonymous Form: <u>particular duration</u> of time interval

Synonymous Form: <u>time interval has duration</u>

Synonymous Form: duration of time interval

the particular duration is the duration that is the amount of time in the time interval Definition: Note:

This is a primitive concept. It is the fundamental relationship between time intervals and

durations. It has no formal definition. But there is a corresponding CLIF function, and a corresponding UML operation, and they can be formally defined in terms of the primitive

verb concept.

CLIF Definition: (forall (d ti) (iff

(= d ("duration of time interval" ti))

(and

("time interval" ti) (duration d) ("time interval has duration" ti d))))

The <u>duration</u> of Henry V's life is given by the <u>duration value</u> "35 years." Example:

CLIF Axiom:

(if ("time interval has duration" t d) (and ("time interval" t) (duration d))))

CLIF Definition: (forall (t d)

(iff (= ("duration of" t) d)

("time interval has duration" t d)))

Axiom D.1: Each time interval has exactly one duration.

Necessity: Each time interval has exactly one duration. (forall ((t "time interval") (d1 duration) (d2 duration)) CLIF Axiom:

(if (and ("time interval has duration" t d1)

("time interval has duration" t d2))

(= d1 d2)))

OCL Constraint: context _'time interval'

inv: self._'particular duration'->size() = 1

Axiom D.2: Every time interval has a positive duration.

Necessity: The duration of each time interval is greater than DO.

CLIF Axiom: (forall ((t "time interval"))

(> ("duration of" t) D0))

OCL Constraint: context _'time interval'

inv: self.duration > D0

Corollary: No time interval has duration DO

Necessity: The duration of no time interval equals Do.

CLIF Axiom: (forall ((t "time interval"))

(not (= ("duration of" t) D0)))

OCL Constraint: context _'time interval'

inv: not self.duration = D0

Corollary: No time interval has a duration that is the additive inverse of the duration of any time interval. Thus, the vector space 'duration' is larger than the image of the time intervals.

Necessity: For each time interval₁ there is no time interval₂ such that the duration of time

interval₁ plus the duration of time interval₂ equals <u>DO</u>.

CLIF Axiom: (not (exists ((t1 t2))

("duration3 = duration1 plus duration2"

D0 ("duration of time interval" t1) ("duration of time interval" t2))))

OCL Constraint: context _'time interval'

> inv: _'time interval'.allInstances->forAll(t2 | not ((self.duration() + t2.duration()) = D0))

Axiom D.3: If t1 and t2 are time intervals such that t1 is a part of t2, then $D(t1) \le D(t2)$.

Formatted: Axiom, Adjust space between Latin and Asian text, Adjust space between Asian text and numbers

```
Necessity:
                                 For each time interval<sub>1</sub> and each time interval<sub>2</sub> that is a part of time interval<sub>1</sub>, the
                                 duration of time interval<sub>2</sub> is less than or equal to the duration of time interval<sub>1</sub>.
    CLIF Axiom:
                                 (forall (t1 t2)
                                  (if ("time interval1 is part of time interval2" t1 t2)
                                     ("duration duration," ("duration of" t1) ("duration of" t2)) ))
    OCL Constraint:
                                 context 'time interval'
                                      inv: 'time interval'.allInstances->forAll(t2 |
                                       self._'is part of(t2)
                                     (implies self_'particular duration'._'is less than'(d2._'particular duration'))
Axiom D.4. If t1 and t2 are time intervals such that t1 meets t2, D(t1+t2) = D(t1) + D(t2).
                                 For each time interval, and each time interval, that meets a time interval, the
    Necessity:
                                 duration of time interval plus time interval is equal to the duration of time interval
                                 plus the duration of time interval.

8.4 Time Units

As with other <u>quantity kinds</u>, <u>durations</u> are measured in terms of units. Unlike other <u>quantity kinds</u>, common <u>time units</u> are not simple ratios of each other. This makes for considerable complexity in specifying these <u>time units</u>. The details of this complexity are deferred to Clause 10.

The fundamental source of the complexity is that one of the main time units, 'year,' is incommensurable with other time units, such as 'month' and 'day.' This fact is due to the derivation of "year" and "day" from physical characteristics of our world.

Commented [EB63]: Issue 13-9 INSERT text

8.4.1 Time Unit Concepts

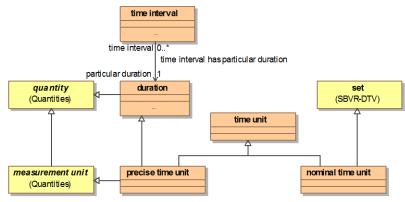

Figure 8.22 - Time Units

time unit

Definition: <u>precise time unit</u> or <u>nominal time unit</u>

Example: <u>year</u>, <u>week</u>, <u>hour</u>

precise time unit

Definition: measurement unit that is a duration

Note: [SI] defines 'hour', 'minute', and 'day' precisely. Although not addressed by [SI], 'week' also

meets the definition of 'precise time unit'. Leap seconds are considered to introduce

discontinuities in UTC, rather than variation in the definition of 'day'.

Example: <u>second</u>, <u>minute</u>, <u>hour</u>

nominal time unit

Definition: <u>set of durations</u> that is defined and adopted by convention, meaning <u>some duration</u> of

the <u>set</u>

Note: Sets of durations are quantified as 'duration value sets' in sub clause 8.7.

Note: Each nominal time unit can be traced to counting cycles of some natural phenor

Each <u>nominal time unit</u> can be traced to counting cycles of some natural phenomenon. Historically the phenomena have been astronomical: the orbital cycles of the Earth and the Moon and the diurnal cycle of the Earth. Unfortunately for time keeping, these cycles are incommensurable, requiring intercalary <u>time periods</u> to maintain synchronization. Leap days have been used since 46 BC with the introduction of the Julian calendar to keep the

calendar aligned with seasons of the year.

Note: 'Year' and 'month' are said to be 'nominal time units' because of the effects of leap days.

Example: Year defined as {365 days, 366 days}.

Example: Month defined as {28 days, 29 days, 30 days, 31 days}. Each month on the Gregorian calendar

is a choice of 28, 29, 30, or 31 days.

8.4.2 Standard Time Units

This sub clause provides standard concepts about times of day, as found in [ISO 8601] and [SI], and generally accepted around the world.

derived unit General Concept:

General Concept: precise time unit

Source:

Definition: the precise time unit that is quantified by '3600 seconds'

day

Synonym:

Definition:

the precise time unit that is quantified by 86400 seconds

'Day' is defined in [SI] as 86400 seconds. Leap seconds are intercalary seconds of day that are inserted as needed into UTC. Leap seconds do not affect the definition of 'day'. Note:

Note: The <u>duration</u> of a <u>calendar day</u> is not necessarily <u>1 day</u>, due to <u>leap seconds</u> and

discontinuities arising when a locality switches between standard time and daylight time. Note:

Different <u>calendars</u> may define "<u>day</u>" differently. Particularly, in <u>calendars</u> based on solar time rather than ephemeris time, the calendar day may be defined by sunrise to sunrise, sunset to sunset or noon to noon. In such cases, the <u>duration</u> of a <u>calendar day</u> varies cyclically through the calendar year by as much as half an hour, a phenomenon known as the Equation of Time. Solar time is measured by observations and instruments such as sun

dials, ephemeris time is measured by clocks.

year

Definition: the nominal time unit that is the duration of a time interval required for one revolution of

the Earth around the Sun, approximated to an integral number of days

Source: ISO 8601 (2.2.13, 'calendar year')

Definition: the nominal time unit that is quantified by {365 days, 366 days}

There are several methods for reckoning a year. The main method is the return of the Vernal Note:

Equinox. This is called a tropical year, whose length is 365.2424 days of 86 400 seconds. There are several other year schemes, whose length in days of 86 400 seconds varies from about 347 days to about 384 days, depending how a year is measured. Such schemes use the

term 'year' for different nominal units.

The definition of a year is dependent on the use of a specific calendar. See "Gregorian year." Note:

Note: The business term 'n years' commonly refers to the duration of a specific consecutive

sequence of 'year periods' (see 10.3).

month

Definition: the nominal time unit that is the duration of a time interval required for one rotation of the

Moon in its orbit around the Earth, approximated to a number of days.

ISO 8601 (2.2.12, 'month') Source:

the nominal time unit that is quantified by {28 days, 29 days, 30 days, 31 days} Definition: Note: The business term 'n months' commonly refers to the duration of a specific consecutive

sequence of 'month periods' (see 10.3).

Note: A lunar month is about 28 days, and is incommensurable with a year. Different calendars

define the number of days in a month differently. And the same calendar may define different calendar months to have different numbers of days. The Gregorian calendar has 12 calendar months that were rather arbitrarily set to a certain number of days by Roman

politicians, without synchronizing with the lunar cycle.

week

ISO 8601 (2.2.9, 'week') Source:

Definition:

the precise time unit that is quantified by 7 days
the precise time unit that is quantified by 604 800 seconds Definition:

8.5 **Time Scales**

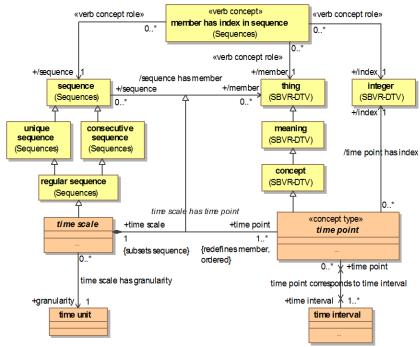

Figure 8.23 - Time Scales

time scale

Note:

regular sequence that each member of the regular sequence is a time point

Definition: Each time scale has exactly one granularity Necessity:

Necessity: If a member of a time scale has a previous member then each time interval that is

an <u>instance</u> of the <u>member</u> is met by some <u>time interval</u> that is an <u>instance</u> of the

previousmember.

Necessity: If a <u>member</u> of a <u>time scale</u> has a <u>next member</u> then each <u>time interval</u> that is an

instance of the member meets some time interval that is an instance of the next

member.

Note: These Necessities are really part of the definition of 'time scale'.

Dictionary Basis: IEC 60050-111. ("time scale") Dictionary Basis: IEC 8601, (2.1.4, "time scale")

Definition: system of ordered marks that can be associated with time intervals on the Time Axis, with

one time interval being chosen as the reference point

[from ISO 8601] A time scale may among others be chosen as:

continuous, e.g., international atomic time (TAI) (see IEC 60050-713, item 713-05-18);

continuous with discontinuities, e.g., Coordinated Universal Time (UTC) due to leap seconds, standard time due to summer time and winter time;

 successive steps, e.g., usual <u>calendars</u>, where the <u>Time Axis</u> is split up into a succession of consecutive <u>time intervals</u> and the same mark is attributed to all instants of each time interval;

discrete, e.g., in digital techniques.

Note: [from [SO 8601]] For physical and technical applications, a time scale with quantitative marks is preferred, based on a chosen initial instant together with a unit of measurement.

[from [SO 8601] Customary time scales use various units of measurement in

combination, such as <u>second</u>, <u>minute</u>, <u>hour</u>, or various <u>time intervals</u> of the <u>calendar</u> such as

combination, such as <u>second, fillule, flour,</u> or various <u>time intervals</u> of the <u>catendar</u> such calendar day, <u>calendar month</u> and <u>calendar year</u>.

Note: [from | SO 8601] A time scale has a reference point which attributes one of the marks of the

time scale to one of the instants, thus determining the attribution of marks to instants for

the Time Scale.

Note: Each semantic community should agree on a closed set of time scales.

Example: The clock face of a traditional clock is a <u>time scale</u>.

granularity

Note:

Synonym: resolution
Concept Type: role
General Concept: time unit

Dictionary Basis: VIM (4.15, 'resolution (2)')

Definition: the smallest <u>duration</u> that can be distinguished with a given <u>time scale</u>

Necessity: Each time scale has exactly one granularity

Example: "Second" as the granularity for a time scale in which each time point has the duration "1

second."

time scale has granularity

Definition: The granularity of the time scale is the duration of the time points of the time

<u>scale</u>.

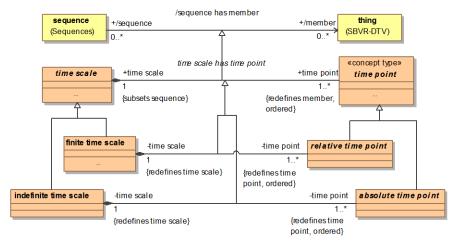

Figure 8.24 - Time Scale Kinds

finite time scale

Definition: <u>time scale</u> that has a <u>first member</u> and that has a <u>last member</u>

Note: A <u>finite time scale</u> has a <u>cardinality</u>.

Necessity: Each time point of a finite time scale is a relative time point

Example: the <u>Gregorian year of months scale</u>
Example: the <u>hour of minutes scale</u>

indefinite time scale

Definition: <u>time scale</u> that is not a <u>finite time scale</u>

Necessity: Each time point of an indefinite time scale is an absolute time point.

Note: An indefinite time scale has no cardinality because it has no first member, no last

member, or both.

Example: the Gregorian years scale

absolute time point

Definition: <u>time point that is of an indefinite time scale</u>

Necessity: Each absolute time point corresponds to exactly one time interval.

Example: The absolute time coordinate 'September 11, 2011' indicates an absolute time point.

relative time point

Definition: <u>time point</u> that is of a finite time scale

Necessity: Each relative time point corresponds to more than one time interval.

Example: The <u>relative time coordinate</u> 'September 11' refers to multiple <u>time intervals</u>, one in each

<u>Gregorian year</u>.

8.6 Time Points

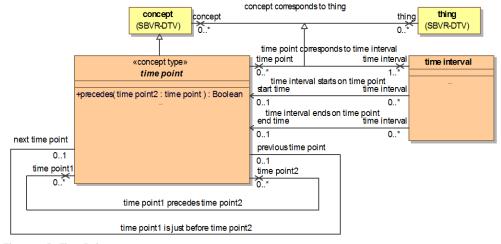

Figure 8.25 - Time Points

time point

Concept Type: concept type General Concept: time period

Definition: concept that specializes the concept 'time interval' and that is a member of a time

scale

Necessity: The duration of each time interval that is an instance of the time point is the

granularity of the time scale of the time point.

Note: Each time point is a concept whose instances are time intervals.

Reference Scheme: an occurrence at the time point

Reference Scheme: a time coordinate that indicates the time point Reference Scheme:

the time scale of the time point and the index of the time point Reference Scheme: the time point kind of the time point and the index of the time point

This is a total reference scheme: every time point is indicated by at least one time Note:

coordinate, and some time points may be indicated by multiple time coordinates.

The Battle of Hastings was on "14 October 1066". (This gives the Julian date of the battle

at a granularity of "day". If desired, the battle could be given more precisely as a time

period within that calendar day.)

time scale has time point

Example:

Synonymous Form: time point is on time scale General Concept: sequence has member

Necessity: Each time scale has at least one time point. Each time point is of exactly one time scale. Necessity:

time point has index

Definition: the index is the index of the sequence position that is in the time scale of the time

point and that has a member that is the time point

Necessity: Each time point has exactly one index.

time point, precedes time point,

Synonymous Form: time point₂ follows time point₁

Definition: the time scale of time point, is the time scale of time point, and the index of time

point_is less than the index of time point2

Note: This is a special case of member precedes member in the unique sequence that is the

time scale of the two time points

time point, is just before time point,

Synonymous Form: time point2 is next after time point1

Definition: the time scale of time point, is the time scale of time point, and the sequence

position of time point, is just before the sequence position of time point, in the time

scale of time point1

time interval starts on time point

Synonymous Form: time point starts time interval

Definition: some time interval that is an instance of the time point starts the time interval

time interval ends on time point

Synonymous Form: <u>time point</u> ends time interval

Definition: me <u>time interval</u> that *is* an <u>instance</u> of the <u>time point</u> finishes the <u>time interval</u> Commented [EB64]: Issue 13-2 REFORMAT text

8.7 Time Periods and Time Point Sequences

This sub clause introduces a general mechanism for references to time intervals.

Many references to time intervals involve expressions using time points to denote the ends of the time interval, such as "2 p.m. to 4 p.m." Formally, such time intervals may be said to instantiate consecutive sequences of time points on some time scale, what is here called a time point sequence. A single time point used to refer to a time interval may be regarded as a special case of a time point sequence. And like a time point, a time point sequence can refer to more than one time interval, e.g., "2 p.m. to 4 p.m. on Mondays."

The time intervals that are specified in this way are common in business, and are considered a special class of time interval, called <u>time period</u>. The business user understands the names for the time points and the time period concept; the user need not be aware of the formal model.

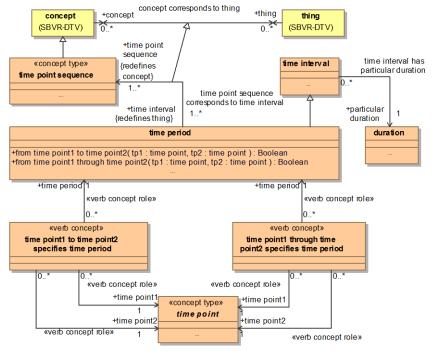

Figure 8.26 - Time periods and time point sequences

time point sequence

Concept Type: concept type

Definition: consecutive sequence of time points

Necessity: All the <u>time points of a given time point sequence</u> are on the same <u>time scale</u>.

Note: This is formalized by the Definition and Necessity under 'time point sequence is on time

scale'.

Note: A <u>time point sequence</u> is not necessarily a subsequence of a <u>time scale</u> because a <u>time</u>

<u>point sequence</u> may "wrap around" a <u>finite time scale</u> by including <u>time points</u> from the end of the <u>time scale</u>, followed by <u>time points</u> from the start of the <u>time scale</u>.

Reference Scheme: The first time point of the time point sequence and the last time point of the time

point sequence.

Reference Scheme: The first time point of the time point sequence and the duration of the time point

sequence.

Reference Scheme: The last time point of the time point sequence and the duration of the time point

sequence.

 Necessity:
 Each time point sequence has at least one member.

 Necessity:
 Each time point sequence has exactly one first time point.

 Necessity:
 Each time point sequence has exactly one last time point.

Note: It is not possible to specify an indefinite time point sequence; i.e. one that has no first

time point or no last time point. A time point sequence is a specific section of a calendar. It is possible to specify a time point sequence by specifying the first time point or last time point to be the date or time of an event, including primordiality and perpetuity, if appropriate. It is also possible to specify a time interval by means other than a time point

sequence (see clause 16.7).

Necessity: The first time point of each time point sequence that is on an indefinite time scale

and that has more than one member precedes the last time point of the time point

sequence.

Note: In a time point sequence on an <u>indefinite time scale</u>, the time points are consecutive. But a

time point sequence can "wrap around" the end of a finite time scale. For example, "December 25 through January 4". The definition of 'time point sequence corresponds to time interval' just requires the start and finish of the time interval to instantiate the first and last time point. The relationship of the time point sequence to the time scale follows from

that requirement.

Example: 22:00 to 06:00

Example: The <u>time point sequence</u> from July 1, 2009 to August 3, 2010.

time point sequence corresponds to time interval

Synonymous Form: <u>time interval</u> instantiates <u>time point sequence</u>

Definition: the time interval starts on the first time point of the time point sequence and the

duration of the time interval is the duration of the time point sequence

Necessity: Each time point sequence that is on an indefinite time scale corresponds to exactly

one time interval.

Note: The corresponding time intervals are determined by the first time point and the cardinality

of the time point sequence. This is correct even when the time point sequence "wraps

around" the end of a finite time scale.

time point sequence has duration

Definition: the duration equals the cardinality of the time point sequence times the granularity

of the time point sequence

Necessity: Each time point sequence that has a first time point and a last time point has exactly

one duration.

Necessity: Each time point sequence that has no first time point or no last time point has no

duration.

Note: The duration of such a time sequence is infinite.

Example: The duration of the time point sequence consisting of Monday, Tuesday, and

Wednesday is 3 days.

time period

Definition: <u>time interval that instantiates some time point sequence</u>

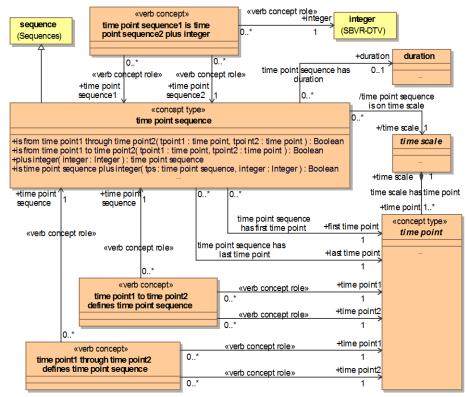

Figure 8.27 - Time point sequence structure

time point sequence is on time scale

Synonymous Form: <u>time scale</u> of time point sequence

Definition: each time point of the time point sequence is a member of the time scale

Necessity: Each time point sequence is on exactly one time scale.

Example: A time point sequence consisting of seconds of day is on the day of seconds scale.

time point sequence₂ is time point sequence₁ plus integer

Synonymous Form: <u>time point sequence_2</u> = <u>time point sequence_1</u> + <u>integer</u>

Synonymous Form: time point sequence₁ plus integer
Synonymous Form: time point sequence₁ + integer

Definition: <u>time point sequence</u> is on the <u>time scale</u> of <u>time point sequence</u> and the <u>index</u>

origin position of time point sequence2 is the index origin position of time point

sequence₁+ the integer

Description: The <u>time point sequence</u>₁ is shifted by the <u>integer</u>.

Necessity: If a <u>time point sequence_1</u> is a <u>time point sequence_2</u> plus an <u>integer</u>, then <u>time point</u>

sequence₁ is on an indefinite time scale and time point sequence₂ is on the

indefinite time scale.

Example: The time point sequence 2 July 2012 through 4 July 2012 is the time point sequence 1

July 2012 through 3 July 2012 plus 1.

first time point

Synonym: start time point

Concept Type: role
General Concept: time point

time point sequence has first time point

Synonymous Form: <u>first time point of time point sequence</u>

Definition: the first time point is the first member of the time point sequence

Example: The time coordinate of the first time point of the time point sequence from July 1, 2009

to <u>August 3, 2010</u> is <u>July 1, 2009</u>.

last time point

Synonym: end time point

Concept Type: role
General Concept: time point

time point sequence has last time point

Synonymous Form: <u>last time point of time point sequence</u>

Definition: the <u>last time point</u> is the <u>last member</u> of the <u>time point sequence</u>

Example: The <u>time coordinate</u> of the <u>last time point</u> of the <u>time point sequence</u> from July 1, 2009

to August 3, 2010 is August 3, 2010.

time point, through time point, defines time point sequence

Synonymous Form: <u>time point sequence is from time point</u> through time point2

Definition: time point₁ is the first time point of the time point sequence and time point₂ is the last

time point of the time point sequence

time point₁ to time point₂ defines time point sequence

Synonymous Form: <u>time point sequence is from time point</u> to time point

Definition: time point₁ is the first time point of the time point sequence, and if time point₂ is the

first member of the time scale of the time point sequence, the last time point of the

time point sequence is the last member of the time scale,

and if time point₂ is not the first member of the time scale, the last time point of the time point sequence is the time point that is just before time point₂ (on the time scale)

time point through time point specifies time period

Synonymous Form: time point through time point

Definition: the time point sequence that is from time point through time point corresponds to

the time period

Possibility: If the time scale of time point is a finite time scale then time point through time

point₂ specifies more than one time period.

Note: Contrast 'through' with 'to.' 'Through' is inclusive of time point, while 'to' is exclusive

of time point2.

Example: "January through March", meaning the time interval of 3 months duration that starts with

January and ends with March.

time point, to time point, specifies time period

Synonymous Form: <u>time point_1</u> to time point_2

Definition: the time point sequence that is from time point to time point corresponds to the

time period

Possibility: If the time scale of time point, is a finite time scale then time point, through time

point₂ specifies more than one time period.

Note: Contrast 'through' with 'to.' 'Through' is inclusive of time point, while 'to' is exclusive

of time point2.

Example: "January to March", meaning the time interval of 2 months duration that starts with January

and ends with February.

9 Duration Values (normative)

9.1 General

A <u>duration value</u> is a conceptual structure of meaning that serves to identify a <u>duration</u>. <u>Duration values</u> are amounts of time stated in terms of one or more <u>time units</u>. For example, "<u>60 seconds</u>" or "<u>1 minute</u>". The concept '<u>duration value</u>', and related concepts, specialize '<u>quantity value</u>' (Annex D.2.3) and its related concepts. These concepts are restated here for clarification and to bring them into this normative text.

In this specification, a <u>precise duration value</u> <u>quantifies</u> a <u>duration</u>. The key difference between '<u>duration value</u>' and '<u>duration</u>' is that a single <u>duration</u> may be quantified by multiple <u>precise duration values</u>. For example, "<u>60 seconds</u>" and "1 minute" quantify the same duration: the two duration values are <u>equivalent</u>.

Complexity arises with <u>duration values</u> that use the <u>nominal time units 'month</u>' and '<u>year</u>' because the number of <u>calendar days</u> varies among <u>calendar months</u>, and because some <u>calendar years</u> incorporate <u>leap days</u>. For example, "<u>1 year</u>" is equivalent to "<u>12 months</u>" but it is unclear in everyday usage how "<u>12 months</u>" compares to "<u>365 days</u>". To help answer the question, this clause introduces the concept of '<u>duration value set</u>'. A <u>duration value set</u> specifies a <u>set</u> of <u>duration values</u> that are jointly considered equivalent to a <u>nominal duration value</u>. For example, "<u>1 month</u>" is any of {<u>28 days</u>, <u>29 days</u>, <u>30 days</u>, <u>31 days</u>}.

Furthermore, this clause specifies common arithmetic and comparison operations on <u>nominal duration values</u> defined as <u>duration value sets</u>. This helps to define what expressions such as "<u>3 months</u>" or "<u>3 months</u>" plus <u>3 days</u>" mean. The advantage of this approach is that it clarifies the results of comparisons such as "<u>3 months</u> > <u>90 days</u>."

Duration Values Vocabulary

General Concept: terminological dictionary

Language: English

Included Vocabulary: <u>Time Infrastructure Vocabulary</u>

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#DurationValuesVocabulary

Deleted: 20150301

9.2 Duration Values

duration value

 Definition:
 precise duration value or nominal duration value

 Definition:
 atomic duration value or compound duration value

Necessity: Each duration value has at least one atomic duration value.

Note: A <u>duration value</u> can be either <u>atomic</u> or <u>compound</u> and either <u>nominal</u> or <u>precise</u> (see sub

clause 9.3).

Example: 45 seconds, 1 year 3 days

9.2.1 Atomic and Compound Duration Values

<u>Duration values</u> can be either atomic (have just one component, such as <u>10 minutes</u>) or be compound (a combination of multiple <u>atomic duration values</u>, such as <u>1 year 5 months</u>). <u>Atomic duration values</u> consist of a <u>number</u> and a <u>time unit</u>, such as "<u>4 weeks</u>." <u>Compound duration values</u> comprise multiple <u>atomic duration values</u>. For example, "<u>3 years 5 months</u>".

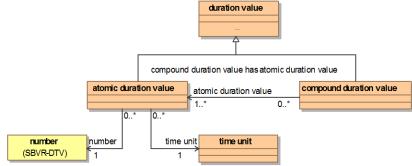

Figure 9.1 - Duration Values

atomic duration value

Definition: <u>number</u> and <u>time unit</u> together giving magnitude of a <u>duration</u>

Dictionary Basis: VIM 1.19 'quantity value'

Example: <u>55 seconds</u> is an <u>atomic duration value</u>

atomic duration value has number

Definition: if the atomic duration value is a precise atomic duration value, then the number is

the ratio of the <u>duration</u> *quantified by* the <u>atomic duration value</u> to the <u>time unit</u> of the

atomic duration value

Definition: if the atomic duration value is a nominal atomic duration value, then the number is

the ratio of exactly one of the elements of the duration value set that is specified by

the <u>atomic duration value</u> to the <u>time unit</u> of the <u>atomic duration value</u>

Note: In the general case, the <u>number</u> is a mathematical real or complex number. Because the

<u>number</u> is a ratio, rational fractions are commonly used in stating <u>duration values</u>. Thus, it is meaningful to say a task took <u>2.5 days</u> to complete. Fractional <u>numbers</u> are not defined for <u>nominal atomic duration values</u> (except for <u>½ year</u>, <u>¼ year</u>, and <u>¾ year</u>), because they

have no clear meaning.

Example: <u>2.5 years</u>, <u>5.6318 seconds</u>

Deleted:

Note: When the number is a non-negative integer, it may be thought of as a count of the time

units in the duration value. But that view only applies to certain measurement techniques,

such as the count of ticks of a clock.

Example: 8 months

Possibility: The <u>number</u> is less than <u>0</u>.

Note: Although there are no negative <u>durations</u>, the <u>number</u> of an <u>atomic duration value</u> may

be negative. A <u>duration value</u> may <u>quantify</u> a (positive) <u>duration</u> even though a component <u>atomic duration value</u> is negative. Typically, a negative <u>atomic duration</u>

Note: value arises as an intermediate result of a subtraction.

Note: "1 hour 12 minutes - 14 minutes equals 1 hour - 2 minutes", which quantifies the same

duration that is quantified by "58 minutes".

atomic duration value has time unit

Definition: if the atomic duration value is a precise atomic duration value, then the time unit is

the reference <u>duration</u> to which the ratio of the <u>duration</u> quantified by the <u>atomic</u>

duration value is taken

Definition: if the atomic duration value is a nominal atomic duration value, then the time unit is

the reference duration to which the ratio of exactly one element of the duration value

set specified by the atomic duration value is taken

Example: "45 minutes" has the time unit 'minute'

compound duration value

Definition: combination of two or more <u>atomic duration values</u> that have different <u>time units</u>

Example: "<u>2 hours 20 minutes</u>" quantifies the <u>duration</u> that may also be quantified as "<u>140 minutes</u>"

duration value has atomic duration value

Definition: the <u>atomic duration value</u> is one of the summands of the <u>duration value</u>

Example: 1 hour 5 minutes 3 seconds is a compound duration value that is composed of three atomic

duration values: 1 hour, 5 minutes, 3 seconds

9.2.2 Precise Duration Values

<u>Time units</u> are either precise (such as <u>seconds</u>) or nominal (that is <u>years</u>, which can be either $\underline{365}$ <u>days</u> or $\underline{366}$ <u>days</u>; and \underline{months} , which can be $\underline{28}$ <u>days</u>, $\underline{29}$ <u>days</u>, $\underline{30}$ <u>days</u>, or $\underline{31}$ <u>days</u>). <u>Duration values</u> are also nominal or precise according to whether they use nominal or precise \underline{time} <u>units</u>.

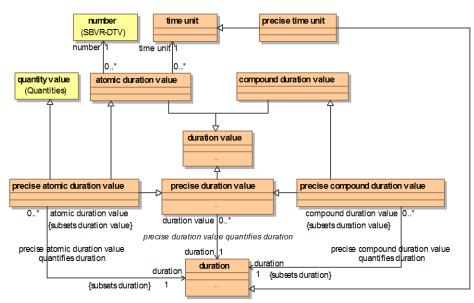

Figure 9.2 - Precise Duration Values

precise duration value

precise atomic duration value or precise compound duration value Definition:

Example: 5 hours Example: 3 days 5 hours

precise atomic duration value

Definition: quantity value that is an atomic duration value that has a precise time unit Note:

The <u>duration</u> quantified by a <u>precise</u> atomic duration value is the <u>duration</u> whose ratio

to the time unit is the number.

30 seconds Example:

precise compound duration value

Definition: compound duration value that is the combination of two or more

precise atomic duration values that have different time units

Example: 5 minutes 30 seconds

Each precise time unit (i.e., the time units 'second,' 'minute,' 'hour,' 'day,' and 'week') is defined as quantifying a multiple of 'second' using the pattern 'the precise time unit that quantifies < some number of seconds'. Thus, every precise atomic duration value (i.e., an atomic duration value that uses one of those time units) quantifies a duration that is some multiple of 'seconds'. For example, '3 hours' quantifies a duration of 10 800 seconds.

precise atomic duration value quantifies duration

duration is quantified by precise atomic duration value Synonymous Form:

Definition: the ratio of the duration to the time unit of the precise atomic duration value is the

number of the precise atomic duration value

Example: "2 seconds" quantifies a duration that is twice the duration of the time unit 'second'

Example: "1 minute 3 seconds" quantifies a duration that is 63 times the duration of the time unit

'second'

<u>Precise compound duration values quantify durations</u> via a computation that can be summarized as "quantify all the <u>atomic duration values</u> of the <u>precise compound duration value</u> as <u>durations</u>, and then sum them". For example, <u>a hours 30 minutes 20 seconds</u> quantifies a <u>duration</u> of '<u>9 0 20 seconds</u>'.

precise compound duration value quantifies duration

Synonymous Form: <u>duration</u> is quantified by <u>precise compound duration value</u>

Definition: the duration is the sum of the durations that are quantified by each precise atomic

duration value of the precise compound duration value 12 weeks 3 days quantifies the duration '8 380 800 seconds'

9.2.3 Nominal Duration Values

Example:

Nominal duration values are distinguished from precise nominal duration values because a <u>nominal duration value</u> is one of several <u>durations</u> as defined by a calendar. For example, the <u>compound nominal duration value</u> "<u>1 year 1 day</u>" is any of <u>{366 days</u>, <u>367 days</u>} because <u>1 year plus 1 day</u> could be either of those.

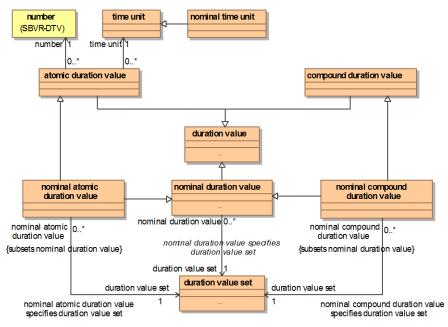

Figure 9.3 - Nominal Duration Values

nominal duration value

Definition: nominal atomic duration value or nominal compound duration value

Necessity: The <u>nominal duration value</u> is the <u>range</u> of a <u>time interval</u> identified by a <u>time period</u>

of a time calendar.

Example: <u>5 months</u>, for example from <u>February</u> through <u>June</u>
Example: <u>2 years 6 months</u>, for example from <u>January 1990</u>

nominal atomic duration value

General Concept: <u>atomic duration value</u>

Definition: <u>number</u> and <u>nominal time unit</u> together that specify a <u>duration value set</u>
Note: See sub clauses 9.3 and 9.4 for the detailed definition of this concept.

Example: <u>30 months</u>

nominal compound duration value

Definition: compound duration value that has at least one atomic duration value that is a

nominal atomic duration value

Possibility: An atomic duration value of the nominal compound duration value is a precise

atomic duration value.

Example: 1 year 1 day

Each <u>nominal time unit</u> (i.e., the <u>time units</u> '<u>year</u>' and '<u>month'</u>) is defined as *specifying* two or more choices among different numbers of '<u>days</u>' using the pattern 'the <u>nominal time unit that specifies</u> {<number1> <u>days</u>, <number2> <u>days</u>, ..., <numbern> <u>days</u>}'. This captures the idea that a <u>year</u> is either <u>365 days</u> or <u>366 days</u>, and a <u>month</u> is anywhere from <u>28</u> to 31 days.

nominal atomic duration value specifies duration value set

Synonymous Form: <u>duration value set</u> is specified by <u>nominal atomic duration value</u>

Definition: the <u>duration value set</u> is a function of the <u>nominal time unit</u> of the <u>nominal atomic</u>

duration value and the number of the nominal atomic duration value, and that function

depends upon the nominal time unit

Note: The meaning of this verb concept is further defined in specializations, two which are

defined in clauses 11.5 and 11.6: 'year value specifies duration value set' and 'month value specifies duration value set'. Other vocabularies can add their own for other

nominal time units

Example: 2 years specifies {730 days, 731 days} because the nominal time unit 'year' specifies the

duration value set {365 days, 366 days} and there are no two consecutive leap years

Unlike <u>precise atomic duration values</u>, a <u>nominal atomic duration value</u> is not a simple multiple of the <u>duration values</u> of the <u>duration value set</u> specified by the <u>nominal time unit</u> of the <u>nominal atomic duration value</u>. For example, <u>2 years</u> does not <u>quantify</u> "2 * <u>366 days</u>" because, in the Gregorian calendar, two successive years cannot both be leap years. Thus,

2 years specifies one of {365 + 365 days, 365 + 366 days}. Sub clauses 11.5 and 11.6 formally define this for the 'year' and 'month' nominal time units.

A nominal compound duration value comprises two or more nominal atomic duration values. Each of these nominal atomic duration values specifies a duration value set, as described above. The entire nominal compound duration value specifies a duration value set that is the summation of the individual duration value sets. The summation is computed by pairwise addition of each of the duration values sets that are quantified by the nominal atomic duration values. Adding two duration value sets is defined by the verb concept 'duration set_3 = duration set_1 + duration set_2' in sub clause 9.5.

nominal compound duration value specifies duration value set

Synonymous Form: <u>duration value set</u> is specified by <u>nominal compound duration value</u>

Definition: the <u>duration value set</u> is the sum of the <u>duration value sets</u> that are specified by

each atomic duration value of the nominal compound duration value

Example: 14 months 3 days specifies the duration value set 427 days, 428 days, 429 days, 430 days,

431 days}

9.3 Duration Value Arithmetic

Addition and subtraction of <u>duration values</u>, and multiplication and division of <u>duration values</u> by scalar <u>numbers</u>, is defined in terms of the corresponding operations on the individual components of the <u>duration values</u>. For example, "1 year5 months + 8 months 8 days" produces "<a href="1 year13 months 8 days"/1 year13 months 8 days". This avoids the complexities of mixed-base arithmetic, which are not resolvable in the case of nominal duration values. (As an example of those complexities, consider that "<a href="14 days"/14 days"/14 days"/14 days"/14 might be equivalent to either "<a href="28 days"/28 days"/28 days"/28 days" or "<a href="1 month"/1 month" depending upon the particular month.)

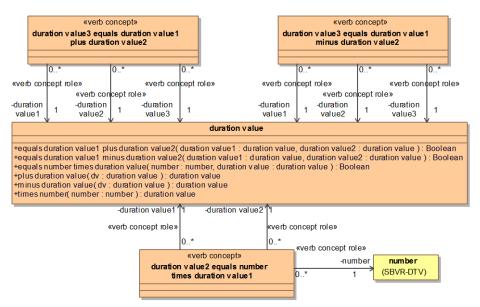

Figure 9.4 - Duration Value Arithmetic

duration value₃ equals duration value₁ plus duration value₂

Synonymous Form: <u>duration value_1 plus duration value_2</u>

Synonymous Form: $\underline{duration\ value_3} = \underline{duration\ value_1} + \underline{duration\ value_2}$

Synonymous Form: <u>duration value_1 + duration value_2</u>

Definition: each atomic duration value₃ of duration value₃ equals the sum of the <u>number₁ of an</u>

atomic duration value₁ of duration value₁ and either the number₂ of some atomic duration value₂ of duration value₂ that has the same time unit, or 0 if there does not exist an atomic duration value₂ of duration value₂ that has the same time unit

Note: This does not use "carries" among atomic duration values of different time units,

because they don't work for nominal time units. The numbers of the atomic duration

values that comprise duration value₃ may be greater than defined in the

corresponding time unit.

Example: <u>6 years 367 days 4 hours 61 minutes</u> *equals* <u>5 years 3 days 4 hours 3 minutes</u> *plus* <u>1 year 364</u>

days 58 minutes

Note: Tools may represent the results of <u>duration value</u> addition using mixed-base "carries"

when practical.

Example: 1 hour 80 minutes equals 1 hour 35 minutes plus 45 minutes. A tool may choose to display this

result as 2 hours 20 minutes.

duration value₃ equals duration value₁ minus duration value₂

Synonymous Form: <u>duration value_1 minus duration value_2</u>

Synonymous Form: <u>duration value_3 = duration value_1 - duration value_2</u>

Synonymous Form: <u>duration value_1 - duration value_2</u>

Definition: each atomic duration value₃ of duration value₃ equals the number₁ of an atomic

duration value₁ of duration value₁ minus either the number₂ of some atomic duration value₂ of duration value₂ that has the same time unit, or 0 if there does not exist an

atomic duration value₂ of duration value₂ that has the same time unit

Possibility: The number of some atomic duration value of duration value, may be negative.

Note: This does not use "borrows" among atomic duration values of different time units, because they don't work for nominal time units. Negative atomic duration values may occur.

Example: <u>1 year -5 days</u> equals <u>1 year 45 days</u> minus <u>50 days</u>

duration value₂ equals number times duration value₄

Synonymous Form: <u>duration value equals duration value times number</u>

Synonymous Form: number times duration value Synonymous Form: duration value times number

Synonymous Form: $\frac{\text{duration value}}{\text{duration value}} = \frac{\text{number}}{\text{duration value}} * \frac{\text{duration value}}{\text{duration value}} = \frac{\text{number}}{\text{duration value}} * \frac{\text{number}}{\text{duration value}} = \frac{\text{number}}{\text{duration value}} * \frac{\text{n$

Synonymous Form: number *duration value Synonymous Form: duration value *number duration value *number

Definition: each atomic duration value₁ of duration value₁ multiplied by the given number equals

some atomic duration value₂ of duration value₂

Example: <u>5 days quantifies the duration that equals 5 times 1 day</u>

Possibility: The <u>number</u> is negative.

Example: <u>-5 days</u>

Note: Negative <u>duration values</u> arise from arithmetic formulae. However, a negative

duration value does not quantify any duration.

Possibility: If <u>duration value_1</u> is a <u>precise duration value</u> then the <u>number</u> is fractional.

Example: <u>5.5 days quantifies the duration that equals 5.5 times 1 day</u>

 Necessity:
 3 months equals ½ times 'year.'

 Necessity:
 6 months equals ½ times 'year.'

 Necessity:
 6 months equals ½ times 'year.'

 Necessity:
 9 months equals ¾ times 'year.'

Note: This specification defines only the fractional <u>nominal duration values ¼ year</u>, ½ year, 24

year, and <u>4 year</u> because these are in common business use and they equal an integral

number of months.

Example: 5.5 years quantifies the duration that equals 5.5 times 1 year

9.4 Duration Value Comparison

Comparison of <u>duration values</u> is defined in terms of the same operations on the <u>quantified durations</u> or <u>specified duration values</u> is that these comparisons have useful results for many <u>nominal duration values</u>. For example, the expression "<u>1 year 1 day</u> > <u>365 days</u>" is <u>true</u> for both possible <u>duration values</u> that are <u>specified by 1 year 1 day</u>.

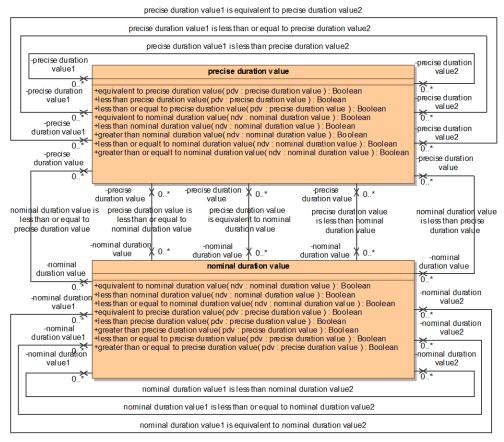

Figure 9.5 - Duration Value Comparison

precise duration value is equivalent to precise duration value

Synonymous Form: precise duration value₁ equals precise duration value₂
Synonymous Form: precise duration value₁ = precise duration value₂

Definition: <u>precise duration value_1 quantifies duration_1 and precise duration value_2 quantifies</u>

 $\underline{duration_2}$ and $\underline{duration_1} = \underline{duration_2}$

Example: "3 days 12 hours" is equivalent to "84 hours"

nominal duration value is equivalent to nominal duration value

Synonymous Form:

Synonymous Form:

Definition:

nominal duration value
nominal duration value
nominal duration value
duration value
duration value
nominal dura

and nominal duration value₂ = duration value set₂ and duration value set₁ = duration value set₂ Example: "1 month" is equivalent to "1 month"

Example: "1 year 1 day" is not equivalent to "366 days"

precise duration value is equivalent to nominal duration value

Synonymous Form: <u>precise duration value equals nominal duration value</u>
Synonymous Form: <u>precise duration value = nominal duration value</u>

Synonymous Form: nominal duration value is equivalent to precise duration value

Synonymous Form: nominal duration value equals precise duration value
synonymous Form: nominal duration value = precise duration value

Definition: nominal duration value quantifies a duration value set and precise duration value

quantifies a duration that = some duration of the duration value set

Example: "28 days" is equivalent to "1 month"

precise duration value₁ is less than or equal to precise duration value₂

Synonymous Form: precise duration value2 is greater than or equal to precise duration value1

Synonymous Form: <u>precise duration value_1 ≤ precise duration value_2</u> ≤ precise duration value_2 ≥ precise duration value_1

Definition: precise duration value quantifies duration and precise duration value quantifies

<u>duration</u>₂ and <u>duration</u>₁ ≤ <u>duration</u>₂

Example: "1 hour 30 minutes" is less than or equal to "2 days 30 minutes"

nominal duration value is less than or equal to nominal duration value

Synonymous Form: nominal duration value is greater than or equal to nominal duration value

Synonymous Form: nominal duration value₁ ≤ nominal duration value₂
Synonymous Form: nominal duration value₂ ≥ nominal duration value₁

Definition: nominal duration value quantifies duration value set 1 and nominal duration value2

quantifies <u>duration value set</u>2 and <u>duration value set</u>1 ≤ <u>duration value set</u>2

Example: "1 month 1 day" is less than or equal to "1 month 2 days"

precise duration value is less than or equal to nominal duration value

Synonymous Form: <u>precise duration value</u> ≤ <u>nominal duration value</u>

Synonymous Form: nominal duration value is greater than or equal to precise duration value

Synonymous Form: <u>nominal duration value</u> ≥ <u>precise duration value</u>

Definition: precise duration value quantifies duration and nominal duration value quantifies

duration value set and duration ≤ duration value set

Example: "366 days" is less than or equal to "1 year 1 day"

nominal duration value is less than or equal to precise duration value

Synonymous Form: nominal duration value ≤ precise duration value

Synonymous Form: <u>precise duration value</u> is greater than or equal to <u>nominal duration value</u>

Synonymous Form: <u>precise duration value</u> ≥ <u>nominal duration value</u>

Definition: nominal duration value quantifies duration value set and precise duration value

quantifies duration and duration value set ≤ duration

Example: "2 years 1 day" is less than or equal to "732 days"

precise duration value, is less than precise duration value,

Synonymous Form: precise duration value is greater than precise duration value

Synonymous Form: precise duration value₁ < precise duration value₂
Synonymous Form: precise duration value₂ > precise duration value₁

Definition: <u>precise duration value_1 quantifies duration_1 and precise duration value_2 quantifies</u>

<u>duration</u>₂ and <u>duration</u>₁ < <u>duration</u>₂

Example: "1 hour 30 minutes" is less than "91 minutes"

nominal duration value, is less than nominal duration value,

Synonymous Form: nominal duration value2 is greater than nominal duration value1

Synonymous Form: nominal duration value₁ < nominal duration value₂
Synonymous Form: nominal duration value₂ > nominal duration value₁

Definition: nominal duration value₁ quantifies duration value set₁ and nominal duration value₂

quantifies duration value set₂ and duration value set₁ < duration value set₂

Example: "1 month 1 day" is less than "1 month 2 days"

precise duration value is less than nominal duration value

Synonymous Form: <u>precise duration value</u> < <u>nominal duration value</u>

Synonymous Form: <u>nominal duration value</u> is greater than precise duration value

Synonymous Form: <u>nominal duration value</u> > <u>precise duration value</u>

Definition: <u>precise duration value quantifies duration and nominal duration value quantifies</u>

duration value set and duration < duration value set

Example: "366 days" is less than "1 year 2 days"

nominal duration value is less than precise duration value

Synonymous Form: <u>nominal duration value < precise duration value</u>

Synonymous Form: precise duration value is greater than nominal duration value

Synonymous Form: <u>precise duration value</u> > <u>nominal duration value</u>

Definition: nominal duration value quantifies duration value set and precise duration value

quantifies duration and duration value set < duration

Definition: "1 month 1 day" is less than "34 days"

9.5 Duration Value Sets

This sub clause defines the concept 'duration value set' and those relationships of that concept that are needed to semantically ground other features of this specification.

duration value set

Definition: set of duration values

Possibility: the <u>cardinality</u> of a <u>duration valueset</u> is <u>0</u>

Example: the duration value set that is quantified by {60 seconds 64 seconds}

The following concepts support comparison of two duration value sets.

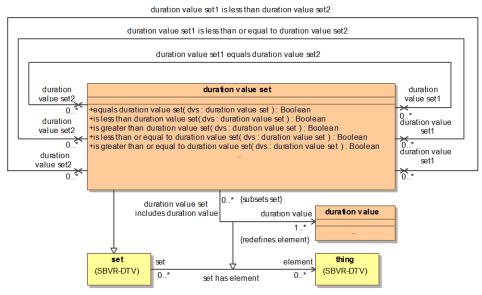

Figure 9.6 - Duration Value Set Comparisons

duration value set, equals duration value set,

duration value set 1 is equal to duration value set 2 Synonymous Form: Synonymous Form: duration value set 1 is equivalent to duration value set 2

Synonymous Form: duration value set1 = duration value set2

Definition:

each duration₁ of duration value set₁ = some duration₂ of duration value set₂ and each duration₂ of duration value set₁ = some duration₁ of duration value set₁ Example:

the duration value set {1 weeks} equals the duration value set {7 days, 14 days} the duration value set {1 day, 2 days} equals the duration value set {2 days, 1 day} Example:

duration value set is less than or equal to duration value set

Synonymous Form: duration value set2 is greater than or equal to duration value set1

Synonymous Form: $\underline{duration\ value\ set_1} \le \underline{duration\ value\ set_2}$ Synonymous Form: duration value set2 ≥ duration value set1

each duration value₁ of duration value set₁ is less than or equal to each duration Definition:

value₂ of duration value set₂

Example: the duration value set {1 day, 2 days} is less than or equal to the duration value set {2

days, 4 days)

duration value set, is less than duration value set,

<u>duration value set_2</u> is greater than <u>duration value set_1</u> Synonymous Form:

Synonymous Form: duration value set1 < duration value set2 Synonymous Form: duration value set₂ > duration value set₁

each <u>duration value_1</u> of <u>duration value set_1</u> is less than <u>each duration value_2</u> of Definition:

duration value set2

the duration value set {1 day, 2 days} is less than the duration value set {3 days, 4 days} Example:

Formatted: keyword Commented [EB65]: Issue 13-9 Correct markup Formatted: keyword

Durations can be compared with duration value sets.

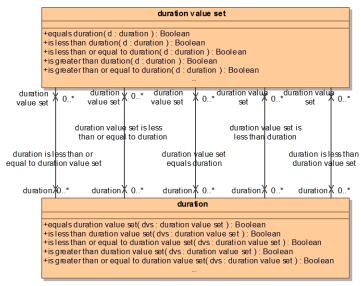

Figure 9.7 - Comparisons among Duration Value Sets and Durations

duration value set equals duration

Synonymous Form: duration = duration value set
Synonymous Form: duration value set = duration
Synonymous Form: duration equals duration value set
Synonymous Form: duration value set is equivalent to duration
Synonymous Form: duration is equivalent to duration value set

Definition: each <u>duration value of the duration value set</u> equals the given <u>duration</u>
Example: the <u>duration value set</u> {1 day} equals the <u>duration that is quantified by 1 day</u>

duration value set is less than or equal to duration

Synonymous Form: <u>duration</u> is greater than or equal to <u>duration value set</u>

Synonymous Form: <u>duration value set</u> ≤ <u>duration</u> Synonymous Form: <u>duration</u> ≥ <u>duration value set</u>

Definition: each <u>duration value</u> of the <u>duration value set</u> is less than or equal to the given

duration

Example: the <u>duration value set</u> {1 day, 2 days} is less than or equal to the <u>duration</u> that is

quantified by 2 days

duration is less than or equal to duration value set

Synonymous Form: <u>duration value set</u> is greater than or equal to <u>duration</u>

Synonymous Form: $\frac{\text{duration}}{\text{duration value set}} \le \frac{\text{duration value set}}{\text{duration value set}} \ge \frac{\text{duration}}{\text{duration value set}} \ge \frac{\text{duration}}{\text{duration value set}} \ge \frac{\text{duration}}{\text{duration value set}} \ge \frac{\text{duration value set}}{\text{duration value set}}$

Definition: duration is less than or equal to each duration value of the duration value set

Example: the duration that is quantified by 28 days is less than or equal to the duration value

<u>set</u> {28 days, 29 days}

duration value set is less than duration

Synonymous Form: <u>duration</u> is greater than <u>duration</u> value set

Synonymous Form: <u>duration value set < duration</u>
Synonymous Form: <u>duration > duration value set</u>

Definition:

Example:

each duration value of the duration value set is less than the given duration that is quantified by

3 days

duration is less than duration value set

Synonymous Form: <u>duration value set</u> is greater than <u>duration</u>

 $\begin{array}{lll} \mbox{Synonymous Form:} & \mbox{duration} < \mbox{duration value set} \\ \mbox{Synonymous Form:} & \mbox{duration value set} > \mbox{duration} \\ \end{array}$

Definition: <u>duration</u> is less than each <u>duration value</u> of the <u>duration value set</u>

Example: the <u>duration</u> that is quantified by <u>364 days</u> is less than the <u>duration value set {365</u>

days, 366 days

Specification of <u>compound nominal duration values</u> as <u>duration value sets</u> requires addition and subtraction among <u>durations</u> and <u>duration value sets</u>, and addition and subtraction among two <u>duration value sets</u>.

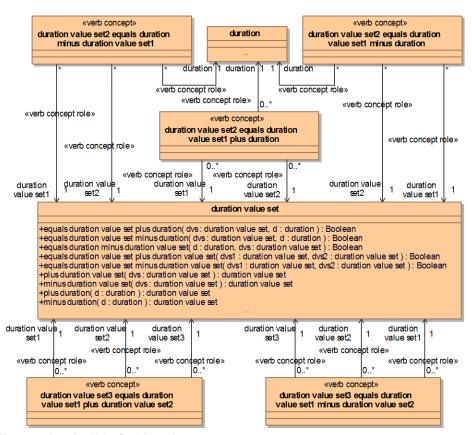

Figure 9.8 - Duration Value Set Arithmetic

duration value set₂ equals duration value set₁ plus duration

duration value set a equals duration plus duration value set
duration value set = duration value set + duration
duration value set ₂ = duration + duration value set₁
duration value set ₁ + duration
<u>duration</u> + <u>duration value set</u> ₁
duration plus duration value set₁
duration value set plus duration
each duration value ₂ of the duration value set ₂ equals some duration value ₁ of
<u>duration value set₁ plus the duration</u>
For each duration value set and for each duration, exactly one duration value set 2
is the duration value set plus the duration.
the <u>duration value set</u> {3 days, 4 days} equals the <u>duration</u> that is quantified by 2 days
plus the duration value set {1 day, 2 days}

Note: The result set disregards duplicates. Hence the <u>cardinality</u> of <u>duration value set</u>₃ may be

less than the product of the <u>cardinalities</u> of <u>duration value set</u>₁ and <u>duration value set</u>₂.

Necessity: For each <u>duration value set</u>₁ and for each <u>duration value set</u>₂ that <u>is less than or</u>

equal to duration value set₁, exactly one duration value set₃ is the duration value

set₁ minus the duration value set₂.

Example: the <u>duration value set</u> $\{-1 \text{ days}, 0 \text{ days}, 2 \text{ days}, 3 \text{ days}\} =$

the <u>duration value set</u> {3 days, 4 days} - the <u>duration value set</u>

{1 days, 4 days}

10 Calendars (normative)

10.1 General

Calendars use time scales to impose structure on time.

Calendars Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Included Vocabulary: <u>Time Infrastructure Vocabulary</u>

Namespace URI: http://www.omg.org/spec/DTV<u>{20160301</u>/dtv-sbvr.xml#CalendarsVocabulary

Deleted: 20150301

Commented [EB73]: Issue 13-9 INSERT text

10.2 Calendar Fundamentals

This sub clause contains definitions true of calendars in general.

Figure 10.1 - Calendars

calendar

Definition: Note:

Note: There are many different calendars, some standard, some cultural, some defined for

particular business needs.

Example: <u>Gregorian calendar</u>, lunar calendars, fiscal calendars, manufacturing calendars, tax calendars,

religious calendars.

Reference Scheme: the time scales that are defined by a calendar

calendar defines time scale

Synonymous Form: <u>time scale</u> is defined by <u>calendar</u>

Synonymous Form: <u>time scale of calendar</u>
Synonymous Form: <u>time scale on calendar</u>

Definition: the <u>calendar</u> specifies the details of the <u>time scale</u>

Example: The <u>Gregorian calendar</u> <u>defines</u> the <u>Gregorian year time scale</u> with other <u>time scales</u>.

10.3 Calendar Time Points and Time Periods

This sub clause defines categories of <u>time points</u> and <u>time periods</u> that <u>indicate time intervals</u> with <u>duration</u> '<u>day</u>', '<u>month</u>', or '<u>year</u>', but are independent of any particular calendar design. These concepts are intended to apply to religious and cultural calendars as well as the <u>Gregorian calendar</u>.

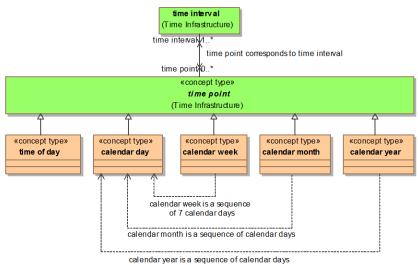

Figure 10.2 - Calendar Time Points

calendar year

Dictionary Basis: ISO 8601 (2.2.13, 'calendar year')

Concept Type: concept type

Definition: <u>time point that is defined by a given calendar</u> as a consecutive <u>sequence</u> of <u>calendar</u>

days, during which approximately one orbital rotation of the Earth around the Sun is

completed

Note: See "Gregorian year".

Example: the year 2008 (as defined by the Gregorian calendar)
Example: the 15th year of the reign of the Pharaoh Akhenaton

calendar month

Concept Type: concept type

Definition: time point that is defined by a given <u>calendar</u> as a consecutive <u>sequence</u> of <u>calendar</u>

days in a calendar year, during which approximately one rotation of the Moon in its orbit

around the Earth is completed

Example: August, 1945 (as defined by the Gregorian calendar) Ramadan in the 63rd year of the Prophet Mohammed Example:

calendar week

Concept Type: concept type

Definition: time point that is defined by a given calendar as 7 consecutive calendar days

Dictionary Basis: ISO 8601 (2.2.8, 'calendar week')

Note: ISO 8601 adds "starting on a Monday" to this definition. This vocabulary drops that phrase

because it is culture-specific.

This specification introduces two specific calendar week concepts: 'ISO week' and 'ISO Note:

week of year', both of which adopt the ISO 8601 convention that weeks start on Monday.

See Clause 12.

Example: The third calendar week of 2009.

calendar day

Concept Type: concept type

Definition: time point that is defined by a given calendar, and that corresponds to time intervals

during which approximately one revolution of the Earth occurs on its axis

Necessity: For each <u>calendar</u>, each <u>instance</u> of each <u>calendar day</u> that is defined by the

calendar is met by at most one instance of a calendar day that is defined by the

calendar.

July 4, 1776 (as defined by the Gregorian calendar) Example:

Example: The time period from sunrise in Rome on the Ides of March in the year 753 after the

founding of the City to the following sunrise.

time of day

Definition: time point that is on a time scale that has a granularity that is less than 1 day Note:

time of day time points are defined and discussed in detail in sub clause 13.2. The intent

here is that such time scales may be defined by a calendar.

Example: hour of day, second of minute

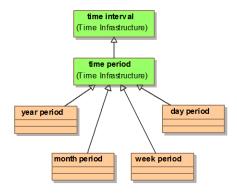

Figure 10.3 - Time periods based on calendars

year period

Dictionary Basis: ISO 8601 (2.2.14, note 1)

Definition: <u>time period</u> which starts at a certain <u>time of day</u> at a certain <u>calendar date</u> of the

<u>calendar year</u> and ends at the same <u>time of day</u> at the same <u>calendar date</u> of the next <u>calendar year</u>, if it exists. In other cases, the ending <u>calendar date</u> is defined by

agreement.

Note: A <u>calendar year</u> corresponds to <u>time periods</u> that start and end as defined by a <u>calendar</u>.

Note: A <u>year period</u> starts at any time within an instance of a <u>calendar year</u>.

Example: The concept "fiscal year" defined as the <u>year period</u> from <u>midnight</u> of <u>July1</u> of one

calendar year to midnight of July 1 of the following calendar year.

month period

Source: <u>ISO 8601</u> (2.2.12, note 1)

Definition: <u>time period</u> that starts at a certain <u>time of day</u> at a certain <u>calendar date</u> of the <u>calendar</u>

month and ends at the same time of day at the same calendar date of the next calendar

month, if it exists. In other cases, the ending <u>calendar date</u> is defined by agreement. A <u>calendar month</u> corresponds to <u>time periods</u> that start and end as defined by a

calendar.

Note: A month period starts at any time within an instance of a calendar month.

Example: From <u>July 15</u> at noon to <u>August 15</u> at noon.

week period

Note:

Definition: <u>time period</u> that starts at a certain <u>time of day</u> on a certain <u>calendar day</u> of the <u>calendar</u>

week and ends at the same time of day at the same calendar day of the next calendar

week.

Note: A <u>calendar week</u> is a period that starts and ends as defined by a <u>calendar</u>. A <u>weekperiod</u>

starts and ends at any time within a calendar week.

Example: <u>Tuesday</u> to <u>Tuesday</u>.

day period

Definition: time period that begins and ends at the same local time of day on consecutive calendar

days

Note: A <u>calendar day</u> corresponds to <u>time periods</u> that start and end as defined by a <u>calendar</u>.

Note: A <u>day period</u> starts at any time of day within an instance of a <u>calendar day</u>.

Note: A <u>day period</u> is defined by starting and ending at the same local <u>time of day</u>. When the

local

time of day is affected by a change of time offset between the starting and ending

time intervals, the day period can have a duration that is not 24 hours. The

duration of a

month period or a year period may also be affected by changes in the time offset

for the local time of day.

Example: Noon one <u>calendar day</u> to noon the following <u>calendar day</u>.

10.4 Time Point Subdivision

The purpose of <u>finite time scales</u> is to provide finer-grained resolution of time intervals within the time intervals that are instances of time points with coarser granularities. In this specification, the relationship between a finite time scale and a coarser time point is called "time point subdivision". Many finite time scales are defined by the category of time point they subdivide and the granularity of the time points they contain.

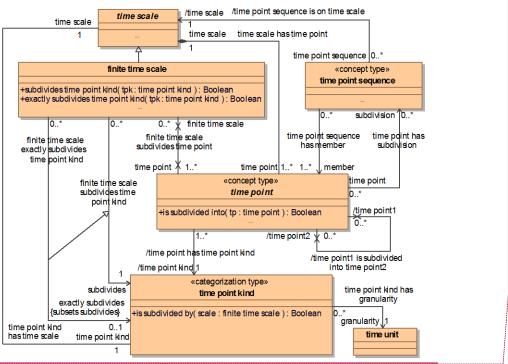

Figure 10.4 - Time Point Subdivision

time point kind

Concept Type: <u>categorization type</u>

Definition: concept that has an extension that is the set of members of exactly one time scale

Necessity: Each time point kind specializes the concept 'time point'.

Necessity: The concept 'time point kind' is a categorization type that is for the concept 'time

point

Note: 'Time point kind' is a partial categorization of 'time point'. A concept like 'time of day'

specializes 'time point', but its extension is not just the members of one time scale.

time point kind has time scale

Synonymous Form: <u>time scale</u> defines time point kind

Definition: each time point that is an instance of the time point kind is a member of the time

scale

 Necessity:
 Each time point kind has exactly one time scale.

 Necessity:
 Each time scale defines exactly one time point kind.

time point kind has granularity

Definition: the granularity is the granularity of the time scale of the time point kind

Necessity: Each time point kind has exactly one granularity.

finite time scale subdivides time point

Definition: each instance of the time point is an instance of a time point sequence that is on the

finite time scale and that has a first time point that is the index origin member of the

finite time scale

Note: This verb concept is defined primarily to simplify other definitions.

finite time scale subdivides time point kind

Definition: the finite time scale subdivides each time point that is an instance of the time point

kind

Note: This verb concept describes the purpose of the <u>finite time scale</u>: each <u>time point</u> of the

finite time scale corresponds to time intervals according to their position relative to the start of a time interval that is an instance of some time point of the time point kind. The first time point of the finite time scale corresponds to time intervals that start the larger time intervals and have a duration equal to the granularity of the finite time scale.

The granularity of each finite time scale is less than the granularity of each time

point kind that the finite time scale subdivides.

Note: The same <u>time point sequence</u> may be the subdivision of all time points of the <u>time point</u>

kind, or different time points may be subdivided into time point sequences of different

lengths.

Example: The <u>day of hours scale</u> <u>subdivides Gregorian calendar day</u>. Every time point that is a

Gregorian calendar day is subdivided into 24 hour of day time points, and each

corresponding time interval is divided into 24 time intervals, each of which is an instance

of one hour of day.

Note: The <u>time point sequence</u> may correspond to more time intervals than the instances of the

time point. For example, the <u>dayofhours</u> time scale subdivides (SO day of weet) and <u>day</u>

of month, but the time point sequence that is hour of day 0 to hour of day 23 corresponds

to every one day time interval, not just every Tuesday and every first of the month.

The Gregorian month of days scale subdivides month of year. Every time point that is a

Gregorian month of year is subdivided into some number of <u>day of month</u> time points, and

the time point sequences all begin with $\underline{\text{dayofmonth 1}}$, but the length of the time point

sequence depends on which month time point is subdivided.

subdivision

Example:

Necessity:

Concept Type: role

General Concept: time point sequence

Definition: time point sequence that is coextensive with a given time point

time point has subdivision

Definition:	the subdivision is a time point sequence that corresponds to each instance of the
	time point and that is on some finite time scale that subdivides the time point
Possibility:	A time point has no subdivision.
Possibility:	A time point has more than one subdivision

time point, is subdivided into time point,

Definition:	the subdivision of time point 1 includes time point 2	
Note:	This verb concept describes the relationship between a time point, and each individual time	
	point ₂ of a kind that subdivides it. In this specification it is used primarily to express the	
	<u>cardinality of subdivisions.</u>	
Example:	Gregorian day 3 January 2010 is subdivided into exactly 24 'hour of day' time points. The	
· ·	time interval corresponding to Gregorian date 3 January 2010 is implicitly subdivided into 24	

time intervals, each of which is an instance of one hour of day. But that same 24-hour

Commented [EB75]: Issue 13-66 REPLACE text

Commented [EB76]: Issue 13-25 REPLACE text

time point sequence is the subdivision of every Gregorian day, and it corresponds to every time interval that is an instance of a Gregorian day.

finite time scale exactly subdivides time point kind

Definition: for each time point that is an instance of time point kind, the time point sequence

that is the finite time scale corresponds to each time interval that is an instance of

the time point

Necessity: Each_finite time scale_that_exactly subdivides_a time point kind_subdivides_the_time

point kind.

Necessity: If a finite time scale exactly subdivides a time point kind 1, and each time point of the

finite time scale is an instance of a time point kind2, then the number of time point kind2 that each time point that is an instance of time point kind4 has is the cardinality

of the finite time scale.

Example: The day of hours scale exactly subdivides Gregorian day of month. Every Gregorian day of

month therefore has 24 of 'hour of day', because 24 is the cardinality of 'day of hours'.

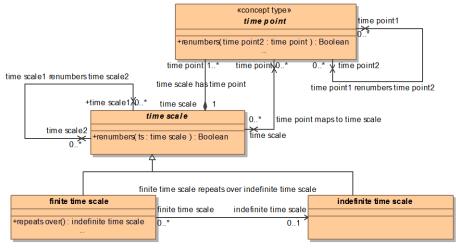

Figure 10.5 - Time Scale Renumbering

time point maps to time scale

Definition: the time point is not on the time scale and each time interval that is an instance of

the <u>time point</u> is an <u>instance</u> of some <u>time point</u> of the <u>time scale</u>

Note: This concept is introduced in order to simplify the definitions of time scale_1 renumbers

time scale₂ and time point₁ renumbers time point₂.

Example: Every <u>day-of-year</u> on the <u>year of days</u> time scale (see xxx) maps to the indefinite time scale

of calendar days. All of the time intervals involved are instances of <u>calendar day</u>.

time point, renumbers time point,

Synonymous Form: <u>time point</u> is renumbered by time point

Definition: time point maps to the time scale of time point and time point specializes time

point₁

Description: Every time interval that is an instance of time point is also an instance of time point

Possibility: A time point renumbers more than one time point.

Deleted: time point has number of time point kind the time point kind has a finite time scale and there is a time point sequence that is on the finite time scale and that corresponds to each instance of time point, and the first time point of the time point sequence is the index origin member of the finite time scale and the number is the cardinality of the time point sequence.

scale and an individual time point of the kind that the firite time scale subdivides. That is, it completely specifies the subdividing time point sequence.

If a time point has some number of time point kind, the finite time scale of time point kind, subdivides the time point kind, that the time point is an instance of.

that the time point is an instance of ¶
Gregorian day 3 January 2010 has 24 'hour of day time points. The time interval corresponding to Gregorian date 3 January 2010 is implicitly subdivided into 24+

time intervals, each of which is an instance of one bour of day. But that same 24-hour time point sequence is the subdivision of every Gregorian day, and it corresponds to every time interval that is an instance of a Gregorian day \P

Note: In particular, a time point on a finite time scale can renumber an indefinite number of time

points on an indefinite time scale

Example: Every day-of-year on the year of days time scale renumbers a set of time points on the

indefinite time scale of calendar days

time scale₁ renumbers time scale₂

each time point of time scale 1 renumbers some time point of time scale 2 and each Definition:

time point of time scale 2 is renumbered by some time point of time scale 1

Necessity: The granularity of each time scale that a time scale renumbers is the granularity of

time scale₁.

finite time scale repeats over indefinite time scale

Definition: the finite time scale renumbers the indefinite time scale and each time point of the

indefinite time scale is renumbered by the time point₃ that is on the finite time scale and that is just before the time point, that renumbers the time point, that is next after time point, if time point is not renumbered by the index origin member of the finite

time scale

Note:

Description: Consecutive time points on the finite time scale renumber consecutive time points on the

infinite time scale, and at some point the finite time scale starts over beginning with the

origin time point.

Note: Figure 10.6 shows the relationship of a finite time scale to an indefinite time scale that it

repeats over. The arrows show correspondence to time intervals.

The time points of the finite time scale, beginning at the origin, correspond to time intervals that are instances of time points on the indefinite time scale. So, in particular, time point O renumbers time point M and time point N, because it corresponds to the same time intervals. Further, time points M+1 and N+1 are renumbered by time point O+1, and similarly time points M+2 and N+2 are renumbered by time point O+2, and so on. This is the requirement stated in the definition above. Some "last" time point (T) on the finite time scale, however, renumbers the time point that is just before time point N, because the origin time point (O) renumbers time point N.

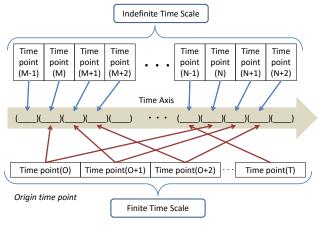

Figure 10.6 - Time point renumbering

It is possible that time point (T) does not renumber the time point that is just before time point (M). Some other time point on the finite time scale (e.g., T-1) may renumber that time point. It is not a requirement that the entire finite time scale is repeated in every instance.

101

For example, the month of days (finite) time scale renumbers the Gregorian days (indefinite) time scale. The month of days has 31 day of month time points, but the repeating process can start over after index 30, or 29, or 28, as well.

Commented [EB77]: Issue DTV 13-101 MOVE subclause 10.5 to clause 13 and revise text

Moved down [3]: Time Zones¶

Because of the rotation of the Earth, a separate calendar is needed for each time zone. In order to make local noon (12:00) coincide approximately with the Sun's zenith at the locale, authorities in each locale specify one or more calendars to be used, during different seasons of a year, for commerce in the locale. A locale in which a given calendar is used is called a "time zone." The governing authority over time zones is the national or state government of the locale. Many local calendars are named. For example, Pacific Day light Time, Eastern Standard Time, British Summer Time. Two or more time zones may have the same name, e.g., Eastern Standard Time in the U.S. (UTC-5 hours) and Australia (UTC+10 hours). It will not do merely to use UTC with a time offset of the UTC day of-hours scale for a local calendar: at any UTC time there is some locale that has a different local date that is one day before or after the UTC date: the date can be different as well as the hour and minute. For example, during periods when day light savings time is off in Australia (early April to early October), 18:00 UTC (19:00 BST in London) is 04:00 local time the next day in Sy dney (UTC+10 hours); 04:00 UTC is 18:00 local time the previous day in Honolulu (UTC-10 hours); Honolulu and Sydney, being 20 hours apart, are on different dates for all but four hours each day (10:00 -14:00 UTC that day). The approach adopted in this specification is to consider that each time zone has one or two distinguished local

calendars.¶
A local calendar is UTC with a characteristic time offset from UTC by up to ±12 hours. These offsets are usually an integer number of hours or half hours. The nominal offset is zero at the Prime Meridian, +1 hour for each 15° of longitude east of the Prime Meridian, and -1 hour for each 15° of longitude west of the Prime Meridian, '+' means a particular reading of a clock set to the time of the local calendar occurs before a clock that is set to UTC has the same reading; '-' means the local reading occurs after the UTC reading. The duration between corresponding readings is the time offset. The 180° meridian is nominally the International Date Line: a date in locales west of the International Date Line (e.g., longitude 179°E) is one day ahead of the date in locales east of the International Date Line (e.g., longitude 179°W.).¶

A complete literal specification of a time interval includes a calendar specification as part of the time coordinate; otherwise there is a 24 hour ambiguity. For example, compare "July 4, 2010 12:00 PDT" to "July 4, 2010 12:00" or "July 4, 2010 PDT" to "July 4, 2010." Note the 24-hour ambiguity when the calendar specification is left out, not knowing where in the world the time is meant.¶

The intended calendar is often implied by the locale of the utterance of a time coordinate, or by other context, but a calendar specification should be provided explicitly when necessary to remove all doubt. This is especially important in discourses that involve multiple time zones. When time coordinates are used in a discourse without specify ing the calendar, it is assumed for purposes of comparison and date-time arithmetic that they are on the same calendar. Time references without calendar specifications in different discourses also without locale references are not prima facie comparable to within less than 24 hours. ¶

A representation of a time offset may be combined with a date coordinate, a time of day coordinate, or a date time coordinate to indicate that the time coordinate is specified according to a calendar for a particular time zone or for day light savings time. The effect of the time offset is to shift the interpretation of the time coordinate with respect to UTC.¶

Definition: Note: Note:

Necessity:

10.6 Time Coordinates

A <u>time coordinate</u> is a conceptual structure of meaning that *refers to <u>time intervals</u>* using <u>time scales</u>. A time coordinate that refers to exactly one time interval is called an <u>absolute time coordinate</u>. When a time coordinate incorporates a year number, it is always an absolute time coordinate. For example, "January 3, 2011" refers to exactly one day over all time. A time coordinate that refers to more than one time interval is called a <u>relative time coordinate</u>. When a time coordinate omits the year, it is usually relative. For example, "January 3" refers to one day in every calendar year.

An <u>atomic time coordinate</u> is said to <u>indicate</u> a <u>time point</u> on some time scale, either by its name or by its number (called its <u>index</u>). For example, "January" indicates a Gregorian month of year time point, and "day of month 3" indicates a day of month time point. The atomic time coordinate <u>refers</u> to all the time intervals that are instances of that time point.

A <u>compound time coordinate</u> describes a category of the concept 'time interval', by *combining* multiple time coordinates to create a set of atomic time coordinates on different time scales. The compound time coordinate *refers to* the time intervals that are instances of the smallest granularity time point and that are contained in instances of the larger ones. For example, "July 1" is a compound time coordinate that refers to instances of 'day of month 1' that are part of an instance of July. Compound time coordinates don't always indicate time points. ("July 1" does not indicate a time point; because of leap years, it is not always the same day of year. "July 1, 2011", however, indicates a time point on the indefinite time scale of Gregorian days.)

Examples are "July1.201012:43:55", "Soweekofyear 41 ISOdayofweekof", and "1999 day 45". Clauses 11, 12, and 13 specify which combinations of atomic time coordinates form legitimate compound time coordinates. Invalid combinations typically omit intermediate time units. For example, "2011 12:43:55" makes no sense.

This specification does NOT specify how <u>time coordinates</u> are externally represented, for example on a monitor or in printed form. Many different external formats are employed among different languages and cultures. Representation formats are the choice of individual tools.

When more than one <u>time coordinate</u> refers to exactly the same <u>time intervals</u>, they are said to be equivalent. For example, "<u>January3,2011</u>" is equivalent to "<u>2011 day3</u>" because the two <u>time coordinates</u> refer to the same <u>calendar day</u> time interval. Determining equivalence is not easy because of the incorporation of <u>leap days</u> in some <u>calendar years</u>. For example, whether the 182nd day of the <u>calendar year</u> is before or the same as <u>July1</u> of the same <u>calendar year</u> depends upon whether the <u>calendar year</u> is a <u>leap year</u>.

10.6.1 General

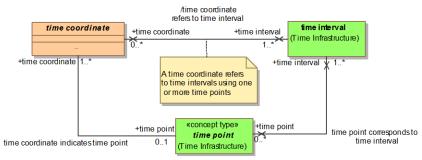

Figure 10.10 - Time Coordinate

time coordinate

Synonym: <u>time stamp</u>

Definition: conceptual structure of meaning that characterizes a category of the concept 'time interval'

Reference Scheme: an expression that represents the time coordinate

Example: <u>January 2009</u>, <u>2009 month 1</u>, <u>2009</u>

Note: Time coordinates may be either absolute or relative (see sub clause 10.6.2).

Note: Time coordinates may be either atomic or compound (see sub clause 10.6.3).

Necessity: Each time coordinate is either an absolute time coordinate or a relative time

coordinate.

Necessity: Each time coordinate is either an atomic time coordinate or a compound time

coordinate.

Note: Particular kinds of <u>time coordinates</u> are defined in Clauses 11, 12, and 13.

time coordinate indicates time point

Definition: the <u>time coordinate</u> characterizes the <u>time point</u>, either by instantiating a <u>reference</u>

<u>scheme</u> for the concept 'time point', or by characterizing the time intervals that the time

point corresponds to

Necessity: Each time coordinate indicates at most one time point.

Possibility: A time point is indicated by more than one time coordinate.

Note: Atomic time coordinates and compound time coordinates indicate time points in different

ways. Each is specified separately below.

Note: See 'compound time coordinate indicates time point' for definitions of exactly how a

compound time coordinate indicates a time point.

time coordinate refers to time interval

Note: The purpose of time coordinates is to identify time intervals, but atomic time coordinates

and compound time coordinates do that in different ways. So this concept is separately

defined for the two categories of time coordinate.

Necessity: Each <u>time coordinate</u> refers to at least one <u>time interval</u>.

10.6.2 Absolute and Relative Time Coordinates

It is convenient to distinguish between <u>absolute time coordinates</u> (time <u>coordinates</u> that include a <u>calendar year</u> and hence can be located on the <u>Time Axis</u>) and <u>relative time coordinates</u> (time <u>coordinates</u> that are relative to some larger <u>time unit</u>).

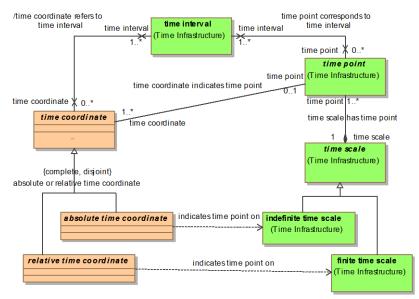

Figure 10.11 - Absolute and Relative Time Coordinates

absolute time coordinate

Definition: <u>time coordinate</u> that refers to exactly one <u>time interval</u>

Necessity: If an absolute time coordinate indicates a time point, the time point is on an

indefinite time scale.

Necessity: No absolute time coordinate is a relative time coordinate.

relative time coordinate

Definition: <u>time coordinate that refers to more than one time interval</u>

Necessity: If a relative time coordinate indicates a time point, the time point is on a finite time

scale.

Necessity: No relative time coordinate is an absolute time coordinate.

Note: A relative time coordinate refers to one time interval within each time period that is an

instance of some time point with a greater granularity (e.g., an hour of day is part of a calendar day). Thus the relative time coordinate "recurs" in each instance of the larger

time point.

Example: <u>12 November</u> (which recurs every calendar year)

10.6.3 Atomic and Compound Time Coordinates

As with <u>duration values</u>, <u>time coordinates</u> can be <u>atomic</u> (reference just one <u>time scale</u>, as in "<u>5p.m.</u>") or <u>compound</u> (referencing multiple <u>time scales</u>, as in "<u>5:00p.m.</u>", which combines an <u>hour-of-day</u> and a <u>minute-of-hour</u>).

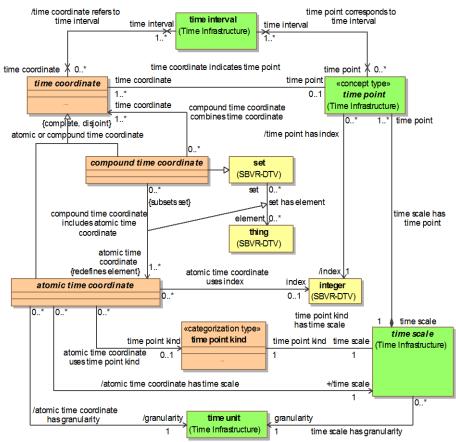

Figure 10.12 - Atomic and Compound Time Coordinates

atomic time coordinate

Definition:	time coordinate that is a term for a time point or that uses the index of a time point	
	and the time point kind of the time point.	
Necessity:	No atomic time coordinate is a compound time coordinate.	
Note:	The two possible forms for an atomic time coordinate are based on two of the reference	
	schemes for a time point. Expressions of these forms directly represent time points.	
Note:	In this specification, the syntax	
	<time kind="" point="" term=""> <index number=""></index></time>	
	indicates a time point by representing the atomic time coordinate that consists of the time	
	point kind of the time point and the index of the time point.	
Example:	<u>Tuesday</u>	
Example:	ISO week of year 53	
Example:	2010 (understood as a reference to the time point kind Gregorian year and index '2010')	

Commented [EB80]: Issue 13-66 REPLACE text

Deleted: , calendar week 53,

atomic time coordinate uses time point kind

Synonymous Form: <u>time point kind of atomic time coordinate</u>

Definition: the time scale of the time point kind is the time scale of the time point that the atomic

time coordinate indicates

 Necessity:
 Each atomic time coordinate uses at most one time point kind.

 Necessity:
 Each atomic time coordinate that uses a time point kind uses an index.

Note: Each time point kind is associated with exactly one time scale, and thus one set of time

points and their indices.

index

Concept Type: role
General Concept: integer

Definition: integer that is equal to the index of the time point that a given atomic time coordinate

indicates

atomic time coordinate uses index

Synonymous Form: <u>index of atomic time coordinate</u>

Definition: the index is an integer that is equal to the index of the time point that is indicated by

the atomic time coordinate

Necessity: Each atomic time coordinate uses at most one index.

Necessity: Each atomic time coordinate that uses an index uses a time point kind.

Note: The time point kind specifies a time scale. The index origin value and index origin member

of each time scale, which define the relationship of index values to time points, is specified in defining the time scale. In all relative time scales, the index origin member is the first member of the time scale. In the calendar time scales introduced in clauses 11, 12 and 13, the index origin value for Gregorian month of year, Gregorian day of month, Gregorian day of year, ISO week of year, and ISO day of week, use index origin value 1, while time-of-day scales (hour of day, minute of hour and second of minute) use index origin value 0. On the other hand, the index origin members and index origin values of absolute time scales are

established by tradition or treaty, and related to events.

atomic time coordinate indicates time point

General Concept: <u>time coordinate indicates time point</u>

Necessity: Each atomic time coordinate indicates exactly one time point.

Note: The following rules define how the two forms of atomic time coordinate indicate time

points.

Necessity: Each atomic time coordinate that is a term for a time point indicates the time point.

Necessity: Each atomic time coordinate that uses a time point kind and that uses an index

indicates the time point that is on the time scale of the time point kind and that has

an index that is equal to the index.

atomic time coordinate has time scale

Synonymous Form: <u>time scale</u> of <u>atomic time coordinate</u>

Definition: the time point that is indicated by the atomic time coordinate is on the time scale

Necessity: Each <u>atomic time coordinate</u> has exactly one <u>time scale</u>.

atomic time coordinate has granularity

Synonymous Form: granularity of atomic time coordinate

Definition: the granularity is the granularity of the time scale of the time point that is indicated

by the atomic time coordinate

Necessity: Each atomic time coordinate has exactly one granularity.

Commented [EB81]: Issue 13-66 REPLACE text

compound time coordinate

Definition: time coordinate that is a set of atomic time coordinates

 Necessity:
 The cardinality of each compound time coordinate is greater than 1.

 Necessity:
 No compound time coordinate is an atomic time coordinate.

 Necessity:
 A compound time coordinate refers to a time interval, if and only if

each time point that is indicated by an atomic time coordinate of the compound time coordinate corresponds to some time interval that includes time interval, and exactly one atomic time coordinate of the compound time coordinate indicates a

time point that corresponds to time interval₁.

Note: Each atomic time coordinate indicates one time point; and each time interval that the

compound time coordinate refers to is an instance of the time point with the smallest

granularity and is a part of some instance of each other time point.

Note: The set of time intervals to which a compound time coordinate refers may or may not be the

extension of some time point. "March 3 at noon" uses a compound time coordinate to refer to time intervals, but there is no corresponding time point. It refers to instances of <u>noon</u> that

are part of a March and part of a day of month 3.

Example: "January 2010" represents 'January' on the Gregorian year of months scale, and '2010' on

the <u>Gregorian years scale</u>, combined to *indicate* a particular <u>Gregorian month</u> on the

Gregorian months scale.

Example: "'<u>1 February</u>' is the first day of <u>February</u>' mentions (rather than uses) "<u>1 February</u>'. The

mention means '<u>February</u>' on the <u>Gregorian year of months scale</u>, '<u>day1</u>' on the <u>Gregorian month of days scale</u>, combined to <u>indicate Gregorian day32</u> on the

<u>Gregorian year of days scale</u>.

Example: "'1 March' is the first day of March" mentions (rather than uses) "1 March". The mention

means 'March' on the Gregorian year of months scale, 'day1' on the Gregorian month of days scale, combined to indicate the time set (Gregorian day 60, Gregorian day 61) on the Gregorian year of days scale. The time set models the idea that the meaning of "1 March"

depends upon whether it is a common year or a leap year.

Example: "Tax returns are due each 15 April." The quantifier and the use (rather than mention) of

"15 April" mean a set of Gregorian days, one in each Gregorian year.

compound time coordinate includes atomic time coordinate

Synonymous Form: <u>atomic time coordinate</u> of compound time coordinate
Synonymous Form: <u>atomic time coordinate</u> has atomic time coordinate

General Concept: set includes thing

Definition: the atomic time coordinate is an element of the compound time coordinate

Necessity: If a compound time coordinate includes an atomic time coordinate and an atomic

<u>time coordinate</u>₂ that is not <u>atomic time coordinate</u>₁, the <u>time scale</u> of <u>atomic time</u>

coordinate₁ is not the time scale of atomic time coordinate₂.

Note: That is, no two elements of a compound time coordinate indicate time points on the same

time scale.

Example: "2010 month 3" includes { Gregorian year 2010, Gregorian month of year 3} to indicate

Gregorian month 24111 and refer to its unique instance.

Compound time coordinates are constructed using the *combines* verb concept, which specifies a combination of <u>time</u> coordinates. The atomic time coordinates that are combined, and the atomic time coordinates that are elements of any compound time coordinates that are combined, together compose the set that is the <u>compound time coordinate</u>.

compound time coordinate combines time coordinate

Definition: if the time coordinate is an atomic time coordinate, the time coordinate is an element

of the compound time coordinate;

and if the time coordinate is a compound time coordinate, each atomic time coordinate of the time coordinate is an element of the compound time coordinate

Example: A <u>date time coordinate</u> combines a <u>date coordinate</u> and a <u>time of day coordinate</u>. The

date coordinate is a compound time coordinate that includes Gregorian year, month of year and day of month atomic time coordinates. The time of day may be given as hour of day and minute of hour atomic time coordinates. The set that is the date time coordinate includes exactly the year, month, day, hour, and minute atomic time coordinates.

compound time coordinate indicates time point

Synonymous Form: <u>time point</u> indicated by compound time coordinate

General Concept: <u>time coordinate indicates time point</u>

Definition: the compound time coordinate refers to each instance of the time point, and each

time interval that the compound time coordinate refers to is an instance of the time

point

Note: This definition says that a compound time point indicates any time point that is coextensive

with the category of time interval that the compound time coordinate characterizes. In practice, some algorithm relates the set of atomic time coordinates to a specific time point

on an entirely different time scale.

Possibility: A time point is indicated by more than one compound time coordinate.

Note: See sub clauses 11.6, 12.4, and 13.3 for details about how <u>atomic time coordinates are</u>

combined in the compound time coordinates that are defined by standard calendars.

Example: "January 4, 2010" indicates Gregorian day 733778

The meaning of every <u>time coordinate</u> is defined with respect to a particular <u>time scale</u>. For example, <u>year time coordinates</u> are defined on the <u>Gregorian years scale</u>. Commonly-used <u>time coordinates</u> are specified earlier in this document. Less commonly-used <u>time coordinates</u> are defined here.

 $A \ \underline{\text{time coordinate}} \ \text{can be} \ \underline{\text{absolute}} \ \text{or} \ \underline{\text{relative}}, \text{and} \ \underline{\text{atomic}} \ \text{or} \ \underline{\text{compound}}. \ This \ yields \ \text{four combinations}.$

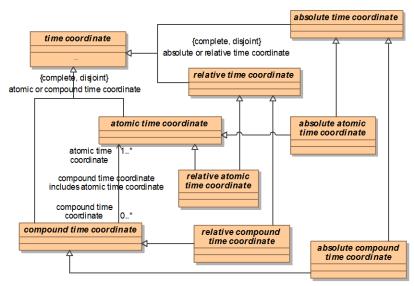

Figure 10.13 - Time Coordinate Types

absolute atomic time coordinate

Definition: absolute time coordinate that is an atomic time coordinate

Example: 2010

absolute compound time coordinate

Definition: absolute time coordinate that is a compound time coordinate

Example: 5 April 2010

relative atomic time coordinate

Definition: relative time coordinate that is an atomic time coordinate

Example:

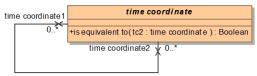

relative compound time coordinate

relative time coordinate that is a compound time coordinate Definition:

Example:

10.6.4 Time Coordinate Equivalence

Equivalence of time coordinates captures the idea that they can mean the same thing though given differently. For example, "February 15" and "day 46" are equivalent.

time coordinate1 is equivalent to time coordinate2

Figure 10.14 - Time Coordinate Equivalence

time coordinate, is equivalent to time coordinate,

Definition: time coordinate₁ refers to each time interval that time coordinate₂ refers to and time

coordinate2 refers to each time interval that time coordinate1 refers to

Necessity: If <u>time coordinate</u>₁ indicates some <u>time point</u>₁ and <u>time coordinate</u>₂ indicates some

time point2 then time point1 is time point2.

"<mark>2010 day3" is equivalent to "January3, 2010</mark>" Example:

"March" is equivalent to "month 3" Example:

Example:

"March 1" refers to the set {Gregorian day of year 60 in common years, Gregorian day of year 61

in leap years). Therefore March 1 is not equivalent to Gregorian day of year 61.

Time Sets 10.7

A time set represents a choice of one or more possible time point sequences on a given time scale. Each time point sequence may contain one or more time points. This concept models the idea that a relative time point may convert to one of several different time point sequences on a related relative time scale., depending on the absolute time point that the relative time scales subdivide.

In particular, every Gregorian month of year converts to a time set on the Gregorian year of days scale, which depends upon whether the Gregorian year is a common year or a leap year. The time set concept may be needed for other calendars with variable-length subdivisions.

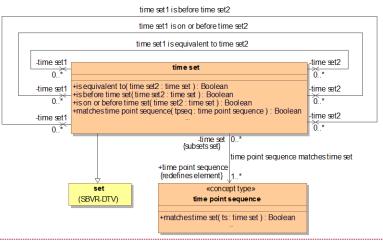

Figure 10.15 - Time Sets

time set

Definition: set of time point sequences

Necessity: the cardinality of a time set is greater than 0

Necessity: Some time scale₁ is the time scale of each time point sequence that is in a given

the time set {Gregorian day of year 59 Gregorian day of year 60} Example:

time set, is equivalent to time set,

Synonymous Form: time set1 equals time set2 Synonymous Form: time set₁ = time set₂

each $\underline{\text{time point }} \underline{\text{squence}}_1$ of $\underline{\text{time }} \underline{\text{set}}_1$ is $\underline{\text{some }} \underline{\text{time point }} \underline{\text{squence}}_2$ of $\underline{\text{time }} \underline{\text{set}}_2$ Definition:

and each time point sequence of time set is some time point sequence of time

set₁

Example: {<u>Gregorian day of year 59</u> through <u>Gregorian day of year 60</u>, <u>Gregorian day of year 60</u> through

<u>Gregorian day of year 61} is equivalent to {Gregorian day of year 60 through</u> <u>Gregorian day of year 61</u>, <u>Gregorian day of year 59</u> through <u>G</u>regorian day of year 60}

time point sequence matches time set

Synonymous Form: time set matches time period

General Concept: thing is in set

Definition: time point sequence is some time point sequence of time set

Example: <u>Gregorian day of year 60</u> matches <u>March 1</u> because <u>March 1</u> is either <u>Gregorian day of year 60</u> or

Gregorian day of year 61

Commented [EB82]: Issue 13-66 REPLACE text

Deleted: A 'time set' represents a choice of one or more possible time point sequences on a time scale. Each time point sequence may contain one or multiple time points. This concept models the idea that a relative time coordinate may convert to a choice of several time point sequences. In particular, the following kinds of time points convert to time sets on the Gregorian year of day scale depending upon whether the year is a common year or a leap year, or upon which calendar day is the first week day of the first ISO week of year of the Gregorian year.¶
→every Gregorian month that is after January

→every ISO week of year • every ISO weekday of year¶

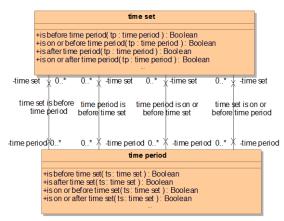

Figure 10.16 - Time Set Relations

time set, is on or before time set,

Synonymous Form: <u>time set_2</u> is on or after time set_1

Gregorian day of year 103

time set is before time period

Synonymous Form: time period is after time set time set < time period > time period > time set

Definition: the time interval that instantiates each time point sequence of time set precedes

time period

Example: {Gregorian day of year 102 through Gregorian day of year 103} is before

Gregorian day of year 104

10.8 Dates and Times of Day

The most common references to specific time intervals are to specific days (calendar days) and to specific times of day. This section introduces the general concepts calendar date(coordinate), which refers to a calendar day, and time-of day coordinate, which refers to a specific time-period within a calendar day. A calendar date may be combined with a time-of day coordinate to produce a date time-coordinate.

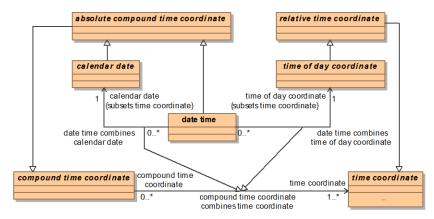

Figure 10.17 - Date and time coordinates

calendar date

Synonym: date

Synonym: date coordinate

Synonym: <u>calendar date coordinate</u>

Definition: absolute time coordinate that indicates a calendar day
Note: Most calendar dates are compound time coordinates.

Example: The Gregorian date coordinate "January 25, 2012" is a calendar date.

time of day coordinate

Definition: relative time coordinate that indicates a time of day

Note: Each time of day coordinate indicates a time point on a finite time scale whose granularity is

smaller than 1 day. That is, a time of day coordinate refers to time intervals that are within a

calendar day.

Example: The standard time coordinate "15:00" is a time of day coordinate.

date time

Synonym: <u>date time coordinate</u>

Synonym: <u>date and time</u>

Definition: absolute compound time coordinate that combines a calendar date and that

combines a time of day coordinate

Necessity: Each <u>date time</u> refers to exactly one <u>time interval</u>.

Necessity: Each date time refers to the time interval that the time of day coordinate of the date

time refers to and that is during the time interval that the calendar date of the date

time refers to.

Note: That is, the <u>date time</u> refers to the unique time interval that is at that time of day and on that

date.

 Example:
 June 9, 1990 5:49:03 p.m.

 Example:
 13:00 on 1949 day 53

 Example:
 6 p.m. on 2010 August 6

date time combines calendar date

Synonymous Form: <u>calendar date</u> of <u>date time</u>

General Concept: <u>compound time coordinate</u> <u>combines time coordinate</u>

Note: This verb concept wording provides a term for the date coordinate that the date time

combines.

Necessity: Each date time combines exactly one calendar date.

date time combines time of day coordinate

Synonymous Form: <u>time of day coordinate</u> of <u>date time</u>

General Concept: compound time coordinate combines time coordinate

Note: This verb concept wording provides a term for the time of day coordinate that the date time

combines.

Necessity: Each date time combines exactly one time of day coordinate.

10.9 Time Scale Comparison and Conversion

Two <u>time points</u> are commensurable (comparable) if and only if they are on the same <u>time scale</u>, or can both be converted to a <u>common time scale</u>. For example, "<u>hour 10</u>" is commensurable with "<u>11:30</u>" because "<u>hour 10</u>" can be converted to a <u>minute of day on the day of minutes scale</u>, and "<u>11:30</u>" is on already that <u>time scale</u>. "<u>hour 10</u>" is not commensurable with "<u>March</u>" because they cannot be converted to any <u>common time scale</u>.

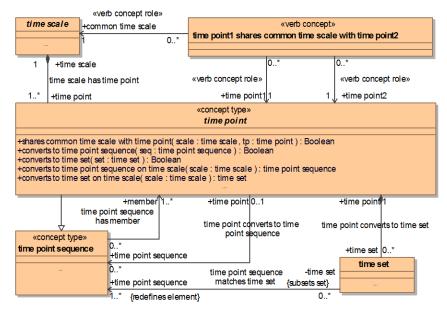

Figure 10.18 - Time Scale Commonality and Conversion

The concept "time point₁ shares common scale with time point₂" is used below to declare specific combinations of time points that can be compared if they are converted to particular common time scales. Other combinations are not commensurable.

common time scale

Concept Type: role
General Concept: time scale

time point, shares common time scale with time point,

Definition:

some time point sequence₁ on the common time scale corresponds to each time period that instantiates time point₁ and some time point sequence₂ on the common time scale corresponds to each time period that instantiates time point₂

The concept "time point converts to time point sequence" describes conversion of a time point on some time scale₁, to a time point sequence on some time scale₂. The time point and the time point sequence correspond to the same time intervals. The target time scale₂ always has a granularity that is less than or equal to the granularity of time scale₁. For example, the Gregorian month of year that is indicated by "January" (on the Gregorian year of months scale) converts to the time point sequence from Gregorian day of year 1 through Gregorian day of year 31 on the Gregorian year of days scale.

Clause 11.8 uses this concept to define specific conversions for Gregorian calendar time points. The concept applies to absolute time points and relative time points.

time point converts to time point sequence

Definition: the time point is coextensive with the time point sequence

Necessity: The granularity of the time scale of a time point is greater than the granularity of the

time scale of each time point sequence that the time point converts to.

Possibility: A time point that converts to a time point sequence is an absolute time point or is a

relative time point.

Description: The <u>time point</u> and the <u>time point sequence</u> are two different ways to identify the same

time intervals.

Note: The method _ "time point". _ "converted to time scale" returns the time

point sequence(s) that the time point converts to on the given time scale. It is provided for

convenience in formulating OCL rules.

Note: The specific conversions supported by this document are defined below in verb concepts

that specialize "time coordinate converts to time point sequence on time scale."

Example: The <u>time point</u> that *is indicated by* the <u>time coordinate January 2012 converts to the time</u>

point sequence 2012 day 1 through 2012 day 31 on the Gregorian days scale.

time point converts to time set

Definition: each instance of the time point is an instance of at least one time point sequence of

the time set

Necessity: The granularity of the time scale of a time point is greater than the granularity of the

time scale of each time point sequence that is in a time set that the time point

converts to.

Possibility: A time point that converts to a time set is an absolute time point or is a relative time

point.

Description: The time scale is defined with discontinuities (e.g., leap days), such that the time set

identifies several alternative time intervals that may correspond to the time point.

Example: The <u>time point</u> that is indicated by the <u>time coordinate</u> <u>'February'</u> converts to the <u>time</u>

set (Gregorian day of year 32 through Gregorian day of year 59, Gregorian day of year 32 through

Gregorian day of year 60} on the Gregorian year of days scale.

compound time coordinate converts to time set on time scale

Definition: each time point sequence of the time set corresponds to some time interval that the

compound time coordinate refers to, and each time interval that the compound time coordinate refers to is an instance of exactly one time point sequence of the time set

Note: In most cases of interest, each of the time point sequences will consist of a single time point.

Example: "15 June" refers to one calendar day in each Gregorian year, but in common years it is Gregoriandayofyear 165 and in leap years it is Gregoriandayofyear 166. So, "15 June" converts to the time set { Gregoriandayofyear 165, Gregoriandayofyear 166} on the

Gregorian year of days scale.

10.10 Mixed Base Time Arithmetic

Addition of a <u>duration value</u> to a <u>time coordinate</u>, subtraction of a <u>duration value</u> from a <u>time coordinate</u>, and subtraction of one <u>time coordinate</u> from another all employ "mixed-based time arithmetic." This is an extension of traditional mixed-base arithmetic as employed, for example, in the old-style English currency of pounds, shillings, and pence. The variation of mixed-base arithmetic that is described here accommodates the special issues raised by the nominal <u>time units</u> '<u>year</u>' and '<u>month</u>', and by the fact that '<u>week</u>' is incommensurate with '<u>year</u>'. This procedure is described in text, rather than as a set of SBVR concept definitions, because SBVR is not adapted to defining complex procedures.

Both addition and subtraction apply from the start of a <u>time coordinate</u>. For example, " $\underline{9 \text{ April}} + \underline{10 \text{ hours}}$ " is " $\underline{9 \text{ April}} 10.00$ ", while " $\underline{9 \text{ April}} - \underline{10 \text{ hours}}$ " is " $\underline{8 \text{ April}} 14.00$ ".

Mixed-base arithmetic is performed by separately adding or subtracting the individual components of a time coordinate, and then, if necessary, performing a "carry" (for addition) or "borrow" (for subtraction) from the number of the

<u>atomic time coordinate</u> that has the next coarser <u>time unit</u>. The result may be either compound or atomic. For example, " $\frac{9 \text{ days } 20 \text{ minutes}}{20 \text{ minutes}} = \frac{6 \text{ days } 13 \text{ hours } 27 \text{ minutes}}{20 \text{ minutes}} + \frac{2 \text{ days } 10 \text{ hours } 53 \text{ minutes}}{20 \text{ minutes}}$ " by the following steps:

```
\underline{27 \text{ minutes}} + \underline{53 \text{ minutes}} \Rightarrow \underline{80 \text{ minutes}} \Rightarrow \underline{20 \text{ minutes}} with \underline{1 \text{ hour}} carry \underline{13 \text{ hours}} + \underline{10 \text{ hours}} + \underline{1 \text{ hour}} carry \Rightarrow \underline{24 \text{ hours}} \Rightarrow \underline{0 \text{ hours}} with \underline{1 \text{ day}} carry \underline{6 \text{ days}} + \underline{2 \text{ days}} + \underline{1 \text{ day}} carry \Rightarrow \underline{9 \text{ days}}
```

The following list gives equivalences among most of the precise time units for use in determining when "carries" and "borrows" are needed. Equivalences between years and years and

```
Each minute is equivalent to 60 seconds.

Each hour is equivalent to 60 minutes.

Each day is equivalent to 24 hours.

Each week is equivalent to 7 days.

Each year is equivalent to 12 months.
```

A "carry" is applied if the <u>number</u> of an <u>atomic time coordinate</u> that is formed as an intermediate calculation result is greater than shown in the equivalences given above. To perform a "carry," divide the <u>number</u> of the intermediate result by the equivalence shown above, add the result to the <u>number</u> of the notional next coarser <u>atomic time coordinate</u> (which may be $\underline{0}$), and set the <u>number</u> of the finer component to the remainder. Note that "carries" may propagate across multiple components. See the example given above.

A "borrow" is performed if the <u>number</u> of an <u>atomic time coordinate</u>, formed as an intermediate calculation result, is negative. To apply a "borrow," divide the number of the absolute value of the intermediate result by the equivalence shown above, subtract the result for the <u>number</u> of the notional next coarser <u>atomic time coordinate</u> (which may be $\underline{0}$), and set the the <u>number</u> of the finer component to the remainder. Note that "borrows" may propagate across multiple components. For example, " $\underline{22\,\text{minutes}\,15\,\text{seconds}} = \underline{35\,\text{minutes}} - \underline{12\,\text{minutes}\,45\,\text{seconds}}$ " by the following steps:

```
\frac{0 \text{ seconds}}{35 \text{ minutes}} − \frac{45 \text{ seconds}}{12 \text{ minute}} 1 \frac{1 \text{ minute}}{12 \text{ minute}} borrow \frac{12 \text{ minute}}{12 \text{ minute}} borrow
```

The procedure described above works even when an atomic duration value has a number that is greater than an equivalence shown above. For example, " $\frac{23 \text{ hours}}{23 \text{ hours}} = \frac{2 \text{ days}}{25 \text{ hours}}$ ".

When adding or subtracting values of 'days' from time coordinates of the nominal time units 'year' and 'month', the interpretation of any "carries" or "borrows" depends upon the particular year or month coordinate. For a year coordinate, a "carry" occurs if the number of days exceeds $\frac{365}{6}$ for a common year, and $\frac{366}{6}$ for a leap year, and a "borrow" is made from $\frac{365}{3}$ if the year is a common year, and from $\frac{366}{3}$ otherwise. For example, " $\frac{2007 \text{ day}331}{2000} = \frac{2008}{3000} - \frac{35 \text{ days}}{3000}$ " but " $\frac{2006}{3000}$ day $\frac{300}{3000} = \frac{2007}{3000} - \frac{35 \text{ days}}{3000}$ ".

For a month coordinate, "carries" and "borrow" are made according to the following number of days per particular calendar month:

Table 10.1 - Number of Calendar Days per Gregorian Month

<u>Gregorian Month</u>	Equivalent Number of <u>Calendar Days</u>
<u>February</u>	28 in common years, 29 in leap years
April, June, September, November	<u>30</u>
January, March, May, July, August, October, December	<u>31</u>

Note that, in some cases, repeated "carries" or "borrows" may be required across multiple calendar months. For example, " $\frac{2 \text{ March } 2010}{2 \text{ March } 2010} = \frac{31 \text{ January } 2010}{2 \text{ January } 2010} + \frac{30 \text{ days}}{2 \text{ January } 2010}$.

Subtraction is defined for most combinations of two time coordinates. For example,

"30 days = 2 March 2010 - 31 January 2010". However, subtraction of date coordinates that span the end of February is not defined if the calendar years are not specified. For example, "3 days = 2 February - 30 January" but "2 March - 28 February" is either "2 days" or "3 days" depending upon whether these dates are in a leap year or not.

Arithmetic involving weeks and years presents a special problem - determine which concept of 'year' is intended. That is because the Gregorian year (clause 11) and the <u>ISO</u> week-based year (clause 12) are of different lengths and are only loosely aligned.

When the time coordinates are Gregorian time coordinates, additions and subtractions involving years, months, weeks, and days is done in Gregorian terms, treating each week as 7 days. For example: 20 December 2008 plus 1 year and 8 weeks is 20 December 2009 + 56 days = 14 February 2010.

When the time coordinates are ISO year week or ISO year week day coordinates, additions and subtractions involving years and weeks is done in terms of the SO week-based year. That is, each 'year' that is added or subtracted is taken to be exactly 52 weeks or exactly 53 weeks, according to the "First Thursday Rule" (see 12.2). For example: "2008 week 50 plus 1 year and 8 weeks" is 2009 week 50 plus 8 weeks = 2010 week 5. Following the logic above, week 50 + 8 weeks gives 58 weeks, which causes a carry into the 'year' position. But Gregorian year 2009 started on a Thursday, so the ISO week-based year 2009 has 53 weeks, and the residue is 5 weeks. By comparison, 2010 week 50 plus 8 weeks is 2011 week 6, because the ISO week-based year 2010 has only 52 weeks.

The <u>ISO</u> day of week is not affected by variation in the duration of <u>ISO</u> week-based years. Every week has exactly 7 days. Carrying or borrowing out of the 'day' (of week) position modifies the <u>ISO</u> week of year value in the obvious way.

Additions or subtractions to relative <u>ISO week of year coordinates</u> and <u>ISO week-day coordinates</u> that carry or borrow into the 'years' position is not well-defined. Some <u>ISO</u> week-based years have 52 weeks and some have 53.

Explicit subtraction between Gregorian calendar time coordinates and SO weeks calendar time coordinates is best accomplished by reducing both time coordinates to indices on the indefinite scale of Gregorian days. The difference is then an exact duration in days, which can be converted to any convenient compound duration value.

Deleted: The Gregorian calendar is standardized in SO 8601

Commented [EB85]: Issue 13-69 REPLACE Figure

Definition: calendar in general use, introduced in 1582 to define a calendar year that more closely

approximated the tropical year than the Julian calendar
The <u>Gregorian Calendar</u> was defined in 1582 in [Inter Gravissimas] and was adopted at Note:

various times by various countries. It is now the international standard calendar.

Note: The interpretation of any date depends upon the calendar used. Caution should be used

with historical dates because the standard calendar varied by locality as well as time. The <u>Gregorian Calendar</u> was adopted in <u>1582</u> in Italy and a few other countries, and at various

times as late as 1926 in other countries.

Convention du Mètre

occurrence that is the signing of the Convention du Mètre Definition: Necessity: The Convention du Mètre occurred within 20 May 187

The particular Gregorian day on which the signing of the Convention du Mètre occurred Note:

establishes the index origin of the various Gregorian scales.

[ISO 8601] establishes the date of the signing of the Convention du Mètre, 20 May 1875, as Note:

the reference date for the Gregorian calendar.

Gregorian years scale

Definition: the indefinite time scale that has granularity year and that has time points that are

Gregorian years

The index origin value of the Gregorian years scale equals 1875. Necessity:

Necessity: The time interval that Gregorian year 1875 corresponds to is started by the time

interval that is the Gregorian day 684 467.

Gregorian day 684 467 is January 1, 1875. Note:

Note: The starting Gregorian day and the rules for the duration of Gregorian years define a unique

time interval.

This definition applies to the Gregorian calendar as recognized at the Prime Meridian at Note:

Greenwich in England during Standard Time. Other Gregorian years scales may be obtained by adding or subtracting time offsets, as discussed in sub clause 13.5.

Gregorian months scale

Definition: the indefinite time scale that has granularity month and that has time points that are

Gregorian months

Necessity: The index origin value of the Gregorian months scale equals 22 493

22 493 is 12 * (1875 - 1) + 5 (for the month of May) Note:

The time interval that Gregorian month 22493 corresponds to is a May and is started Necessity:

by the time interval that is the Gregorian day 684 587.

Gregorian day 684 587 is May 1, 1875. Note: Note:

The starting Gregorian day, and the fact that the Gregorian month is a May (and therefore

has 31 days) defines a unique time interval.

This definition applies to the Gregorian calendar as recognized at the Prime Meridian at Note:

Greenwich in England during Standard Time. Other Gregorian months scales may be obtained by adding or subtracting time offsets, as discussed in sub clause 13.5.

Gregorian days scale

Definition: the indefinite time scale that has granularity day and that has time points that are

Gregorian days

The index origin value of the Gregorian days scale equals 684606 Necessity:

Gregorian day 684 606 is May 20, 1875. Note:

Note: The calendar reform instituted by Pope Gregory XIII and promulgated in the bull [Inter

Gravissimas] started the use of the Gregorian calendar with the date 15 October 1582, which is the same as 05 October 1582 in the Julian calendar. That calendar day had index 577 738

on the Julian calendar, computed as 1581 years of 365 days plus 395 leap days from 1 January of year 1 (calendar day $\underline{1}$) to 1 January 1582 + 277 days from 1 January 1582 to 5 October 1582. From 15 October 1582 to the Convention du Mètre on 20 May 1875, there were 106 868 calendar days (including leap days). Therefore, the Convention happened on calendar day 684 606 of the <u>Gregorian days scale</u>.

The Convention du Mètre occurred within the time interval that is the Gregorian day

<u>684 606</u>.

Necessity:

Note:

Note:

Necessity: The <u>duration</u> of the <u>time interval</u> that is the <u>Gregorian day 684606</u> is <u>1 day</u>.

Necessity: The <u>time interval</u> that is the <u>Gregorian day 684606</u> is <u>started by a time interval</u> that is

the 12 hours preceding an observation of noon at the Greenwich observatory.

The combination of the above necessities identifies a unique time interval. The reference origin for the Gregorian months scale and the Gregorian years scale are defined in terms of that

time interval.

Note: Noon at the Greenwich observatory was the reference point for Gregorian days until 1884.

The [International Meridian Conference] of 1884 established the Greenwich Meridian as the international standard for zero degrees longitude. It also established a uniform international

time standard called the 'universal day' – a mean solar day of 24 hours measured from midnight on the Greenwich Meridian. This time standard was formally replaced by Universal Coordinated Time in 1972.

This definition applies to the <u>Gregorian calendar</u> as recognized at the Prime Meridian at Greenwich in England during Standard Time. Other <u>Gregorian days scales</u> may be obtained by adding or subtracting <u>time offsets</u>, as discussed in sub clause 13.5.

Definition: Gregorian month or Gregorian month of year

Concept Type: concept type

Gregorian day

Concept Type: concept type

Definition: calendar day that is on the Gregorian days scale

Note: This is an <u>absolute time point</u> because it is on an <u>indefinite time scale</u>.

Gregorian day of year

Concept Type: concept type

Definition:

Note:

This is a relative time point because it is on a finite time scale.

Necessity:

Recessity:

In general each Gregorian day of year corresponds to one calendar day in each Gregorian year but Gregorian day of year 366 occurs only in leap years.

Gregorian day of month

Concept Type: <u>concept type</u>

Definition: calendar day that is on the Gregorian month of days scale

Note: This is a relative time point because it is on a finite time scale.

 Necessity:
 Each Gregorian day of month corresponds to a set of Gregorian days.

 Note:
 In general each Gregorian day of month corresponds to one calendar day in each

Gregorian month but Gregorian day of month 29, 30, and 31 do not occur in every

Gregorian month.

Gregorian calendar day

Definition: Gregorian day or Gregorian day of year or Gregorian day of month

Concept Type: concept type

11.4 Gregorian Months<mark>of Year</mark>

Because of the cyclic usage of the finite time scales associated with calendars, the names of months, days of the week, and holidays designate many time intervals and so are general concepts. However, these names are traditionally capitalized like proper names and also seem like individual concepts. [Using this specification, when the name of a time point is used, it designates the general concept (the time point) and denotes the corresponding time intervals, in the same way that a term for any general concept denotes its instances. Such usage commonly involves quantifiers and qualifiers, such as "every April" or "next April" or "April (in) 2001", which select specific time intervals. When the intent is to refer to the time point itself – the individual thing that appears on the calendar – the name is qualified as referring to a time point, as in "the time point 'April'," or "the Gregorian month of year 'April'," which is a short form of "the Gregorian month of year that is designated by 'April'."

All named time points are treated in this way, including the Gregorian months of year, the days-of-week, and recurring holidays and anniversaries.

Some holidays, like Easter and Ramadan, recur irregularly, so additional information, such as an ephemeris, is required to resolve the name to particular Gregorian <u>calendar dates</u>. Formalizing such definitions is beyond the scope of this specification.

The following defines the common names for <u>Gregorian month of years</u> as individual concepts because they identify specific months on the <u>Gregorian year of months scale</u>.

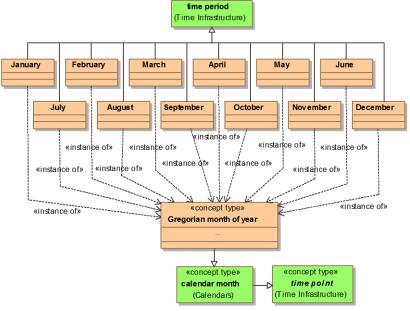

Figure 11.4 - Gregorian Months

Commented [EB90]: Issue DTV 13-103 Change Title

Commented [EB91]: Issue DTV 13-103 REPLACE text

Deleted: This illustrates a dilemma: the names of <u>calendar</u> <u>periods</u> are homony ms. The multiple meanings of such names can be understood by considering that each such name can refer to a <u>set</u> of <u>time points</u> collectively, to any member of such a <u>set</u>, or to a unique <u>time point</u> on a firite time <u>scale</u>. For example, "Tuesday" can refer to the <u>set</u> of all <u>Tuesdays</u> (time <u>points</u>), to a member of the <u>set</u> of time <u>points</u>, or to a unique <u>to the set</u> of time <u>points</u>.

time point on the finite week-of-days scale. To resolve the homony m when using this specification, when a name of a calendar period is used, it is, by default, assumed to designate a general concept of time points. Such usage commonly involves quantifiers, such as "every Tuesday" or "next Tuesday" that select particular time points, and reference particular time intervals, like quantified variables in first order predicate logic. When the unique time point is meant, the name is mentioned (by quoting it) and is qualified as referring to a time point, as in "the time point Tuesday"."

<u>Calendar period</u> names that are treated in this way include the month names, the day-of-weeknames, and recurring holiday or anniversary names.

January

Source: ISO 8601 (Table 1)

Definition: time interval that has duration 31 days and that starts an instance of a Gregorian year

The concept 'January' is the Gregorian month of year that is in sequence position 1 Necessity:

of the Gregorian year of months scale

The time point 'January' subdivides into exactly 31 Gregorian days of month. Necessity:

Each January is met by a December. Necessity:

Note:

"<u>January 2008</u>" and "<u>2008 month 01</u>" are expressions for a <u>calendar date</u>
"<u>January 2008</u>" is an expression for a <u>calendar date</u> for a <u>Gregorian month of year</u> using Note:

a reference scheme involving a Gregorian month and a calendar year.

February

ISO 8601 (Table 1) Source: Definition:

time interval that is met by a January and that has a duration that is 28 days if the

time interval is part of an instance of a common year, or that is 29 days if the time

interval is part of an instance of a leap year

The time point 'February' subdivides into exactly 28 Gregorian days of month or Necessity:

exactly 29 Gregorian days of month.

The time point sequence that is Gregorian day of month 1 through Necessity:

<u>Gregorian dayof month 28 corresponds to each February that is during a common year.</u>

Necessity: The time point sequence that is Gregorian day of month 1 through

Gregorian day of month 29 corresponds to each February that is during a leap year.

The set of these two time point sequences is how Gregorian month of days subdivides Note:

The subdivision of the time point is fixed. day-of-month 29 is part of the sequence, but not Note:

every February has 29 day-of-month subintervals.

The rules for leap years were established by Pope Gregory XIII in [Inter Gravissimas]. Note:

These rules were eventually adopted by various civil governments and incorporated into

[ISO 8601].

March

ISO 8601 (Table 1) Source:

time interval that is met by a February and that has a duration that is 31 days Definition:

Necessity: The concept 'March' is the Gregorian month of year that is in sequence position 3 of

the Gregorian year of months scale.
The time point 'March' subdivides into exactly 31 Gregorian days of month. Necessity:

<u>April</u>

ISO 8601 (Table 1) Source:

Definition: time interval that is met by a March and that has a duration that is 30 days

Necessity: The concept 'April' is the Gregorian month of year that is in sequence position 4 of

the <u>Gregorian year of months scale</u>.

The time point 'April' <u>subdivides into exactly 30 Gregorian days of month.</u>

May

Source: ISO 8601 (Table 1)

time interval that is met by an April and that has a duration that is 31 days Definition:

Necessity: The concept 'May' is the Gregorian month of year that is in sequence position 5 of

the Gregorian year of months scale

The time point 'May' subdivides into exactly 31 Gregorian days of month. Necessity:

11.5 Gregorian Year Values

This sub clause defines the meaning of <u>nominal atomic duration values</u> that use the <u>nominal time</u> unit '<u>year</u>'. It accounts for the varying numbers of <u>calendar days</u> in <u>Gregorian years</u>, due to <u>leap years</u>, <u>centennial years</u>, and <u>quadricentennial years</u>.

Note: this sub clause defines some concepts, such as 'year remainder', that are only needed to support the concept 'year value specifies duration value set'. These supporting concepts need not be explicitly defined in versions of this specification in other modeling systems.

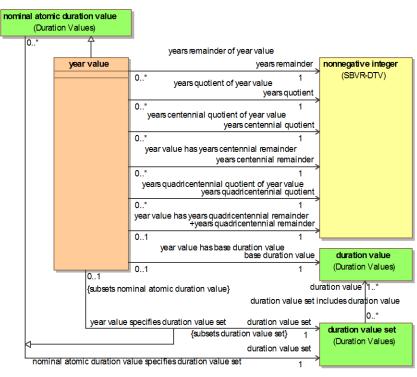

Figure 11.5 - Year Values

year value

Definition: nominal atomic duration value that has the time unit 'year'

years remainder

Concept Type: <u>role</u>

General Concept: nonnegative integer

years remainder of year value

Definition: the years remainder is the remainder produced by dividing the number of the year

<u>value</u> by <u>4</u>

Note: Each 4-year cycle includes exactly 1 leap day. Example: the <u>years remainder</u> of $^{\circ}5$ <u>years</u>' is 1

years quotient

Concept Type: role

General Concept: nonnegative integer

years quotient of year value

Definition: the <u>yearsquotient</u> is the quotient produced by dividing the <u>number</u> of the <u>year value</u> by

4

Note: Each 4-year cycle includes exactly 1 leap day. Example: the years quotient of '11 years' is 2

years centennial quotient

Concept Type: role

General Concept: nonnegative integer

years centennial quotient of year value

Definition: the years centennial quotient is the quotient produced by dividing the number of the

<u>year value</u> by <u>100</u>

Note: According to [Inter Gravissimas], a leap day is omitted for each <u>centennial year</u> that is not

a <u>quadricentennial year</u>.

Example: the <u>years centennial quotient</u> of ' $\underline{5}$ <u>years</u>' is $\underline{0}$ Example: the <u>years centennial quotient</u> of ' $\underline{301}$ <u>years</u>' is $\underline{3}$

years centennial remainder

Concept Type: role

General Concept: <u>nonnegative integer</u>

year value has years centennial remainder

Definition: the <u>years centennial remainder</u> is the remainder produced by dividing the number of the

year value by 100

Example: the <u>years centennial remainder</u> of <u>601 years</u> is <u>1</u>

years quadricentennial remainder

Concept Type: role

General Concept: <u>nonnegative integer</u>

year value has years quadricentennial remainder

Definition: the yearsquadricentennial remainder is the remainder produced by dividing the number

of the <u>year value</u> by 400

Example: the <u>years quadricentennial remainder</u> of <u>601 years</u> is <u>201</u>

years quadricentennial quotient

Concept Type: role

General Concept: nonnegative integer

years quadricentennial quotient of year value

Definition: the yearsquadricentennial quotient is the quotient produced by dividing the number of

the year value by 400

Note: According to [Inter Gravissimas], a leap day is included for each <u>quadricentennial year</u>

even though it is a centennial year.

Example: the <u>years quadricentennial quotient</u> of ' $\frac{301 \text{ years}}{\text{is } 0}$ is $\frac{0}{\text{Example}}$: the <u>years quadricentennial quotient</u> of ' $\frac{401 \text{ years}}{\text{is } 1}$ ' is $\frac{1}{1}$

base duration value

Concept Type: role

General Concept: <u>duration value</u>

year value has base duration value

Definition: the base duration value is the number of the year value times 365 days plus 1 day times

(the <u>years quotient</u> of the <u>year value</u> – the <u>years centennial quotient</u> of the <u>year</u>

<u>value</u> + the <u>years quadricentennial quotient</u> of the <u>year value</u>).

Note: That is, if Y is the year value, the base duration value B(Y) is given by:

B(Y) = Y * 365 + Y/4 - Y/100 + Y/400 days,

where the / denotes the quotient of the integer division.

Note: [Inter Gravissima] specifies that a leap day occurs every 4 years, except every 100 years,

with a further exception that a leap day does occur every 400 years.

Note: The base duration value is the number of days in a number of years that does not involve

two conditions:

- the year value is not a multiple of 4 and the particular calendar years involved include one

more leap year; or

- the year value is not a multiple of 100 and the particular calendar years involved include

one more centennial year (which may be a quadricentennial year)

Example: The base duration value of 400 years is $146\ 000 + 100 - 4 + 1 = 146\ 097$ days, and neither of the two conditions can apply. 400 years is actually a precise duration value.

The base duration value of 111 years is 40515 + 27 - 1 + 0 = 40541, but it is possible that

either of the two conditions above is met.

years duration value set

Example:

Concept Type: role

Definition: <u>duration value set</u>

year value specifies years duration value set

General Concept: nominal atomic duration value specifies duration value set

Definition: the <u>years duration value set</u> is the <u>duration value set</u> that consists of the following

duration values

- the base duration value of the year value,

- the base duration value of the year value minus 1 day, only if the years centennial

remainder of the year value is greater than zero,

- the <u>base duration value</u> of the <u>year value</u> plus <u>1 day</u>, only if the <u>years remainder</u> of the <u>year value</u> is greater than zero or the <u>years quadricentennial remainder</u> of the <u>year</u> value is greater than zero.

value is greater than zero,

Note: If Y is the year value, and B(Y) is the base duration value, the duration set specified by Y is

given by: $S(Y) = \{B(Y)\}$

 $\cup \{B(Y) - 1\}$, if Y mod 100 > 0,

 $\,\cup\,\,\{\,B(Y)+1\,\},\,if\,Y\,\,mod\,\,4>0\,\,or\,\,Y\,\,mod\,\,400>0.$

where 'mod' denotes the remainder of the integer division.

Note: The duration value set includes only the base duration value when the year value is exactly

divisible by 400 (none of the remainders is greater than zero).

Example: The duration value set for 400 years is {146 097 days}.

 $Example: \qquad \qquad The \ duration \ value \ set \ for \ 111 \ years \ is \ \{40\ 541\ days, \ 40\ 540\ days, \ 40\ 542\ days\}.$

Example: For example, the 111 years could be between 1903 and 2014, which includes the 27 leap years between 1903 and 2011 (including the quadricentennial year 2000), but also the leap year in 2012. So the actual value is 40 542. By comparison, the 111 years between July

1,1796 and July 1, 1907 includes two centennial years and thus only 25 leap years, so the actual value is 40 540.

Example: The duration value set for 100 years is {36 524 days, 36 525 days}. For example, the 100

years from 1814 and 1914 is 36 524 days. The 100 years from 1914 to 2014 is 36 525 days.

11.6 Gregorian Month Values

This sub clause defines the meaning of nominal atomic duration values that use the nominal time unit month.' It accounts for the varying numbers of calendar days in the calendar months of the Gregorian calendar. It accounts for leap years by considering that 48 months (4 years of 12 months) includes one leap day (February 29). The computation adjusts for the fact that centennial years have no leap days, but quadricentennial years have one leap day.

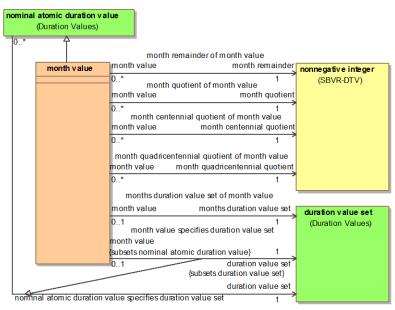

Figure 11.6 - Month Values

Commented [EB93]: ty po

Formatted: term

Note: this sub clause defines some concepts, such as 'month remainder', that are only needed to support the concept 'month value specifies duration value set'. These supporting concepts need not be explicitly defined in versions of this specification in other modeling systems.

month value

Definition: nominal atomic duration value that has the time unit 'month'

months remainder

Concept Type: role

General Concept: nonnegative integer

months remainder of month value

Definition: the months remainder is the remainder produced by dividing the number of the month

Note: 48 is the number of months in a 4-year cycle that includes one leap day.

the months remainder of '50 months' is 2 Example:

months quotient

Concept Type: role

General Concept: nonnegative integer

months quotient of month value

Definition: the months quotient is the quotient produced by dividing the number of the month value

Note: 48 is the number of months in a 4-year cycle that includes one leap day.

Example: the months quotient of '50 months' is 1

months centennial quotient

Concept Type:

General Concept: nonnegative integer

months centennial quotient of month value

Definition: the months centennial quotient is the remainder produced by dividing the number of

the month value by 1 200 1 200 is 100 years of 12 months. According to [Inter Gravissimas], a leap day is omitted for Note:

each centennial year that is not a quadricentennial year.

Example: the months centennial quotient of '60 months' is 0 Example: the months centennial quotient of '2405 months' is 2

months quadricentennial quotient

Concept Type:

General Concept: nonnegative integer

months quadricentennial quotient of year value

the months quadricentennial quotient is the remainder produced by dividing the number Definition:

of the month value by 4800

4800 is 400 years of 12 months. According to [Inter Gravissimas], a leap day is included for Note:

each quadricentennial year even though it is a centennial year.

Example: the months quadricentennial quotient of '10 months' is $\underline{0}$ Example: the months quadricentennial quotient of ' $\underline{4805}$ months' is $\underline{1}$

months duration value set

Concept Type: role

Definition: <u>duration value set</u>

months duration value set of month value

Definition: the months duration value set is specified by the following table, according to the

months remainder of the month value

11.7 Gregorian Time Coordinates

This sub clause defines several Gregorian $\underline{\text{time coordinates}}$ and their meaning in terms of $\underline{\text{time scales}}$. It also "anchors" the Gregorian calendar on the $\underline{\text{Time Axis}}$ per the signing of the $\underline{\underline{\text{Conventiondu Mètre}}}$.

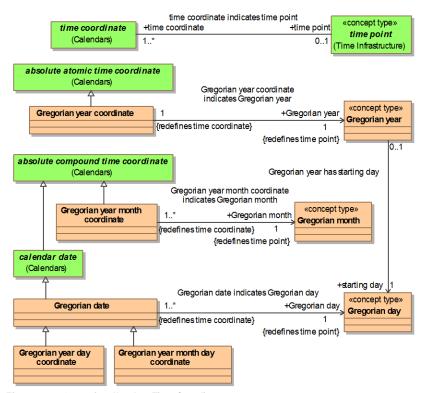

Figure 11.7 - Gregorian Absolute Time Coordinates

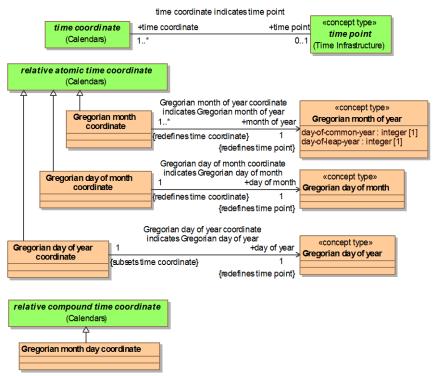

Figure 11.8 - Gregorian Relative Time Coordinates

- A Gregorian year coordinate indicates a Gregorian year, for example "2010"
- A Gregorian month coordinate indicates a Gregorian month, for example "January"
- A Gregorian day of year coordinate indicates a Gregorian day of year, for example "Gregorian day of year 360"
- A <u>Gregorian day of month coordinate</u> indicates a <u>Gregorian day of month</u>, for example "Gregorian day of month 14"
- A <u>Gregorian year month coordinate</u> <u>combines</u> a <u>Gregorian year</u> and a <u>Gregorian month of year</u>, <u>to indicate</u> a <u>Gregorian month</u>, for example "<u>July 2010</u>"
- A <u>Gregorian year month day coordinate combines a Gregorian year</u>, a <u>Gregorian month of year</u>, and a <u>Gregorian day of month to indicate a Gregorian day</u>, for example "9 July 2010"
- A <u>Gregorian year day coordinate</u> combines a <u>Gregorian year</u> and a <u>Gregorian day of year</u> to indicate a <u>Gregorian day</u>, for example "2010 day 33"
- A <u>Gregorian month day coordinate</u> <u>combines</u> a <u>Gregorian month of year</u> and a <u>Gregorian day of month to refer to one time interval</u> in each Gregorian year, for example "<u>9 July</u>", but only the first 60 of them (January 1 to February 29) indicate Gregorian day of year time points

Gregorian year coordinate

Definition: <u>absolute atomic time coordinate</u> that indicates a <u>Gregorian year</u>

Necessity: Each Gregorian year coordinate indicates a Gregorian year that has an index equal

to the index of the Gregorian year coordinate

Description: A Gregorian year coordinate directly gives the Gregorian year number.

Example: 2010

Gregorian month coordinate

Definition: relative atomic time coordinate that indicates a Gregorian month of year

Necessity: Each Gregorian month coordinate indicates a Gregorian month of year that has an

index equal to the index of the Gregorian month coordinate.

Description: A <u>Gregorian month coordinate</u> directly gives the <u>index</u> of a <u>calendar month</u> within a

calendar year.

Necessity: Each Gregorian month coordinate is greater than or equal to 1.

Necessity: Each Gregorian month coordinate is less than or equal to 12.

Example: "January" and "month 1" indicate the same Gregorian month of year

Gregorian day of year coordinate

Definition: relative atomic time coordinate that indicates a Gregorian day of year

Necessity: Each Gregorian day of year coordinate indicates a Gregorian day of year that has

an index equal to the index of the Gregorian day of year coordinate.

Description: A Gregorian day of year coordinate directly gives the index of a calendar day within a

calendar year.

Necessity: Each Gregorian day of year coordinate is greater than or equal to 1.

Necessity: Each Gregorian day of year coordinate is less than or equal to 366.

Example: "day 45" and "14 February" indicate the same Gregorian day of year

Gregorian day of month coordinate

Definition: relative atomic time coordinate that indicates a Gregorian day of month

Necessity: Each Gregorian day of month coordinate indicates a Gregorian day of month that has an index equal to the index of the Gregorian day of month coordinate.

Description: A Gregorian day of month coordinate directly gives the index of a calendar day within

a <u>calendar month</u>.

Necessity: Each Gregorian day of month coordinate is greater than or equal to 1.

Necessity: Each Gregorian day of month coordinate is less than or equal to 31.

Example: "Gregorian day of month 14" indicates the Gregorian day of month that has index 14

These <u>absolute compound time coordinates</u> support various combinations of <u>Gregorian years</u>, <u>Gregorian months of year</u>, and <u>calendar days</u>.

Gregorian year month coordinate

Definition: absolute compound time coordinate that combines a Gregorian year coordinate and

that combines a Gregorian month coordinate and that indicates a Gregorian month

Necessity: Each Gregorian year month coordinate indicates a Gregorian month that has index

12 times (the index of the Gregorian year coordinate minus 1) plus (the index of the

Gregorian month coordinate minus 1).

Description: The <u>Gregorian year coordinate and the Gregorian month coordinate of the</u>

Gregorian year month coordinate jointly identify the Gregorian month on the infinite

Gregorian months scale.

Note: <u>The definition subtracts 1 from the indices of the Gregorian year coordinate and</u>

 $\underline{Gregorian\,month\,coordinate\,because\,these\,are\,index\,origin\,value\,\underline{1}.}$

Example: "2010 month 3" combines the set of (2010, month 3), and indicates the Gregorian month

that has index 24123

Deleted: month of years

Commented [EB94]: ty po

starting day

Note:

Concept Type: role

Definition: Gregorian day that is the first calendar day of some Gregorian year

Gregorian year has starting day

the starting day is the Gregorian day that corresponds to the time interval that is Definition:

part of the Gregorian year and that is an instance of day-of-year 1

Each Gregorian year has exactly one starting day. Necessity:

The index of the starting day of each Gregorian year that follows Gregorian year Necessity:

1600 equals 584 391

plus 365 times (index of the Gregorian year minus 1601) plus ((index of the Gregorian year minus 1601) divided by 4) minus ((index of the Gregorian year minus 1601) divided by 100) plus ((index of the Gregorian year minus 1601) divided by 400).

The index of each Gregorian year is greater than 1581 Necessity:

Note: The Gregorian calendar was adopted in different places at different times between 1582 and

1918. The formula is only valid for Gregorian dates.

In mathematical form, the definition above is:

sd = 584391 + (365 * y) + (y/4) - (y/100) + (y/400)

sd is the index of the starting day y is the index of a Gregorian year $-\frac{1601}{}$

y >= zero

/ is integer division

584 391 is the index of 1 January 1601, computed as 577 738 (index of 15 October 1582) Note:

plus 6653 days from 15 October 1582 through 1 January 1601.

Note: 1 January 1601 is used as the basis for this formula because the pattern of leap days is

> consistent since 1601. It is the first day after the first quadricentennial year after [Inter Gravissimas]. This day is picked because the first day of a Gregorian year does not include

any leap day that occurs during that Gregorian year.

The definition compensates for leap days by adding 1 for each 4th year, subtracting 1 for Note:

each 100th year (because most centurial years are not leap years), and adding 1 for each 400th year (because quadricentennial years are leap years), per [Inter Gravissimas].

Note: This formula is valid only for <u>Gregorian calendar years</u> after <u>1600</u>.

The first calendar day of 2010 is Gregorian day 733775 Example:

day-of-common-year

Concept Type: <u>role</u>

General Concept: nonnegative integer

Definition: the number of days between the beginning of a Gregorian year and the beginning of a given

Gregorian month of year in a common year

Gregorian month of year has day-of-common-year

Definition: the day-of-common-year is the number of days between the beginning of a common

year and the instance of the Gregorian month of year that is part of the common

The day-of-common-year for each Gregorian month-of-year is given in Table 11.1. Note: Example:

The day-of-common-year for April is 90 (days). The duration of the time period from January to April in a common year is 31 days (of January) + 28 days (of February) + 31

days (of March).

day-of-leap-year

Concept Type: role

General Concept: nonnegative integer

Definition: the number of days between the beginning of a Gregorian year and the beginning of a given

Gregorian month of year in a leap year

Gregorian month of year has day-of-leap-year

Definition: the day-of-leap-year is the number of days between the beginning of a leap year and the

instance of the Gregorian month of year that is part of the leap year

Note: The day-of-leap-year for each Gregorian month-of-year is given in Table 11.1.

Example: The <u>day-of-leap-year</u> for April is 91. The duration of the time period from January to

April in a leap year is 31 days (of January) + 29 days (of February) + 31 days (of March).

Gregorian year month day coordinate

Definition: Gregorian date that combines a Gregorian year coordinate and that combines a

Gregorian month coordinate and that combines a Gregorian day of month

coordinate, and that indicates a Gregorian day

Necessity: Each Gregorian year month day coordinate indicates the Gregorian day that equals

the starting day of the Gregorian year that is indicated by the Gregorian year coordinate, plus the value taken for the start of each month from the table of calendar days (below) as indexed by the index of the Gregorian month coordinate and whether the Gregorian year coordinate indicates a leap year, plus the index of the Gregorian day of

month coordinate minus 2.

Description: The index of the <u>Gregorian day</u> on the <u>Gregorian days scale</u> is computed from the three

components of the $\underline{\text{Gregorian year coordinate}}.$

Example: "2010 month 3 day 15" combines the set of (2010, month 3, day 15), and indicates the

Gregorian day that has index 733848. The index is 149 457 calendar days after January 1, 1601, which has index 584 391 (the reference point for the formula).

The 149 457 days is calculated as:

365*(2010 - 1601) + (2010 - 1601)/4 - (2010-1601)/100 + (2010 - 1601)/400

(number of calendar days from Jan 1, 1601 to Jan 1, 2010)

plus 59 (to day 1 of month 3, from the table) plus 14 (from day 1 to day 15).

Table 11.1 - Index of the First Gregorian Day of Year of Fach Gregorian Month of Year

The table shown above is derived from Table 1 of [ISO 8601].

Gregorian year day coordinate

Description:

Definition: Gregorian date that combines a Gregorian year coordinate and that combines a

Gregorian day of year coordinate and that indicates a Gregorian day

Each Gregorian day year coordinate indicates a Gregorian day that equals the index Necessity:

of the starting day of the Gregorian year that is indicated by the Gregorian year

coordinate, plus the index of the Gregorian day of year coordinate minus 1. A Gregorian day year coordinate combines a Gregorian year coordinate and a

Gregorian day of year coordinate to identify a particular Gregorian day.

Example:

"2010 day 45" combines the set of (2010, day 45), and indicates the Gregorian day that has index 733819. The index is 149 428 calendar days after January 1, 1601, which has index 584 391 (the reference point for the formula). The 149428 days is calculated as: 365*(2010-1601)+(2010-1601)/4-(2010-1601)/100+(2010-1601)/400

(number of calendar days from Jan 1, 1601 to Jan 1, 2010) plus 44 (from day 1 to day 45).

Gregorian month day coordinate

Definition: relative compound time coordinate that combines a Gregorian month coordinate

and a Gregorian day of month coordinate, and that refers to one instance of

Gregorian day in a given Gregorian year

Necessity: Each Gregorian month day coordinate converts to the time set {Gregorian day of

year from the start of the <u>calendar year</u> to the <u>calendar month</u> that has the <u>index</u> of the <u>Gregorian month coordinate</u> in common years, <u>Gregorian day of year</u> from the start of the <u>calendar year</u> to the <u>calendar month</u> that has the <u>index</u> of the <u>Gregorian month</u> coordinate in leap years } plus the index of the <u>Gregorian day of month coordinate</u>

minus 1 day

Note: A Gregorian month day coordinate does not include a year number, so there is no way to

know whether a <u>March</u> date follows a 28-day or 29-day <u>February</u>. For this reason, every <u>Gregorian month coordinate</u> after <u>February 28</u> does not consistently *indicate* either of two possible <u>Gregorian days of year</u>. But it *converts to* the time set that includes both of

them.

Example: "15 June" combines "June" and "(Gregorian day of month) 15". It refers to one calendar

day in each Gregorian year, but in common years it is <u>Gregorian day of year 165</u> and in leap years it is <u>Gregorian day of year 166</u>. So, "15 June" <u>converts to the time set</u> { <u>Gregorian day of year 166</u>.

year 165, Gregorian day of year 166}

Example: "15 January" combines "January" and "(Gregorian day of month) 15". It always indicates

Gregorian day of year 15.

Gregorian date

Synonym: <u>Gregorian date coordinate</u>

Definition: <u>calendar date</u> that indicates a <u>Gregorian day</u>

Dictionary Basis: ISO 8601 (2.1.9, 'calendar date')

Note: <u>Gregorian date coordinates</u> may be combined with <u>time offsets</u>, see clause 10.3.

Example: $\frac{1989 \text{ September 3}}{2005 \text{ day } 49}$

11.8 Gregorian Indefinite Scale Comparisons and Conversions

These verb concepts enable comparison of <u>time points</u> that are on different <u>indefinite time scales</u>. These are <u>absolute time points</u>, meaning that each <u>corresponds to exactly one time interval</u>.

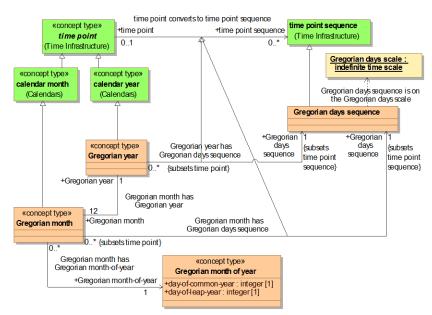

Figure 11.9 - Gregorian Year Conversions

The following Necessities identify the Gregorian calendar time points that can be converted to a common 'shared' time scale. Conversions to other time scales, such as International Atomic Time, are possible.

Each <u>Gregorian year</u> shares the <u>Gregorian days scale</u> with each <u>Gregorian month</u>. Necessity:

1979 shares the Gregorian days scale with June 1990 Example:

Necessity: Each Gregorian year shares the Gregorian days scale with each Gregorian day.

1949 shares the Gregorian days scale with 23 June 1990 Example:

Necessity: Each Gregorian month shares the Gregorian days scale with each Gregorian day.

June 1990 shares the Gregorian days scale with 23 June 1990 Example:

Conversions to other time scales, such as International Atomic Time, are possible.

The following concepts relate Gregorian years to the Gregorian days scale.

Gregorian days sequence

Definition: time point sequence that is on the Gregorian days scale

Gregorian year has Gregorian days sequence

General Concept: time point converts to time point sequence

Definition: the Gregorian year converts to the Gregorian days sequence

Each Gregorian year converts to exactly one Gregorian days sequence. Necessity: Necessity:

The first time point of the Gregorian days sequence of a Gregorian year is the

starting day of the Gregorian year.

The <u>Gregorian days sequence</u> of a <u>Gregorian year</u> has <u>cardinality</u> 365 if the <u>Gregorian</u> Necessity:

year is a common year, and has cardinality 366 if the Gregorian year is a leap year.

The Gregorian year converts to the time point sequence whose first time point is the first Note:

Gregorian day of the year (the starting day) and that has as many Gregorian day time

Commented [EB95]: reformat Glossary Item Heading

Formatted: Level 5, No bullets or numbering

points as the year has days. The last time point will be the starting day plus length of year

minus 1.

Example: The Gregorian year that is indicated by "2010" converts to Gregorian day 733 775

through Gregorian day 734 140.

The following concepts support conversion of <u>Gregorian months</u> to the <u>Gregorian days scale</u>. Note that the first two concepts associate the Gregorian month with "month-of-year" and "year" time points, and thus with common time coordinates.

Gregorian month has Gregorian year

Definition: the <u>Gregorian month</u> is part of the <u>Gregorian year</u>
Necessity: Each <u>Gregorian month</u> has exactly one <u>Gregorian year</u>.

Necessity: The index of the Gregorian year of a Gregorian month equals 1 plus the integer

quotient of dividing the index of the Gregorian month by 12.

Example: <u>Gregorian month 24108</u> has <u>Gregorian year 2010</u>

Gregorian month has Gregorian month of year

Definition: the Gregorian month of year corresponds to the time interval that is the instance of

the Gregorian month

Necessity: Each Gregorian month has exactly one Gregorian month of year.

Necessity: The index of the Gregorian month-of-year of a Gregorian month equals 1 plus the

integer remainder of dividing the <u>index</u> of the <u>Gregorian month</u> by <u>12</u>

Example: Gregorian month 24108 has Gregorian month of year 1, i.e., January.

Gregorian month has Gregorian days sequence

General Concept: <u>time point converts to time point sequence</u>

Definition: the Gregorian month converts to the Gregorian days sequence
Necessity: Each Gregorian month has exactly one Gregorian days sequence.

Necessity: The <u>duration</u> of the <u>Gregorian days sequence</u> of a <u>Gregorian month</u> is equal to the

<u>duration</u> of the <u>time period</u> that is the <u>instance</u> of the <u>Gregorian month</u>.

Necessity: The <u>index</u> of the <u>first time point</u> of the <u>Gregorian days sequence</u> of a <u>Gregorian</u>

month is equal to the index of the starting day of the Gregorian year of the Gregorian month minus 1 plus the day-of-common-year of the Gregorian month-of-year of the Gregorian month if the Gregorian year is a common year, or the day-of-leap-year of

the <u>Gregorian month-of-year</u> if the <u>Gregorian year</u> is a <u>leap year</u>.

Description: the <u>Gregorian month converts to a sequence of Gregorian days</u> on the indefinite

<u>Gregorian days scale</u>, using the <u>starting day</u> of the <u>Gregorian year</u> of the <u>Gregorian month</u> and the <u>day-of-common-year</u> or <u>day-of-leap-year</u> of the <u>Gregorian month-of-</u>

year of the Gregorian month.

Note: The <u>day-of-common-year</u> and the <u>day-of-leap-year</u> for a <u>Gregorian month-of-year</u> are

given in Table 11.1

The Gregorian month that is indicated by "June 2010" converts to Gregorian day 733 926 through Gregorian day 733 955 on the Gregorian days scale. The starting day of 2010 has index 733775, the day of common year of June is 152, and 2010 is a

common year.

11.9 Gregorian Month of Year Comparisons and Conversions

These verb concepts enable comparison of $\underline{\text{time points}}$ that are on the $\underline{\text{Gregorian year of days scale}}$ and the $\underline{\text{Gregorian year of months scale}}$.

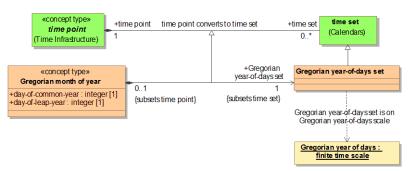

Figure 11.10 - Gregorian Month of Year Conversion

The following Necessity identifies the fact that <u>Gregorian months of year</u> and <u>Gregorian days of year</u> can be compared by conversion of the former to the <u>Gregorian year of days scale</u>:

Necessity: Each <u>Gregorian month of year shares the Gregorian year of days scale</u> with each

Gregorian day of year.

Example: "May" can be compared with "day 33" on the Gregorian year of days scale

Because of leap days, a <u>Gregorian month of year converts to</u> a <u>time set</u> on the <u>Gregorian year of days scale</u>, rather than to an individual <u>time point sequence</u>. The following concepts characterize these conversions.

Gregorian year of days set

Definition: <u>time set on the Gregorian year of days scale</u>

Gregorian month of year has Gregorian year of days set

General Concept: time point converts to time set

Definition: the Gregorian month of year converts to the Gregorian year of days set

 Necessity:
 Each Gregorian month of year converts to exactly one Gregorian year of days set.

 Necessity:
 Each Gregorian month of year converts to the time set on the Gregorian year of days

scale that is given for the Gregorian month of year in Table 11.2.

Note: The time set for January has only one member. All of the others have one time point

sequence for common years and one time point sequence for leap years.

These time sets could be formulated "intensionally" in much the same way as the

Note: These time sets could be formulated "intensionally" in much the same way as the Gregorian day time point sequences are formulated for Gregorian months, but since

there are only 12, it is simpler to enumerate the extension of the verb concept.

Example: The Gregorian month of year that is indicated by 'August' converts to the time set

{ <u>Gregorianday of year 213</u> <u>through Gregorianday of year 243</u>, <u>Gregorianday of year 214</u> <u>through Gregorianday of year 244</u>}

Commented [EB96]: Reformat Glossary Item Heading

Formatted: Level 5, No bullets or numbering

3	<u>March</u>	(Gregorian day of year 60 through Gregorian day of year 90, Gregorian day of year 61 through Gregorian day of year 91)
4	<u>April</u>	(Gregorian day of year 91 through Gregorian day of year 120, Gregorian day of year 92 through Gregorian day of year 121)
<u>5</u>	Mav	(Gregorian day of year 121 through Gregorian day of year 151, Gregorian day of year 122 through Gregorian day of year 152)
<u>6</u>	June	(Gregorian day of year 152 through Gregorian day of year 181, Gregorian day of year 153 through Gregorian day of year 182)
Z	July	(Gregorian day of year 182 through Gregorian day of year 212, Gregorian day of year 183 through Gregorian day of year 213)
<u>8</u>	August	(Gregorian day of year 213 through Gregorian day of year 243, Gregorian day of year 214 through Gregorian day of year 244)
9	September	(Gregorian day of year 244 through Gregorian day of year 273, Gregorian day of year 245 through Gregorian day of year 274)
10	October	(Gregorian day of year 274 through Gregorian day of year 304, Gregorian day of year 275 through Gregorian day of year 305)
11	<u>November</u>	{Gregorian day of year 305 through Gregorian day of year 334, Gregorian day of year 306 through Gregorian day of year 335}
12	December	(Gregorian day of year 335 through Gregorian day of year 365, Gregorian day of year 336 through Gregorian day of year 366)

The table shown above is derived from Table 1 of [ISO 8601].

12 ISO Week Calendar (normative)

12.1 General

The week calendar has been used for centuries, separate from and in combination with the <u>Gregorian calendar</u>, even though they are incommensurate. This <u>calendar</u> supports human discourse using weekday names such as "<u>Monday</u>", "<u>Tuesday</u>", and so forth.

This specification follows [ISO 8601] in defining "Monday" as the first day of the week. Various cultures and religions define other initial week days. Users of this specification are welcome to redefine the weekday concepts according to their preferences.

We define January 3, 2000 to be a Monday, and thereby define an indefinite sequence of time intervals that are <u>ISO</u> weeks. That is the basis for the <u>ISO weeks time scale</u>.

These ISO weeks are further gathered into ISO week-based years – time periods of exactly 52 or 53 ISO weeks that correspond roughly to Gregorian years. (The correspondence algorithm is given in ISO 8601. It is based on the 'first Thursday rule' – the first week of an ISO week-based year is the ISO week that contains the first Thursday in the Gregorian year, and it may contain days from the prior Gregorian year.) The ISO week-based year forms the basis for the ISO year of week-based year forms the basis for the ISO year of week-based year. These scale then provide the basis for time coordinates of the ISO year-week form, such as "year 2000 week 6", and the ISO year-week-day form, such as "2004 week 37 day 2" or "Tuesday of 2004 week 37".

ISO Week Calendar Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Included Vocabulary: <u>Gregorian Calendar Vocabulary</u>

12.2 ISO Week Time Scales

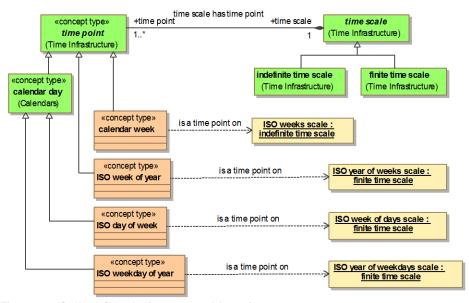

Figure 12.1 - ISO Week Calendar time scales and time points

ISO weeks scale

Definition: indefinite time scale that has granularity week and that has time points that are ISO

<u>weeks</u>

Necessity: The <u>index origin value</u> of the <u>ISO weeks scale</u> is <u>104304</u>.

Necessity: Calendar

Note: Gregorian day 730 124 is Monday, January 3, 2000. This date was chosen for consistency

with ISO 8601, which defines the origin of the ISO weeks calendar as Saturday, January 1, 2000, but that date is part of the last week of Gregorian year 1999 according to the

algorithm in ISO 8601.

Note: ISO week 104 303 ended on Gregorian day 730 123 and not 730 121 (a multiple of 7),

because Gregorian day 1 was a Saturday, and ISO week 1 began the following Monday (per

ISO 8601).

Note: A more convenient reference for the ISO weeks scale is that January 1, 1601 was the

Monday of calendar week 83 485.

ISO week of days scale

Definition: the finite time scale that has granularity 1 day and that has cardinality 7 and that

exactly subdivides ISO week

Necessity: Each ISO week subdivides into exactly 7 ISO days of week

Necessity: The index origin value of the ISO week of days scale equals 1.

Necessity: The first time point of the ISO week of days scale is the index origin member of the ISO.

week of days scale

Necessity: The index origin member of the ISO week of days scale is Monday.

Commented [EB97]: Issue 13-25 REPLACE text

Deleted: <#>Each |SO week | has] of |SO day of week |

ISO year of weeks scale

Definition: the finite time scale that has granularity 1 week and that has cardinality 53 and that

repeats over the ISO weeks scale

From [ISO 8601] clause 3.2.2: A calendar year has 52 or 53 weeks of year. Description:

The SO year of weeks scale repeats over the indefinite scale of ISO weeks and renumbers the Note:

weeks within a year from 1 to 52 or 53.

Necessity: The index origin value of the ISO year of weeks scale equals 1.

The first time point of the ISO year of weeks scale is the index origin member of the ISO Necessity:

Necessity: The first time point of the ISO year of weeks scale corresponds to each time interval that

is the instance of the starting week of a Gregorian year.

Note: From the definition of the starting week, it follows that the Thursday of a first ISO week

of year is one of the first 7 days of the year, but the Monday, Tuesday and Wednesday

might be part of the previous year.

Any Gregorian year that begins on Thursday, and any leap year that begins on Wednesday, Note:

has 53 ISO week of year time intervals. Any other year has 52 ISO week of year time

intervals.

ISO year of weekdays scale

Definition: the $\underline{\text{finite time scale}}$ that $\underline{\text{has granularity}}$ $\underline{\text{1 day}}$ and that $\underline{\text{has cardinality}}$ $\underline{\text{371}}$ and that

subdivides each ISO week-based year

The ISO year of weekdays scale subdivides the ISO week-based year in parallel to the way Note:

the Gregorian year of days subdivides the Gregorian year. But the two kinds of year are of

different lengths and are only loosely aligned.

Necessity: The index origin value of the ISO year of weekdays scale equals 1.

Necessity: The first time point of the ISO year of weekdays scale is the index origin member of the

ISO year of weekdays scale.

Necessity: Each instance of the first time point of the ISO year of weekdays is a Monday and is part

of the instance of the starting week of a Gregorian year.

Note: An instance of ISO weekday of year 1 may be as late as January 4 of the Gregorian year

or as early as December 29 of the previous Gregorian year.

ISO week

Note:

ISO 8601 (2.2.8, 'calendar week') Dictionary Basis:

Concept Type: concept type

<u>calendar week that is on the ISO weeks scale</u> and that corresponds to a time interval Definition:

that is started by a Monday The ISO weeks scale is an indefinite time scale; so each ISO week corresponds to exactly

one time interval.

This is an absolute time point because it is on an indefinite time scale. Note:

The third ISO week of 2009. Example:

ISO week-based year

time period that has duration 52 weeks or 53 weeks and that is started by an ISO week of year 1 and that meets an ISO week of year 1 Definition:

The ISO year of weeks scale subdivides each ISO week-based year. Necessity:

Each ISO week-based year is an instance of a time point sequence of ISO weeks. Necessity: Note: There is an indefinite sequence of ISO week-based years that covers the Time Axis in

parallel to the indefinite sequence of Gregorian years. But it was not necessary to model it. ISO week-based years are identified by Gregorian year numbers and the 'first Thursday

rule'.

Commented [EB98]: Issue ??? revise text

Formatted: name

Necessity: First Thursday Rule: The first Thursday in an ISO week-based year is the first

Thursday of a Gregorian year.

Each ISO week-based year is started by a time interval that is the 3 days preceding Necessity:

the first Thursday of a Gregorian year.

Note: The last Thursday of a Gregorian year is part of the last week of the corresponding ISO

week-based year. That determines whether the ISO week-based year has 52 weeks or 53

Note: Any Gregorian year that begins on Thursday, and any leap year that begins on Wednesday,

relates to an ISO week-based year that has 53 ISO week of year time intervals and 371 ISO weekday of year time intervals. The first ISO week of year includes 2 or 3 days from the prior year (from the Monday to the start of the year), and the 53rd ISO week of year includes 2 or 3 days from the following year (from the Thursday or Friday that is December 31st through the following Sunday). Any other year has 52 ISO week of year time intervals and 364 ISO weekday of year time intervals, but it may include 1 or 2 days of the prior year or 1

or 2 days from the following year, while losing 1 to 3 days to the other of them.

ISO day of week

Concept Type: concept type

Definition: calendar day that is on the ISO week of days scale

This is a relative time point because it is on a finite time scale. Note:

Necessity: ISO day of week1 is the concept 'Monday'. ISO day of week 2 is the concept 'Tuesday'. Necessity: Necessity: $\underline{ISO \text{ day of week} \underline{3}}$ is the concept 'Wednesday'. ISO day of week 4 is the concept 'Thursday'. Necessity: Necessity: ISO day of week 5 is the concept 'Friday'. Necessity: ISO day of week b is the concept 'Saturday'. ISO day of week 7 is the concept 'Sunday'. Necessity:

Source: ISO 8601 (Table 2)

Note: Other day of week time scales may choose a different numbering.

ISO week of year

Concept Type: concept type

Definition:

time point that is on the ISO year of weeks scale
Each ISO week of year renumbers at least 1 ISO week Necessity: This is a relative time point because it is on a finite time scale. Note:

ISO weekday of year

Concept Type: concept type

Definition: calendar day that is on the ISO year of weekdays scale Necessity: Each ISO weekday of year renumbers at least 1 Gregorian day.

Note Each ISO weekday of year time point is a calendar day of each ISO week-based year. The

usual time coordinate has "week and day" form, i.e., an ISO week of year coordinate and an

ISO day of week coordinate. See clause 18.

The following concepts were created to support the formal definition of the ISO year of weeks and ISO year of weekdays time scales.

Commented [EB99]: Issue 13-66 INSERT text

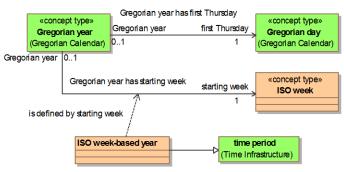

Figure 12.2 Starting week

first Thursday

Concept Type: role

General Concept: Gregorian day

Description: the <u>Gregorian day that</u> is the first <u>Thursday</u> in a <u>given Gregorian year</u>

Gregorian year has first Thursday

Definition: the first Thursday is the Gregorian day that corresponds to the time interval that is a

Thursday and that is part of the Gregorian year and that is not after a Thursday that

is part of the Gregorian year

Necessity: The <u>index</u> of the <u>first Thursday</u> of a <u>Gregorian year equals</u>

the index of the starting day of the Gregorian year plus 6

minus the remainder of dividing the index of the starting day of the Gregorian year by

<u>7</u>.

Note: If the remainder of dividing the index of the starting day by 7 is 0, the starting day is a

Friday, if the remainder is 1, it is a Saturday, and so on. So, 6 minus the remainder is the

number of days from the starting day to the first Thursday.

Note: This concept is introduced only to define the starting week concept.

starting week

Concept Type: role
General Concept: ISO week

Definition: the ISO week that includes the first Thursday of a given Gregorian year

Note: This definition follows the specifications in ISO 8601.

Note: It is possible that the Monday, Tuesday, and Wednesday of the starting week are part of

the previous Gregorian year. It is also possible that January 1^{st} , 2^{nd} , and 3^{rd} , are not part of

the starting week and are part of the last week of the previous year.

Example: January 1, 2000 is a Saturday. So the first Thursday of 2000 is January 6 and the starting

week of 2000 begins on Monday, January 3. Thus January 1, 2000 and January 2, 2000 are

part of the last week of 1999.

Example: January 1, 2002 is a Tuesday. So the first Thursday of 2002 is January 4, and the starting

week of 2002 begins on Monday, December 31, 2001.

Gregorian year has starting week

Definition: the starting week is the ISO week that includes the first Thursday of the Gregorian

<u>year</u>

Necessity: The index of the starting week of a Gregorian year equals the index of the starting day of the Gregorian year divided by 1/2 plus 1/2.

Note: This formula works because Gregorian day 1 was a Saturday. The quotient is the number of

complete weeks though a Friday that is on or before the starting day. So the quotient is greater by 1 exactly when January 1 falls on a Friday, Saturday, or Sunday, and the *following* Monday begins the starting week. Otherwise the starting week begins *on or before* the starting day, and there is one less complete week before it.

12.3 Days of the week

The concepts in this clause are the traditional days of the week, each of which is treated as a concept that corresponds to time intervals. They are defined to correspond to specific Gregorian days, by requiring that January 1, 2000 is a Saturday.

The days of the week are not 'time points' as defined. They become time points when they are chosen to be members of a time scale. This allows different time scales to make different choices for the first day of the week, without changing the relationship between the day of week and the actual time intervals.

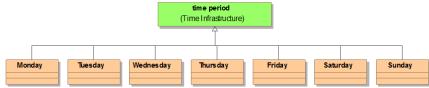

Figure 12.2 - Week days

Monday

Definition: <u>time interval</u> that has <u>duration 1 day</u> and that meets a <u>Tuesday</u>

Tuesday

Definition: <u>time interval</u> that has <u>duration</u> 1 day and that meets a <u>Wednesday</u>

Wednesday

Definition: <u>time interval</u> that has <u>duration 1 day</u> and that meets a <u>Thursday</u>

Thursday

Definition: <u>time interval that has duration 1 day and that meets a Friday</u>

Friday

Definition: <u>time interval</u> that has <u>duration 1 day</u> and that meets a <u>Saturday</u>

Saturday

Definition: <u>time interval that has duration 1 day and that meets a Sunday</u>

Necessity: One Saturday is the time interval that has duration 1 day and that starts Gregorian

<u>year 2000</u>.

Note: This requirement anchors the repeating sequence of days of week to specific Gregorian

days. It requires that January 1, 2000 is a Saturday. It follows that January 2, 2000 must be

the Sunday that it meets, and so on.

Sunday

Definition: <u>time interval that has duration 1 day and that meets a Monday</u>

12.4 Week Time Coordinates

This sub clause supports the following time coordinates based on weeks:

- An ISO day of week coordinate indicates an ISO day of week, for example "Tuesday"
- An ISO week of year coordinate indicates an ISO week of year, for example "week 15"
- An ISO week day coordinate combines an ISO week of year coordinate and an ISO day of week to indicate an ISO week day of year, for example "Tuesdayweek 15"
- An <u>ISO year week coordinate</u> combines a <u>Gregorian year</u> and an <u>ISO week of year coordinate</u> to indicate an <u>ISO week</u> for example "2010 week 15."
- An ISO year week day coordinate combines a Gregorian year, an ISO week of year coordinate, and an ISO day of week to indicate a calendar day, for example "Tuesday 2010 week 15."

The detailed definitions of these time coordinates follow.

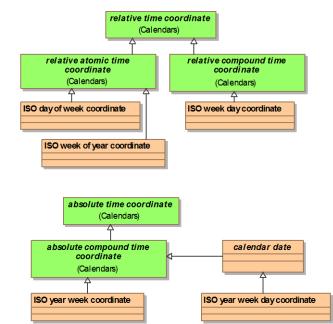

Figure 12.3 - Week Coordinates

ISO day of week coordinate

Definition: relative atomic time coordinate that indicates an ISO day of week

Necessity: Each ISO day of weekcoordinate indicates an ISO day of weekthat has the index

equal to the \underline{index} of the \underline{ISO} day of week coordinate

Description: An ISO day of week coordinate directly identifies an ISO day of week

 Necessity:
 Each ISO day of week coordinate is greater than or equal to 1.

 Necessity:
 Each ISO day of week coordinate is less than or equal to 1.

Example: Wednesday

ISO week of year coordinate

Synonym: ISO week number

Definition: relative atomic time coordinate that indicates an ISO week of year

Necessity: Each ISO week of year coordinate indicates the ISO week of year that has an index

equal to the index of the ISO week of year coordinate.

Description: A ISO week of year coordinate gives the number of an ISO week within a calendar

<u>year</u>.

Description: Number which identifies an ISO week within its calendar year according to the rule that

the first ISO week of a calendar year is that which includes the first Ihursday of that calendar year and that the last ISO week of a calendar year is the ISO week immediately preceding the first ISO week of the next calendar year. See [ISO 8086]

clause 2.2.10 for details.

Necessity: Each ISO week of year coordinate is greater than or equal to 1.

Necessity: Each ISO week of year coordinate is less than or equal to 53.

Example: week35

ISO week day coordinate

Definition: relative compound time coordinate that combines an ISO week of year coordinate

and that combines an ISO day of week coordinate and that indicates an ISO

weekday of year

Necessity: Each ISO weekday coordinate indicates the ISO weekday of year that has an

index equal to 7 times (the index of the ISO week of year coordinate - 1) plus the

index of the ISO day of week coordinate.

Description: An ISO week day coordinate combines an ISO week of year coordinate and an ISO

day of week coordinate to identify an ISO weekday of year, i.e., a calendar day within

an ISO week-based year.

Note: The first <u>ISO week of year</u> may start up to 3 days before the first <u>calendar day</u> of a

Gregorian year, and the last ISO week of year may include up to 3 calendar days from

the following $\underline{\text{Gregorian year}}$. See [ISO 8601] clause 3.2.2 for details.

Example: Wednesdayweek35 indicates ISO weekday of year 241
Example: Sundayweek1 indicates ISO weekday of year 7

ISO year week coordinate

Definition: <u>absolute compound time coordinate</u> that *combines* a <u>Gregorian year coordinate</u> and

that combines an ISO week of year coordinate, and that indicates an ISO calendar

<u>week</u>

Necessity: Each ISO year week coordinate indicates the ISO calendar week that has the index

that equals the index of the ISO week of year coordinate minus 1 plus the index of the starting week of the Gregorian year that is indicated by the Gregorian year

coordinate.

Description: An ISO year week coordinate identifies a calendar week time interval by the Gregorian

year in which it occurs and its relative position within the Gregorian year. Note that the

relationship between week of year 1 and January 1 is complex.

Example: 2010 week 35 indicates the ISO calendar week 104860. January 1, 2010 is a Friday. So

the starting week of 2010 begins on the following Monday, and is calendar week 104826.

Calendar week 104860 = 104826 + 35 - 1.

Formatted: Default Paragraph Font

ISO year week day coordinate

Definition: Gregorian date that combines a Gregorian year coordinate and that combines an

ISO week of year coordinate and that combines an ISO day of week coordinate

An ISO year week day coordinate indicates a calendar day by a combination of a Description:

Gregorian year coordinate, an ISO week of year coordinate, and a ISO day of week

Each ISO year weekday coordinate indicates the Gregorian day that has an index Necessity:

that equals 7 times the index of the ISO week of year coordinate of the ISO year

week day coordinate
plus the index of the ISO day of week coordinate of the ISO year week day

coordinate minus 11
plus the index of the first Thursday of the Gregorian year that is indicated by the

Gregorian year coordinate of the ISO year weekday coordinate.

Note: That is, the ISO year week day coordinate (y, w, d) indicates the Gregorian day whose

7*(w-1) + (d-1) + firstThursday(y) - 3, or

7 * w + d + firstThursday(y) - 11.

The beginning day of the starting week is the Monday before the first Thursday, so its

index is the index of the first Thursday minus 3.

 $\underline{\text{Wednesday 2010 week 35}} \text{ indicates } \underline{\text{Gregorian day 834647}} \text{ (starting weekday of } \underline{\text{2010}} \text{)} + \underline{\text{238}}$ Example:

 $(\underline{7} * (\underline{35} - \underline{1})) + \underline{3} - \underline{1} \square \underline{\text{Gregorian day } 834887}.$

13.3 **Time of Day Time Points**

midnight

Definition: second of day 0

time point 0 on the day of seconds time scale corresponds to time intervals that have Necessity:

duration 1 second and start an instance of a calendar day

noon

Definition: second of day 43 200

Note: 43 200 = 12 hours * 60 minutes * 60 seconds

hour of day

Dictionary Basis: ISO 8601 (3.2.3) Concept Type: concept type

Definition: time point that is on the day of hours scale where the index of the time point represents the

number of full hours that have elapsed since midnight at the start of each time interval that

the time point corresponds to

Necessity: Each time interval is an instance of hour of day 0 if and only if the time interval has

duration 1 hour and starts an instance of a calendar day.

Necessity: For each <u>hour of day</u>₁ that has an <u>index</u> that is greater than $\underline{0}$, each <u>time interval</u> is

an instance of hour of day 1 if and only if the time interval has duration 1 hour and is

Deleted: <#>Each calendar day has 86400 of second of day.¶

Deleted: <#>Each hour of day has 60 of 'minute of hour'.¶

Deleted: <#>Each minute of hour has 60 of second of minute . ¶

met by an instance of the hour of day that precedes hour of day 1 on the

<u>day of hours scale</u>.

The standard that the <u>hour of day</u> is counted since <u>midnight</u> was established by the Note:

International Meridian Conference of 1884 [International Meridian].

Note: This is a relative time point because it is on a finite time scale.

minute of day

Concept Type: concept type

Definition: time point that is on the day of minutes scale where the index of the time point represents

the number of full minutes that have elapsed since midnight at the start of each time interval

that the time point corresponds to

Necessity: Each time interval is an instance of minute of day 0 if and only if the time interval

has duration 1 minute and starts an instance of a calendar day.

Necessity: For each minute of day1 that has an index that is greater than 0, each time interval

is an instance of minute of day if and only if the time interval has duration 1 minute and is met by an instance of the minute of day that precedes minute of day on

the <u>day of minutes scale</u>.

This is a relative time point because it is on a finite time scale. Note:

Example: "03:15" is the minute-of-day that has index 195

second of day

Concept Type: concept type

Definition: time point that is on the day of seconds scale where the index of the time point represents

the number of full seconds that have elapsed since midnight at the start of each time

interval that the time point corresponds to

Necessity: Each time interval is an instance of second of day 0 if and only if the time interval

has duration 1 second and starts an instance of a calendar day.

Necessity: For each second of day1 that has an index that is greater than 0, each time interval

is an instance of second of day 1 if and only if the time interval has duration 1 second and is met by an instance of the second of day that precedes second of

day₁ on the day of seconds scale.

Note: This is a relative time point because it is on a finite time scale. Example:

"<u>03:15:48</u>" is the <u>second-of-day</u> that has <u>index</u> <u>11748</u>

leap second

Concept Type: concept type

Definition: second of day that is used to adjust UTC to ensure appropriate agreement with the rotation

of the Earth

ISO 8601 (2.2.2, 'leap second') Dictionary Basis:

Leap seconds are added or deleted at 23:59:59 on specific calendar days of UTC. These Note:

intercalary seconds of day adjust midnight of the next calendar day to match Earth's rotation. The International Earth Rotation and Reference Systems Service [IERS] announces leap seconds whenever the difference between UTC and the Earth's rotation exceeds 0.6

seconds.

Note: As of 2012, there is a proposal to drop the 'leap second' concept. This proposal will be

formally considered at the World Radio Conference in 2015.

minute of hour

Dictionary Basis: ISO 8601 (3.2.3) Concept Type: concept type

Definition: time point that is on the hour of minutes scale where the index of the time point represents

the number of full minutes that have elapsed since the last full hour at the start of each time

interval that the time point corresponds to

Each $\underline{\mathsf{time}}\,\mathsf{interval}\,\mathsf{is}\,\mathsf{an}\,\underline{\mathsf{instance}}\,\mathsf{of}\,\underline{\mathsf{minute}}\,\mathsf{of}\,\mathsf{hour}\,\mathsf{0}\,\mathsf{if}\,\mathsf{and}\,\mathsf{only}\,\mathsf{if}\,\mathsf{the}\,\underline{\mathsf{time}}\,\mathsf{interval}$ Necessity:

has duration 1 minute and starts an instance of an hour of day.

Necessity: For each minute of hour₁ that has an index that is greater than 0, each time

interval is an instance of minute of hour, if and only if the time interval has duration 1 minute and is met by an instance of the minute of hour that precedes

minute of hour on the hour of minutes scale

This is a relative time point because it is on a finite time scale. Note:

second of minute

Dictionary Basis: ISO 8601 (3.2.3) Concept Type: concept type

Definition:

time point that is on the minute of seconds scale where the index of the time point represents the number of full seconds that have elapsed since the last full minute at the start

of each time interval that the time point corresponds to

Necessity: Each time interval is an instance of second of minute 0 if and only if the time interval

has duration 1 second and starts an instance of a minute of day.

Necessity: For each second of minute₁ that has an index that is greater than 0, each time

interval is an instance of second of minute 1 if and only if the time interval has duration 1 second and is met by an instance of the second of minute2 that precedes

second of minute₁ on the minute of seconds scale.

This is a relative time point because it is on a finite time scale. Note:

Note: Business Calendar Concepts

hour period

Definition: time period that begins and ends at the same minute of hour on consecutive hours of day

1:05 to 2:05 Example:

13.4 Time of Day Time Coordinates

This sub clause defines the following relative time coordinates and time scales for these combinations of time of day time units:

- An hour coordinate indicates an hour of day, for example "hour 10" or "10 a.m."
- A minute coordinate indicates a minute of hour, for example "minute 33"
- A second coordinate indicates a second of minute, for example "second 27"
- · An hour minute coordinate combines an hour of day and a minute of hour, to indicate a minute of day, for example "10:33"
- · An hour minute second coordinate combines an hour of day, a minute of hour, and a second of minute, to indicate a second of day, for example "10:33:27"

This specification does not define time coordinates and time scales for fractions of seconds (e.g., milliseconds). Business vocabularies may extend this specification as needed to address fractional seconds.

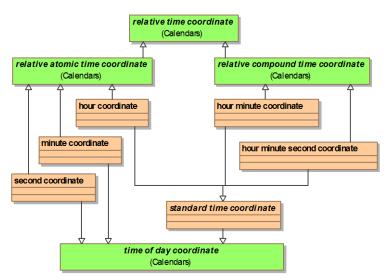

Figure 13.2 - Time of Day Coordinates

hour coordinate

Definition: relative atomic time coordinate that indicates an hour of day

Necessity: Each hour coordinate indicates an hour of day that has the index equal to the index

of the hour coordinate.

Description: An hour coordinate directly indicates an hour of day.

Necessity: Each hour coordinate is greater than or equal to 0.

Necessity: Each hour coordinate is less than or equal to 23.

Example: "11p.m." and "23:00" indicate the same hour of day

minute coordinate

Definition: relative atomic time coordinate that indicates a minute of hour

Necessity: Each minute coordinate indicates a minute-of-hour that has the index equal to the

index of the minute coordinate.

 $\begin{array}{lll} \text{Description:} & \text{A} \ \underline{\text{minute coordinate}} \ \underline{\text{directly } indicates} \ \underline{\text{a} \ \underline{\text{minute of hour.}}} \\ \text{Necessity:} & \underline{\text{Each } \underline{\text{minute coordinate}}} \ is \ \underline{\text{greater than or equal to } \underline{0}}. \\ \text{Necessity:} & \underline{\text{Each } \underline{\text{minute coordinate}}} \ is \ \underline{\text{less than or equal to } \underline{59}}. \\ \end{array}$

Example: minute 23

Note: This type of time coordinate is not common in everyday use, but is defined here to support

the concepts 'hour minute coordinate' and 'hour minute second coordinate'

second coordinate

Definition: relative atomic time coordinate that indicates a second of minute

Necessity: Each second coordinate indicates a second of minute that has the index equal to the

index of the second coordinate.

Necessity: Each <u>second coordinate</u> is greater than or equal to <u>0</u>. Necessity: Each <u>second coordinate</u> is less than or equal to <u>59</u>.

Example: second 45

Note: This type of time coordinate is not common in everyday use, but is defined here to support

the concept 'hour minute second coordinate'

hour minute coordinate

Definition: relative compound time coordinate that combines an hour coordinate and that

combines a minute coordinate, and that indicates a minute of day

Necessity: Each hour minute coordinate indicates a minute of day that has index 60 times the

index of the hour coordinate plus the index of the minute coordinate.

Description: An hour minute coordinate combines an hour coordinate and a minute coordinate to

indicate a minute of day.

Example: "11:23 a.m." combines the set_of {11 a.m, minute 23}, and indicates the minute of day that

has index 683

hour minute second coordinate

Definition: relative compound time coordinate that combines an hour coordinate and that

combines a minute coordinate and that combines a second coordinate and that

indicates a second of day

Necessity: Each hour minute second coordinate indicates a second of day that has index 3 600

times the index of the hour coordinate plus 60 times the index of the minute

coordinate plus the index of the second coordinate.

Example: "11:23:49 a.m." combines the set of {11 a.m, minute 23, second 49}, and indicates the

second of day that has index 36432

standard time coordinate

Definition: <u>time of day coordinate</u> that is an <u>hour coordinate</u> or <u>hour minute coordinate</u> or <u>hour</u>

minute second coordinate

Dictionary Basis: ISO 8601 (2.1.9, 'calendar date')

Note: standard time coordinates may be combined with time offsets, see clause 10.3.

Example: 3 p.m. Example: 15:00 Example: 15:00:35

13.5 Time of Day Comparisons and Conversions

Hours of day, minutes of day, and seconds of day may be compared with each other.

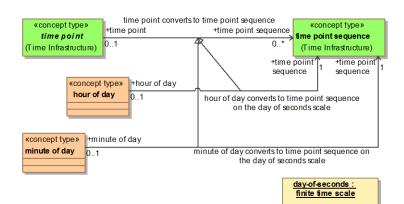

Figure 13.3 - Time of Day Conversions

The following Necessities identify which time of day time points can be compared by conversion to a common 'shared' time scale:

Each hour of day shares the day of minutes scale with each minute of day. Necessity:

Example: "10 a.m." can be compared with "10:39" on the day of minutes scale

Necessity: Each hour of day shares the day of seconds scale with each second of day.

"10 a.m." can be compared with "10:39:42" on the day of seconds scale Example:

Each minute of day shares the day of seconds scale with each second of day.

"10:39" can be compared with "10:54:48" on the day of seconds scale Necessity:

Example:

Hours of day and minutes of day can be converted to the day of seconds scale.

hour of day converts to time point sequence on the day of seconds scale

General Concept: time point converts to time point sequence on time scale

the $\underline{\text{time point sequence}}$ is on the $\underline{\text{day of seconds scale}}$ and the $\underline{\text{index}}$ of the $\underline{\text{first}}$ Definition:

time point of the time point sequence equals 3 600 times the index of the hour of day, and the index of the last time point of time point sequence is the index of the first

time point plus 3599

Description: The hour of day converts to a sequence of seconds of day whose indices are computed by

the formula.

Example: The hour of day that is indicated by "hour 0" converts to second of day 0 through second

ofday 3 599 on the day of seconds scale

minute of day converts to time point sequence on the day of seconds scale

time point converts to time point sequence on time scale General Concept:

the <u>time point sequence</u> is on the <u>day of seconds scale</u> and the <u>index</u> of the <u>first</u> Definition:

time point of time point sequence equals 60 times the index of minute of day, and the index of the last time point of time point sequence is the index of the first time

point plus 59

Description: The minute of day converts to a sequence of seconds of day whose indices are

computed by the formula.

Example: The minute of day that is indicated by "1:48" converts to second of day 6 480 through

second of day 6 539 on the day of seconds scale

13.6 Time Zones

In order to make local noon (12:00) coincide approximately with the Sun's zenith at the locale, authorities in each locale specify one or more local calendars to be used, during different seasons of a year, for commerce in the locale. A locale in which a standard calendar is used is called a "time zone." The governing authority over time zones is the national or state government of the locale. Many local calendars are named. For example, Pacific Daylight Time, Eastern Standard Time, British Summer Time. Two or more time zones may have the same name, e.g., there is an Eastern Standard Time in the U.S_ and another in Australia, and they are different time zones

A local calendar is UTC with a characteristic time offset from UTC by up to ±12 hours. These offsets are usually an integer number of hours or half hours. The nominal offset is zero at the Prime Meridian, +1 hour for each 15° of longitude east of the Prime Meridian, and -1 hour for each 15° of longitude west of the Prime Meridian. '+' means a particular reading of a clock set to the time of the local calendar occurs before a clock that is set to UTC has the same reading; '-' means the local reading occurs after the UTC reading. The duration between corresponding readings is the time offset. The 180° meridian is nominally the International Date Line: a date in locales west of the International Date Line (e.g., longitude 179°E) is one day ahead of the date in locales east of the International Date Line (e.g., longitude 179°W).

The time offset from UTC affects more than time of day for a local calendar. At any UTC time there is some locale that has a different local date that is one day before or after the UTC date: the date can be different as well as the hour and minute. For example, during periods when standard time is used in Australia (early April to early October), 18:00 UTC (19:00 BST in London) is 04:00 local time the next day in Sydney (UTC+10 hours); 04:00 UTC is 18:00 local time the previous day in Honolulu (UTC-10 hours); Honolulu and Sydney, being 20 hours apart, are on different dates for all but four hours each day (10:00 - 14:00 UTC that day). The approach adopted in this specification is to consider that each time zone has one or two distinguished local calendars.

A complete literal specification of a time interval includes a calendar specification as part of the time coordinate; otherwise there is a 24 hour ambiguity. For example, compare "July 4, 2010 12:00 PDT" to "July 4, 2010 12:00" or "July 4, 2010 to "July 4, 2010." Note the 24-hour ambiguity when the calendar specification is left out, not knowing where in the world the time is meant.

The intended calendar is often implied by the locale of the utterance of a time coordinate, or by the locale of the associated event, or by other context, but a calendar specification should be provided explicitly when necessary to remove all doubt. This is especially important in discourses that involve multiple time zones. When time coordinates are used in a discourse without specifying the time zone, it is assumed for purposes of comparison and date-time arithmetic that they are on the same calendar. Time references without calendar specifications in different discourses also without locale references are not prima facie comparable to within less than 24 hours.

A representation of a time offset may be combined with a date coordinate, a time of day coordinate, or a date time coordinate to indicate that the time coordinate is specified according to a local calendar that has that offset. The effect of the time offset is to shift the interpretation of the time coordinate with respect to UTC.

13.6.1 Calendar Offsets

This subclause defines the basic relationship between calendars that use the same nominal time scales and time points but use the time points to refer to different time intervals.

Commented [EB101]: Issue DTV 13-101 MOVE and REVISE text (from 10.5)

Moved (insertion) [3]

Deleted: Because of the rotation of the Earth, a separate calendar is needed for each time zone.

Deleted: given

Deleted: (UTC-5 hours)

Deleted: (UTC+10 hours)

Deleted: It will not do merely to use UTC with a time offset of the UTC day -of-hours scale for a local calendar: at any UTC time there is some locale that has a different local date that is one day before or after the UTC date: the date can be different as well as the hour and minute. For example, during periods when day light savings time is off in Australia (early April to early October), 18:00 UTC (19:00 BST in London) is 04:00 local time the next day in Sydney (UTC+10 hours); 04:00 UTC is 18:00 local time the previous day in Honolulu (UTC-10 hours); Honolulu and Sydney, being 20 hours apart, are on different dates for all but four hours each day (10:00 -14:00 UTC that day). The approach adopted in this specification is to consider that each time zone has one or two distinguished local cal endars.¶

Deleted: calendar

Deleted: for a particular time zone or for day light savings time

Commented [EB102]: Issue DTV 13-105 REPLACE text (whole subclause)

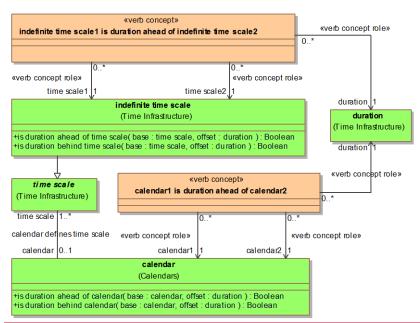

Figure 13.4 - Calendars and Time Offsets

indefinite time scale, is duration ahead of indefinite time scale,

Synonymous Form:	<u>indefinite time $scale_2$ is duration behind indefinite time $scale_1$</u>
Synonymous Form:	indefinite time scale ₁ = indefinite time scale ₂ + duration
Synonymous Form:	indefinite time $scale_2 = indefinite$ time $scale_1 - duration$
Definition:	the granularity of indefinite time scale 1 is the granularity of indefinite time scale 2 and
	each time point, of indefinite time scale, corresponds to a time interval, that starts
	duration before the time interval that is the instance of the time point, that is a time
	point of indefinite time scale 2 and that has an index that is equal to the index of time
	point₁
Note:	That is, the time scales have the same nominal time points but the correspondence to time
	intervals is adjusted by the time offset.
Note:	In particular, the time point on indefinite time scale ₂ that has the same index as the time
	point that defines the reference time interval for the indefinite time scale ₁ corresponds to a
	time interval that starts duration before the reference time interval.

calendar, is duration ahead of calendar,

Synonymous Form:	calendar ₂ is time offset behind calendar ₁
Synonymous Form:	calendar ₁ = calendar ₂ + duration
Synonymous Form:	calendar ₂ = calendar ₁ - duration
Definition:	each indefinite time scale, that is defined by calendar, is duration ahead of the
	indefinite time scale ₂ that is defined by calendar ₂ and that has the granularity of
	<u>indefinite time scale₁</u>
Description:	The two calendars have the same time scales, and the time scales correspond to time
	intervals that are duration apart.

Moved (insertion) [2]

Note:	All of the time scales defined by calendar, are considered to be the same duration ahead of
	the corresponding time scales of calendar ₂ , because the finite time scales are defined
	relative to time points on the indefinite time scales.
Example:	Eastern Standard Time (EST) is UTC - 5 hours, and Pacific Standard Time (PST) is UTC - 8 hours.
	Therefore, EST is 3 hours ahead of PST, and PST is 3 hours behind EST.
Example:	India Standard Time (IST) = UTC + 5 hours 30 minutes. Therefore IST is 13 hours 30 minutes
•	ahead of PST. And each Gregorian day in India begins 13 hours 30 minutes before the
	same Gregorian day in California.

ISO 8601 (2.1.13) concept type time point within a calendar day in accordance with UTC ISO 8601 (2.1.14) IEC 60050-111 time scale derived from Coordinated Universal Time, UTC, by a time offset established in a given location by the competent authority A place or region whose time of day is specified by a competent authority local time of day	
	All time zone calendars are correlated to UTC. UTC is officially maintained by the BIPM in cooperation with national metrology institutes or observatories around the world. See http://www.bipm.org/en/scientific/tai/time server.html. The UTC day of seconds scale differs from TALby the insertion of leap seconds (about every 18 months) to ensure approximate agreement with the time derived from the rotation of the Earth to within one second. The leap second adjustments make UTC a discontinuous time scale, because the Gregorian days in which the leap seconds occur have 86401 seconds. Thus, the UTC dayof seconds scale is the current number of leap seconds behind TAL. Businesses that are sensitive to elapsed seconds of day may prefer to use TAL instead. Temps Atomique International International Atomic Time indefinite time scale that is defined in a geocentric reference frame with the SI second as realized on the rotating geoid as the scale unit SL SL cites the "declaration of the CCDS. BIPM Com. Cons. DŽf. Seconde, 1980, 9, SL 5 and Metrologia, 1981, 17, 70". The granularity of the TAL Scale is second. The index origin of TAL is midnight Gregorian day 2443145 (1 January 1977 00:00:00). Julian Date 2443144.5 TAL is a continuous time scale of seconds, maintained by the Bureau international des poids et mesures (BIPM) as the average of over 200 hundred atomic clocks located in over 50 national laboratories. Time coordinates for TAL are given as Julian date and time of day, where each Julian day is

UTC is defined to be a calendar, because it defines the relationship of the Gregorian day

Deleted: <#>calendar that combines the Gregorian Calendar, a day-of-hours scale, an hour-of-minutes scale, and a minute-of-seconds scale Deleted: <#>UTC has granularity of second. Other calendars may be defined as multiples or fractions of For the purposes of this vocabulary, Deleted: <#>presumed to be Deleted: is adjusted

Deleted: Deleted: Formatted: Default Paragraph Font Deleted: time offset¶ role¶
duration that characterizes a comparison of two calendars¶
Duration between a given indication (e.g., 12:00:00.000) on a clock set to $\underline{\text{local time}}$ and the same indication on a clock set to $\underline{\text{UTC}}$ $\underline{\text{time}}$, where both of the clocks change at the same rate. Conventionally , a time offset is prefixed + to indicate that the local clock indication occurs before (is ahead of) the UTC indication, and – to indicate the local clock indication occurs after (is behind) the UTC indication: <u>local time</u> – <u>UTC time</u>. The sign is styled as a key word prefix to the duration to convey this precedence information. The number of a duration is always non-negative. Indian Standard Time – UTC = $+5\frac{1}{2}$ hours.¶

local calendar			
Definition:	calendar that is exactly one duration ahead of UTC or that is exactly one duration	·	Deleted: differs from
Reference Scheme:	<u>behind UTC</u> the time offset of the local calendar		Deleted: by a time offset
Example:	Pacific Daylight Time (UTC–7 hours), Eastern Standard Time (UTC–5 hours), British		Deleted: from UTC
Ехапріє.	Summer Time (UTC+1 hour), Indian Standard Time (UTC+5½ hours)		
Note:	Many, but not all, local calendars are named. Calendar names are not unique, e.g., EST in		
	the US and Australia. Many named local calendars may have the same time offset. For		
	example, both Central European Standard Time and Algeria Standard Time are UTC+1		
	hour. A local calendar does not need to be named; it is identified by its time offset from		
	UTC.		
Note:	ISO 8601 abbreviates time offsets by using only a signed four-digit number representing hours and minutes, omitting the "UTC" and "hours". Thus, IST is "+0530".		
Note:	Time references that are intended to be independent of changes to local calendars should		
1000.	be specified as UTC and a time offset.		
Example:	Most locations in the United States change between daylight time and summer time twice a		
	year, and the specifications for when the changes happen have themselves changed on		
	occasion. To specify noon in standard time in NY independent of local calendar, use		
	<u>'12:00-5:00'.</u>		

local calendar specifies time offset

Synonymous Form: time offset of local calendar

Definition: the time offset is the difference between the local calendar and UTC

Necessity: Each local calendar specifies exactly one time offset.

locale uses local calendar

Each locale uses exactly one local calendar at any given time.

time zone

Definition:	locale in which one or two local calendars is used		
Note:	When there are two calendars for a time zone, one is standard time and the other is daylig		
	savings time. The dates and time of day for changing between them is determined by local		
	authorities for each time zone.		
Note:	The Time Zone Database [Zoneinfo] documents the history of local time for many		
	locations. It is updated periodically to reflect changes made by political bodies to time zone		
	boundaries, UTC offsets, and daylight-saving rules.

Deleted: 20150301

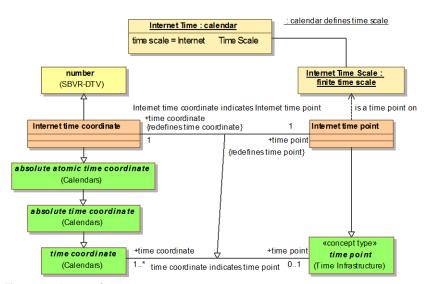

Figure 14.1 - Internet Calendar

14.2 Internet Calendar

Internet Time

Definition: calendar that keeps UTC time and that uses the Internet Time Scale

[NTP] Source:

Internet Time is based on UTC but is not necessarily always coincident with it (see [NTP] Note:

Appendix E.8 for a fuller explanation of reckoning the <u>Internet Time Scale</u> with <u>UTC</u>). <u>Internet</u> Time accounts for UTC's leap seconds, with a small uncertainty around the time of insertion

of a leap second. Accuracy of $\underline{\text{Internet Time}}$ relative to $\underline{\text{UTC}}$ is on the order of $\underline{\text{Imillisecond}}$. Stated precision is Necessity:

200 picose conds.

Internet Time Scale

 $\frac{\text{finite time scale whose granularity } is \ \underline{2^{32} \, \text{seconds}} \text{ and } \textit{whose } \underline{\text{cardinality }} is \ \underline{2^{64}} \text{ and } \textit{whose } \underline{\text{first }} \underline{2^{32} \, \text{time points }} \textit{correspond to } \underline{\text{January 1, }} \underline{\text{1,900 00:00:00 UTC}}$ Definition:

The data format of NTP is defined in [NTP] section 3.1 and Appendix A. The Internet Time Note:

Scale will overflow the 64 bits after about 136 years, in 2036. The IETF is considering a

revision of NTP (RFC 5905) that may likely extend its lifetime considerably.

Internet time coordinate

Definition: time coordinate that is a 64-bit unsigned fixed-point number having a 32 bit integer part

and 32 bit fractional part and that indicates the Internet time point that is the number

of seconds since January 1, 1900 00:00:00 UTC.

Internet time point

Concept Type: concept type Definition: time point that is on the Internet time scale and that is the number of seconds since January 1,1900 00:00:00 UTC.

15 Indexical Time Concepts (normative)

15.1 General

"Indexical" is a linguistic concept that refers to terms that make implicit reference to the speaker or the context of the communication. It includes words like "now," "here," "we," etc. This clause defines indexical terms for time periods that are in common business use.

The use of indexical terms in business vocabularies and rules can be ambiguous, and the practice is generally deprecated, but these concepts are needed for some use cases.

Indexical Time Vocabulary

General Concept: <u>terminological dictionary</u>

Language: English

Included Vocabulary: <u>Time of Day Vocabulary</u>
Included Vocabulary: <u>ISO Week Calendar Vocabulary</u>

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#IndexicalTimeVocabulary

15.2 Indexical Characteristics

These unary fact types locate time intervals relative to the fundamental concept 'time interval is past'. An alternative design choice would be to specify a fundamental concept 'current time' as a kind of 'time interval', and then define 'time interval is past', 'time interval is future', etc., in terms of 'current time'. One of them must be defined; otherwise the definitions are circular. But every time interval has a duration, and defining 'current time' implies specifying its duration. The advantage of making 'time interval is past' fundamental is that we need not give a duration for current time.

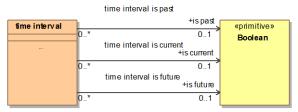

Figure 15.1 - Indexical Characteristics

Deleted: 20150301

time interval is past

Definition: <u>time interval</u> that is before some reference <u>time interval</u> that is defined by context

Note: <u>The reference</u> time interval is the time interval in which a rule is evaluated or applied. The

The reference <u>time interval</u> is the <u>time interval</u> in which a rule is evaluated or applied. That is, any <u>time interval</u> that *is past* is always *before* the <u>time interval</u> at which the rule is

used.

Example: The time interval identified by "January 1, 1900" is past with respect to a reference

time interval in 2012.

time interval is current

Synonymous Form: <u>time interval</u> is present <u>time interval</u> is now

Definition: time interval that includes a time interval that is past and a time interval that is not

past

Example: If the contract deadline is current...

time interval is future

Definition: time interval that includes no time interval that is in the past

Necessity: Each <u>time interval</u> that is future, is after each <u>time interval</u> that is past.

Example: The supplier may respond to the RFP only if the due date of the RFP is future.

These definitions of 'time interval is past', 'time interval is current', and 'time interval is future' are under-specified in the sense that many time intervals (of different durations) fit them. In particular, the verb concept 'time interval is future' includes the 'current time' reference time interval of the verb concept 'time interval is past'. Rules that compare time against 'current time' may be stated more precisely by referencing the indexicals given in sub clause 15.3, below. For example "if the contract due date is a future day ..." clearly tests the time interval given by the contract due date against a time interval that has a duration of 1day and an alignment against the Gregorian calendar, whereas "if the contract due date is future" may be interpreted with any "comparison granularity," such as 'second' or 'hour'.

15.3 Indexical Time Intervals

Indexical time concepts are noun concepts that are indexical references to time. To minimize confusion, the indexical time intervals defined in this clause follow a consistent designation pattern. These time intervals are distinguished by whether they define the immediate previous or subsequent time point of a given kind, any past or future time point of a given kind, or a time period of a specific duration that ends or begins at a reference time.

Table 15.1 summarizes the designation patterns for the indexical time intervals. The patterns may be combined with the designations of any <u>time units</u>. In the table, the symbol '...' stands for the designation of a <u>time unit</u>, such as '<u>day</u>', or 'second'.

Table 15.1 - Naming Pattern for Indexical Time Intervals

time intervals relative to 'current time'	Description	Examples
current	<u>Time intervals of a specific time point kind</u> that <u>are current</u> .	<u>current time</u>
last previous	<u>Time intervals</u> of a specific <u>time point kind</u> that <i>meet</i> the reference time.	last day
next subsequent	Time intervals of a specific time point kind that are met by the reference time.	next week

past prior earlier	Time intervals of a specific time point kind that are before the reference time.	past hour earlier month
future later	<u>Time intervals</u> of a specific <u>time point kind</u> that <i>are after</i> the reference time.	future month
preceding	Time periods of a specified duration that meet the reference time.	preceding year
following upcoming	<u>Time periods</u> of a specified <u>duration</u> that <i>are met by</i> the reference time.	following day

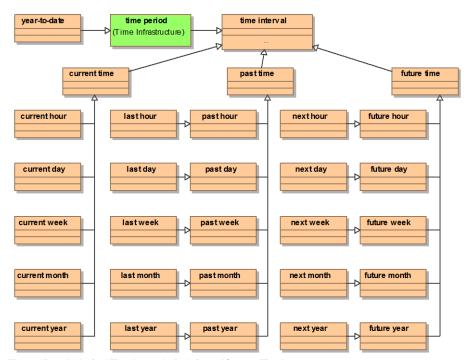

Figure 15.2 - Indexical Time Intervals Relative to 'Current Time'

Figure 15.3 - Indexical Time Periods Relative to 'Current Time'

current time

Synonym: <u>present time</u>

Definition: <u>time interval</u> that is current

Note: Every <u>time interval</u> that overlaps the "reference time interval" for '<u>time interval</u> is past is

a current time (one of many).

Example: If the reference time interval is the <u>current hour</u>, then the <u>calendar day</u>, <u>calendar week</u>,

calendar month, calendar year (etc.) that overlap the current hour are all current times.

past time

Synonym: <u>prior time</u> Synonym: <u>earlier time</u>

Definition: <u>time interval</u> that is past

Example: In any given calendar, if the reference time interval is denoted by "2012", then past time is

any time interval that is before 2012.

future time

Synonym: <u>latertime</u>

Definition: <u>time interval</u> that is future

Example: If the reference time interval is the <u>calendar day</u> of the title closing of a real estate

transaction, then $\underline{\text{future time}}$ is that $\underline{\text{calendar day}}$ and any later $\underline{\text{time interval}}$.

current hour

Concept Type: <u>unitary concept</u> General Concept: <u>current time</u> Definition: the time interval that instantiates an hour of day and that is current

Example: If the reference time interval is 10:32, then the <u>current hour</u> is a <u>time interval</u> denoted as

hour of day 10.

last hour

Synonym: <u>previoushour</u>
Concept Type: <u>unitary concept</u>
General Concept: <u>past hour</u>

Definition: the time interval that instantiates an hour of day and that meets the current hour

Example: If the reference time interval is 10:32, then the last hour is a time interval denoted as hour of

<u>day9</u>.

next hour

Synonym: subsequent hour
Concept Type: unitary concept
General Concept: future hour

Definition: the time interval that instantiates an hour of day and that is met by the current hour Example: If the reference time interval is 10:32, then the next hour is a time interval denoted as hour

<u>ofday11</u>.

past hour

Synonym: prior hour
Synonym: earlier hour
General Concept: past time

Definition: time interval that instantiates an hour of day and that is before the current hour

Definition: <u>time interval</u> that instantiates an hour of day that is past

Example: If the reference time interval is <u>10:32</u>, then one <u>past hour</u> is a <u>time interval</u> denoted as <u>hour</u>

ofday9. Another past hour is a time interval denoted as hour of day8.

future hour

Synonym: <u>later hour</u> General Concept: <u>future time</u>

Definition: time interval that instantiates an hour of day and that is after the current hour

Definition: <u>time interval that instantiates an hour of day that is future</u>

Example: If the reference time interval is 10:32, then one future hour is a time interval denoted as

<u>hour of day 11</u>. Another future hour is a <u>time interval</u> denoted as <u>hour of day 12</u>.

preceding hour

Concept Type: <u>unitary concept</u>
General Concept: <u>past time</u>

Definition: the hour period that meets a time interval that instantiates a minute of hour and that

is current

Example: If the reference time interval is 10:32, then the preceding hour is an hour period from 9:32

through <u>10:31</u>.

following hour

Synonym: upcoming hour
Concept Type: unitary concept
General Concept: future time

the <u>hour period</u> that is met by a <u>time interval</u> that instantiates a <u>minute of hour</u> and Definition:

that is current

If the reference time interal is 10:32, then the following hour is an hour period from 10:33 Example:

through 11:32.

current day

Concept Type: unitary concept General Concept: current time

Definition: the time interval that instantiates some calendar day and that is current

If the reference time interval is <u>July 7 10:32</u>, then the <u>current day</u> is a <u>time interval</u> denoted Example:

as July 7.

last day

Synonym: previousday Concept Type: unitary concept

General Concept: past day

Definition: the time interval that instantiates a calendar day and that meets the current day Example:

If the reference time interval is <u>July 7 10:32</u>, then the <u>last day</u> is a <u>time interval</u> denoted as

next day

subsequent day Synonym: Concept Type: unitary concept General Concept: future day

the time interval that instantiates a calendar day and that is met by the current day Definition:

Example: If the reference time interval is July 7, then the next day is July 8.

past day

Synonym: prior day Synonym: earlier day past time General Concept:

time interval that instantiates a calendar day and that is before the current day Definition:

time interval that instantiates a calendar day that is past Definition:

Example: If the reference time interval is <u>July 7</u>, then one <u>past day</u> is a <u>time interval</u> denoted by <u>July 6</u>

and another is a time interval denoted by July 5.

future day

Synonym: <u>later day</u> General Concept: future time

time interval that instantiates a calendar day and that is after the current day Definition:

Definition: time interval that instantiates a calendar day that is future

If the reference time interval is <u>July 7</u>, then one <u>future day</u> is a <u>time interval</u> that is denoted Example:

by <u>July 8</u>, and another <u>future day</u> is a <u>time interval</u> that is denoted by <u>July 9</u>.

preceding day

Concept Type: unitary concept General Concept: past time

Definition: the day period that meets a time interval that instantiates a minute of hour and that

is current

If the reference time interval is July 7 10:32, then the preceding day is a day period from Example:

July 6 10:32 through July 7 10:31.

following day

Synonym: upcoming day Concept Type: unitary concept General Concept: future time

Definition: the day period that is met by a time interval that instantiates a minute of hour and

that is current

If the reference time interval is July 7 10:32, then the following day is a day period from Example:

July 7 10:33 through July 8 10:32

current week

Concept Type: unitary concept General Concept: current time

Definition: the $\underline{\text{time interval}}$ that $instantiates \underline{\text{some }}$ calendar week and that is current

Example: If the reference time interval is week 15 day 3, then the current week is a time interval that

instantiates week 15.

last week

Synonym: previousweek Concept Type: unitary concept General Concept: past week

Definition: the time interval that instantiates a calendar week and that meets the current week Example:

If the reference time interval is week 15 day 3, then the last week is a time interval that

instantiates week14.

next week

Synonym: subsequent week Concept Type: unitary concept General Concept: future week

Definition: the time interval that instantiates a calendar week and that is met by the current

Example: If the reference time interval is week 15 day3, then the next week is a time interval that

instantiates week 16.

past week

Synonym: prior week Synonym: earlier week General Concept: past time

Definition: time interval that instantiates a calendar week and that precedes the current week

time interval that instantiates a calendar week that is past Definition:

Example: If the reference time interval is week 15 day 3, then one past week is a time interval that

instantiates week14, and another past week is a time interval that instantiates week13.

future week

Synonym: later week General Concept: future time

Definition: time interval that instantiates a calendar week and that is after the current week

Definition: time interval that instantiates a calendar week that is future

If the reference time interval is $\underline{\text{week}15\,\text{day3}}$, then one $\underline{\text{future week}}$ is a $\underline{\text{time interval}}$ that Example:

instantiates week16 and another future week is a time interval that instantiates week17.

preceding week

Concept Type: unitary concept General Concept: past time

the week period that meets a time interval that instantiates a minute of hour and Definition:

that is current

If the reference time interval is $\underline{\text{week15 day3}}$, then the $\underline{\text{preceding week}}$ is a $\underline{\text{week period}}$ that is from $\underline{\text{week14 day3}}$ through $\underline{\text{week15 day2}}$. Example:

following week

Concept Type: unitary concept General Concept: future time

Definition: the week period that is met by a time interval that instantiates a minute of hour and

that is current

If the reference time interval is week 15 day 3, then the following week is a week period Example:

that is from week15 day4 through week16 day3.

current month

Concept Type: unitary concept General Concept: current time

Definition: the time interval that instantiates some calendar month and that is current If the reference time interval is <u>July 7</u>, then the <u>current month</u> is a <u>time interval</u> that Example:

instantiates <u>July</u>.

last month

Synonym: previousmonth Concept Type: unitary concept General Concept: past month

the time interval that instantiates a calendar month and that meets the current Definition:

<u>month</u>

If the reference time interval is <u>July 7</u>, then the <u>last month</u> is a <u>time interval</u> that instantiates Example:

June.

next month

Synonym: subsequent month General Concept: future month Concept Type: unitary concept

Definition: the time interval that instantiates a calendar month and that is met by the current

month

If the reference time interval is <u>July 7</u>, then the <u>next month</u> is a <u>time interval</u> that Example:

instantiates August.

past month

Synonym: prior month Synonym: earlier month General Concept: past time

time interval that instantiates a calendar month and that precedes the current month Definition:

Definition: time interval that instantiates a calendar month that is past Example: If the reference time interval is <u>July 7</u>, then one <u>past month</u> is a <u>time interval</u> that

instantiates June, and another past month is a time interval that instantiates May.

future month

Synonym: <u>later month</u> General Concept: <u>future time</u>

Definition: time interval that instantiates a calendar month and that is after the current month

Definition: <u>time interval</u> that instantiates a <u>calendar month</u> that is future

Example: If the reference time interval is July 7, then one future month is a time interval that

instantiates <u>August</u>, and another <u>future month</u> is a <u>time interval</u> that instantiates <u>September</u>.

preceding month

Concept Type: <u>unitary concept</u>
General Concept: <u>past time</u>

Definition: the month period that meets a time interval that instantiates a Gregorian day of year

and that is current

Necessity: The <u>duration</u> of the <u>preceding month</u> is the <u>duration</u> of the <u>last month</u>.

Note: The previous Necessity addresses the varying <u>duration</u> of <u>calendar months</u>.

Example: If the reference time interval is <u>July 7</u>, then <u>preceding month</u> is a <u>month period</u> from <u>June</u>

7 through July 6.

Example: If the reference time interval is <u>June 7</u>, then <u>preceding month</u> is a <u>month period</u> from <u>May</u>

7 through June 6.

following month

Concept Type: <u>unitary concept</u>
General Concept: <u>future time</u>

Definition: the month period that is met by a time interval that instantiates a Gregorian day of

year and that is current

Necessity: The <u>duration of the following month is the duration of the current month.</u>

Note: The previous Necessity addresses the varying <u>duration of calendar months.</u>

Example: If the reference time interval is <u>July 7</u>, then <u>following month</u> is a <u>month period</u> from <u>July 8</u>

through August 7

Example: If the reference time interval is <u>June 7</u>, then <u>following month</u> is a <u>month period</u> from <u>June</u>

 $\underline{8}$ through $\underline{\text{July 7}}$.

current year

Concept Type: <u>unitary concept</u> General Concept: <u>current time</u>

Definition: the time interval that instantiates some calendar year and that is current

Example: If the reference time interval is <u>July 11, 2011</u>, then the <u>current year</u> is the <u>time interval</u> that

instantiates 2011.

last year

Synonym: <u>previousyear</u>
Concept Type: <u>unitary concept</u>
General Concept: <u>past year</u>

Definition: the time interval that instantiates a calendar year and that meets the current year

Example: If the reference time interval is <u>July 11, 2011</u>, then the <u>last year</u> is the <u>time interval</u> that

instantiates 2010

next year

Synonym: subsequent year Concept Type: unitary concept General Concept: future year

Definition: the time interval that instantiates a calendar year and that is met by the current year Example:

If the reference time interval is July 11 2011, then the next year is the time interval that

instantiates 2010.

past year

Synonym: prior year Synonym: earlier year General Concept: past time

time interval that instantiates a calendar year and that precedes the current year Definition:

time interval that instantiates a calendar year that is past Definition:

Example: If the reference time interval is <u>July 11 2011</u>, then one <u>past year</u> is the <u>time interval</u> that

instantiates 2010 and another past year is the time interval that instantiates 2009.

future year

Synonym: <u>later year</u> General Concept: future time

Definition: time interval that instantiates a calendar year and that is after the current year

Definition: time interval that instantiates a calendar year that is future

If the reference time interval is <u>July 7 2011</u>, then one <u>future year</u> is the <u>time interval</u> Example:

denoted by 2012 and another future year is the time interval denoted by 2013.

preceding year

Concept Type: unitary concept General Concept: past time

Definition: the year period that meets a time interval that instantiates a day of year and that is

current

The duration of the preceding year is the duration of the last year. Necessity: Note: The previous Necessity addresses the varying duration of calendar years.

If the reference time interval is <u>July 11 2011</u>, then the <u>preceding year</u> is the <u>year period</u> Example:

from July 11 2010 through July 10 2011.

following year

upcoming year Synonym: Concept Type: unitary concept General Concept: future time

Definition: the year period that is met by a time interval that instantiates a day of year and that

Necessity: The duration of the following year is the duration of the current year. The previous Necessity addresses the varying duration of calendar years. Note:

Example: If the reference time interval is <u>July 7 2011</u>, then the <u>following year</u> is the <u>year period</u> from

July 8 2011 through August 7 2012.

year to date

Definition: the time period that starts on calendar day 1 of the current year and that ends on the

current day

If the reference time interval is July 7, 2011, then year to date is July 1, 2011 through July 7, Example:

16 Situations (normative)

16.1 General

Situations Vocabulary

General Concept: terminological dictionary

Language: **English**

Included Vocabulary:

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#SituationsVocabulary

This clause provides a vocabulary for relating situations to time intervals and durations; that is, it provides the basic vocabulary for writing rules or facts about the relationship between situations, events or activities and time. This treatment is motivated by the discussion in [Parsons] and [Menzel].

This specification relies on the idea of 'possible world' that is introduced in SBVR and derived from [Plantinga] - a specific collection of things and relationships that could be described by a set of consistent assertions (an SBVR 'fact model'), regardless of how that world relates to what we perceive as reality. Further, this specification uses the term 'universe of discourse' (or 'world of interest') to refer to the particular possible world that is chosen as the basis for determining what is 'true' or 'actual' with respect to a use of the ontology for reasoning and decision making. The conventional first-order logic treatment of time is: a different time is a different (possible) world. This specification treats time as an aspect of every possible world, so that any possible world can have a present, a past, and a future.

Consider the following rule that could exist in EU-Rent:

It is prohibited that a renter has possession of more than one rental car.

Rules are evaluated with respect to possible worlds, each of which has a particular current time. The prohibition is of a renter possessing more than one rental car in any possible world, that is, at any particular current time. Rationale clause 7.15 further discusses the meaning of rules with respect to time.

SBVR defines the concepts 'state of affairs' and 'state of affairs is actual' as the basis for determining the truth of propositions in terms of the facts of a universe of discourse. Sub clause 16.2 defines 'situation kind' and 'occurrence' as specializations of 'state of affairs' in order to distinguish potential situations from actual happenings, which have different relationships to time. Sub clauses 16.3 through 16.7 specify these temporal relationships. Sub clause 16.8 integrates the Date-Time Vocabulary concepts with 'state of affairs' and 'proposition'. Sub clause 16.9 introduces concepts that support tense and aspect as used in human languages.

Deleted: 20150301

16.2 Situation Kinds and Models

Figure 16.1 describes two principal concepts – <u>situation kind</u>, and <u>occurrence</u> – and the definitive relationships among them. '<u>Situation kind</u>' and its specializations are types of events, activities and situations – the elements of process and activity models. They represent potential <u>states of affairs</u> that may be instantiated, perhaps many times, in the real business environment. These potential <u>states of affairs</u> may be planned for, budgeted for, dreamed of, feared, etc. '<u>Occurrences'</u> are real happenings in the business environment. Each <u>situation kind</u> may have multiple <u>occurrences</u>. For example, a business may plan for the situation "power failure that shuts down production", which may have multiple occurrences. These concepts are parallel to the BPMN ideas of an activity/event model element (<u>situation kind</u>) and an activity/event instance (<u>occurrence</u>).

'Situation kind' is further specialized as 'general situation kind' (a situation kind that may have multiple occurrences) and 'individual situation kind' (a situation kind that has most one occurrence). Typically, individual situation kinds refine general situation kinds by adding distinguishing characteristics. For example, the "power failure that shut down production on Friday" refers to an individual situation kind that refines the general situation kind "power failure that shuts down production". Ordinary English usage blurs the distinction between an individual situation kind and its occurrence. The Date-Time Vocabulary supports that typical usage by providing verb concepts that access the time of the single occurrence of an individual situation kind.

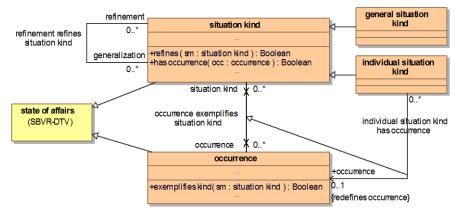

Figure 16.1 - Situation Kinds and Occurrences

situation kind

Synonym: <u>occurrence kind</u>

Definition: state of affairs that may or may not happen in some possible world

Note: A <u>situation kind</u> may be seen as a type of situation, event or activity that may occur,

perhaps more than once, or as a potential state of affairs that may be planned for, budgeted

for, feared, dreamed about, etc.

Example: Building codes often require special accommodations for building fires, understood as a

situation kind. Some buildings may have one or more fires, others may never have a fire,

but the requirements are not specific to individual fires.

Necessity: Each situation kind is either a general situation kind or an individual situation kind.

occurrence

Definition: <u>state of affairs that</u> is a happening in the universe of discourse

Note: An <u>occurrence</u> is an actual situation at some place and time in the <u>possible world</u> chosen

for the universe of discourse.

Note: This is a primitive concept.

Example: An occurrence of 'fire' can burn you.

Example: If a possible world includes all of December 2010, the physical flight of an aircraft from

Washington to Minneapolis on <u>December 20, 2010</u> from $\frac{7:00}{1:00}$ to $\frac{9:00}{1:00}$ EST is an <u>occurrence</u> in that world. In a <u>possible world</u> that is described by a <u>fact model</u> that includes flights, the flight of the aircraft exists. Any statement about all flights includes the particular flight. It <u>occurs within</u> December 2010 and <u>within</u> December 20, 2010, but it <u>occurs for</u> only the specified 2-hour <u>time interval</u>. It <u>occurs throughout</u> every <u>time interval</u> that is within

that 2-hour time interval.

occurrence exemplifies situation kind

Synonymous Form: situation kind has occurrence

Definition: the <u>occurrence</u> is a realization of the <u>situation kind</u>

Note: This is a primitive concept.

Possibility: Each <u>occurrence</u> exemplifies zero or more <u>situation kinds</u>.

Possibility: Each situation kind has zero or more occurrences.

CLIF Axiom: (forall (s occ)

(if ("situation kind has occurrence" s occ)

(and ("situation kind" s) (occurrence occ))))

Example: The <u>proposition</u> "EU-Rent rents car 123 to customer abc" corresponds to a <u>situation kind</u>

that may have an occurrence.

individual situation kind

Definition: <u>situation kind</u> that has at most one <u>occurrence</u> in each possible world

Necessity: Each individual situation kind has at most one occurrence.

Example: The <u>situation kind</u> that is described by the <u>proposition</u> "EU-Rent was incorporated on

January 1, 2003" is an <u>individual situation kind</u> because it has just one <u>occurrence</u>.

The distinction between an individual situation kind and its occurrence is often blurred in

ordinary English.

general situation kind

Definition: <u>situation kind</u> that is not an individual situation kind

Note: This concept is defined in contrast to 'individual situation kind' not because there is any

characteristic that distinguishes 'general situation kind' from 'situation kind'.

Note: A <u>situation kind</u> is a <u>general situation kind</u> if it can be exemplified by more than one <u>occurrence</u> in some <u>possible world</u>, even when it cannot have more than one <u>occurrence</u>

in the possible world chosen to be the universe of discourse.

Possibility: Each general situation kind has more than one occurrence.

Example: The <u>situation kind</u> that *is described by* "EU-Rent rents a car to a customer" is a <u>general</u>

situation kind if and only if there are multiple occurrences described by this situation

kind.

refinement

Note:

Definition: situation kind that has no occurrence that does not exemplify a given situation kind

Concept Type: role

refinement refines situation kind

Synonymous Form: situation kind has refinement

Definition: Each occurrence of the refinement exemplifies the situation kind

Example: The individual situation kind described by "flight 123 from Washington to Minneapolis

on December 20, 2010 arrives at 2pm" refines the general situation kind described by

"flight from Washington to Minneapolis arrives at 2pm."

Note: The refines fact type defines a partial ordering relationship among situation kinds that is

analogous to the specialization/subtype relationship among concepts.

generalization

Definition: <u>situation kind</u> that is exemplified by each <u>occurrence</u> of a given <u>situation kind</u>

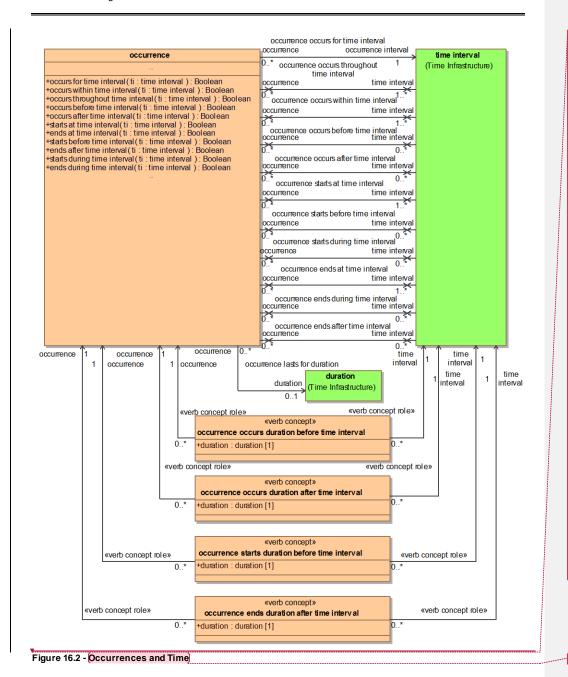

Concept Type: role

situation kind has generalization

Definition: Each occurrence of the <u>situation kind</u> exemplifies the <u>generalization</u>
Note: This is the inverse relationship to <u>situation kind</u> has <u>refinement</u>.

16.3 Occurrences and Time

An $\underline{\text{occurrence}}$ is an actual happening in the world of interest. This sub clause provides a vocabulary for relating $\underline{\text{occurrences}}$ to $\underline{\text{time intervals}}$ and $\underline{\text{durations}}$.

occurrence occurs for time interval (ti: time interval): Boolean +occurs for time interval (ti: time interval): Boolean +occurs within time interval (ti: time interval): Boolean +occurs within time interval (ti: time interval): Boolean +dats at time interval (ti: time interval): Boolean +dats before time interval (ti: time interval): Boolean +dats before time interval (ti: time interval): Boolean +dats during time interval (ti: time interval): Boolean +dats during time interval (ti: time interval): Boolean +dats during time interval (ti: time interval): Boolean +dats for duration (di: duration): Boolean +dats for duration (di: duration): time interval +the duration preceding(d:duration): time interval +the duration following(d:duration): time interval occurrenc occurrence occurrence occurrence occurrence «verb concept occurren +duration «verb concept role occurre 0 * +duration «verb concept role» +duration 0..* «verb concept role» occum 0..* +duration Deleted:

occurrence occurs throughout time interval

Synonymous Form: occurrence throughout time interval

Definition: the occurrence happens continuously, without interruption, in each time interval2 that is

part of the time interval

Note: This is a "primitive concept" - the fundamental relationship between occurrences and

time. It cannot be defined in terms of other concepts. The idea is that an occurrence

occurs at all times in some sufficiently small time interval.

Possibility: The occurrence may occur throughout some time interval₂ that is not part of the

time interval.

Note: That is, the occurrence could occur throughout a longer time interval that includes other

CLIF Axiom: time intervals. (forall (occ ti)

(if ("occurrence occurs throughout time interval" occ ti)

                                      time interval'(t3))
                          The <u>occurrence interval</u> is the maximal <u>time interval</u> in which the individual <u>occurrence</u>
Note:
                          occurs. The occurrence interval is immediately preceded and followed by time intervals
                          when the occurrence does not happen.
                          Each occurrence occurs for exactly one occurrence interval.
Necessity:
CLIF Axiom:
                          (forall (occ) (exists (t)
                            (and
                             ("occurrence occurs for occurrence interval" occ t)
                             (forall (t2)
                              (if (occurrence occurs for occurrence interval" occ t2)
                                  (= t2 t)))
Possibility:
                          Zero or more occurrences that exemplify a given general situation kind occur for a
                           given occurrence interval.
Example:
                          The <u>occurrence</u> that is a specific flight of a specific aircraft <u>occurs for the occurrence</u>
                          interval from the airplane's takeoff to the airplane's landing.
                          No occurrence "recurs." An occurrence is an individual event; a "recurrence" is a different
Note:
                          event, being distinguished by occurring for different time interval. What "recurs" is the
                          common situation kind.
Note:
                          A former occurrence is an occurrence that occurs over some occurrence interval that
                          is in the past. A planned occurrence is usually an occurrence that occurs over some
                          future occurrence interval. A goal is a situation kind that may have an occurrence at
                          some future time.
Note:
                          The occurrence interval is an essential intrinsic property of an occurrence, but it may not
                          be known or specified, and it may not be relevant to every business model. For some uses,
```

The building will be completed within 2015. Example:

16.4 Temporal Ordering of Occurrences

Business processes and many rules constrain the time order of activities and events without specifying the actual times. And in general, these rules refer to activities and events as situation kinds. But only individual occurrences can occur in temporal order. So, in fact, only occurrences are ordered. The following verb concepts facilitate careful specification of such usages.

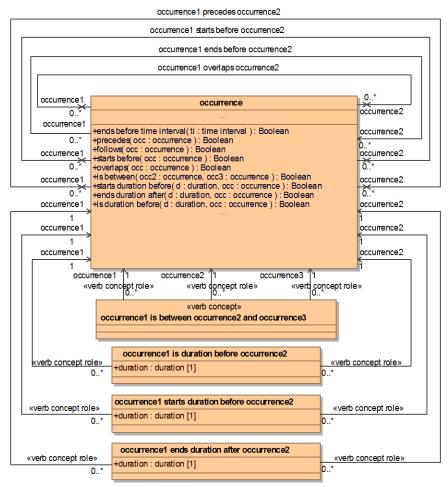

Figure 16.3 - Temporal Ordering of Occurrences

occurrence₁ precedes occurrence₂

occurrence₁ is duration after occurrence₂

Synonymous Form: occurrence₁ starts duration after occurrence₂ occurrence₂ is duration before occurrence₁
Synonymous Form: occurrence₂ ends duration before occurrence₁

Definition: the occurrence interval of occurrence is duration after the occurrence interval of

occurrence₂

Description: The time between the two <u>occurrences</u> is the given <u>duration</u>.

occurrence₁ starts duration before occurrence₂

Definition: the occurrence interval of occurrence₁ starts duration before the occurrence interval

of occurrence₂

Description: One <u>occurrence</u> starts <u>duration</u> before the other <u>occurrence</u> starts.

Note: This says nothing about the relationship between occurrence2 and the end of occurrence1

occurrence₁ ends duration after occurrence₂

Definition: the <u>occurrence interval</u> of <u>occurrence_1</u> ends <u>duration</u> after the <u>occurrence interval</u> of

occurrence₂

Description: One <u>occurrence</u> ends <u>duration</u> after the other <u>occurrence</u> ends.

Note: This says nothing about the relationship between occurrence2 and the start of occurrence1

16.5 Situation Kinds and Time

This sub clause provides the basic vocabulary for writing rules or facts about the relationship between situation Kinds and time.

Business processes and many rules constrain the timing of activities and events. In general, these rules refer to activities and events using situation kinds. A process specification assumes that what is being described is the sequencing of occurrences in an individual instance of the process. That is, the individual occurrences are described by the nature of the happening (the situation kind) and whatever information identifies the process instance. The fundamental notion here is that a situation kind 'occurs' at any time it is exemplified by an actual occurrence in the world of interest, as discussed in 16.3.

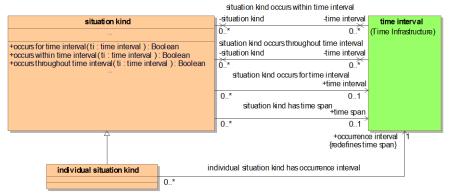

Figure 16.4 - Situation Kinds and Time

situation kind occurs throughout time interval

Synonymous Form: <u>situation kind</u> throughout time interval

Definition: some occurrence of the situation kind occurs throughout the time interval

Possibility: A situation kind may occur throughout no time interval.

situation kind occurs within time interval

Synonymous Form: <u>situation kind within time interval</u>
Synonymous Form: <u>situation kind in time interval</u>
Synonymous Form: <u>situation kind attime interval</u>
Synonymous Form: <u>situation kind attime interval</u>
Synonymous Form: <u>situation kind attime interval</u>

Definition: some occurrence of the situation kind occurs within the time interval

Example: The situation kind "soldiers are engaged in battle" occurred within the time interval that

has the time coordinate "14 October 1066".

Example: "Flight 70 landed in Minneapolis at 9:12 on May 13, 2011."

situation kind occurs for time interval

Definition: some occurrence of the situation kind occurs for the time interval
Necessity: Each individual situation kind occurs for at most one time interval.
Possibility: A general situation kind occurs for more than one time interval.

Note: For an <u>individual situation kind</u>, the <u>time interval</u> is unique. For a <u>general situation</u>

kind, the model and the time interval may uniquely identify an occurrence.

time span

Example:

General Concept: <u>time interval</u>
Concept Type: <u>role</u>

situation kind has time span

Definition: the occurrence interval of each occurrence of situation kind is part of time span and

no time interval that is part of time span is before the occurrence interval of each occurrence of situation kind and no time interval that is part of time span is after the

occurrence interval of each occurrence of situation kind

Description: The <u>time span</u> is the smallest <u>time interval</u> that contains the <u>occurrence intervals</u> of all

the occurrences in a given situation kind.

Note: A general situation kind may specify a constraint on the time interval of all of its

occurrences, by stating the time span for the general situation kind, or stating a constraint on it. Individual situation kinds that refine the general situation kind each resolve the time down to a particular occurrence interval that must be within the time

<u>span</u>.

Example: "The meetings will be weekly for the next three months" describes a <u>general situation</u>

kind whose time span is the specified time interval of the next three months. There can be a schedule of these meetings, giving the particular time for each meeting, which is an

individual situation kind.

Example: The <u>time span</u> of all the discount offers (a <u>general situation kind</u>) is within July 2011. A

particular discount (an individual situation kind) offer occurs for July 13 from 2-3pm.

The proposition "the meetings are scheduled for each Monday of July 2011" describes a

general situation kind whose time span is within the time interval "July 2011." If the

individual meetings are held, then they occur within the Mondays of July 2011.

individual situation kind has occurrence interval

Definition: the occurrence interval is the time span of the individual situation kind

Necessity: Each individual situation kind has at most one occurrence interval.

Note: The time span of an individual situation kind is exactly the occurrence interval of its

only occurrence.

Example: The occurrence interval of the Great Fire of London was 2 September 1666 through

5 September 1666 (English old style calendar).

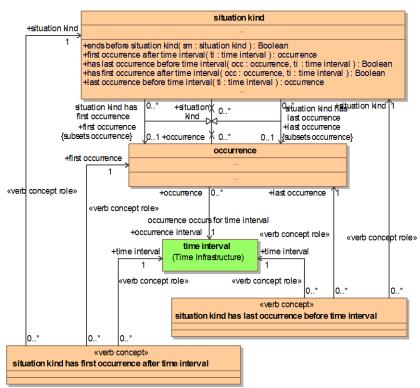

Figure 16.5 - First and last occurrences of situation kinds

first occurrence

General Concept: occurrence
Concept Type: role

situation kind has first occurrence after time interval

Synonymous Form: first occurrence of situation kind after time interval

Definition: the first occurrence exemplifies the situation kind and the first occurrence occurs

after the time interval and no occurrence that exemplifies the situation kind and that

occurs after the time interval starts before the first occurrence

	<u>December 2012</u> occurred over the <u>time interval</u> <u>21 April 1972</u> <u>through <u>24 April 1972</u>.</u>

16.6 Temporal Ordering of Situation Kinds

Business processes and many rules constrain the time order of activities and events without specifying the actual times. And in general, these rules refer to activities and events as <u>situation kinds</u>. Only individual <u>occurrences</u> actually have temporal ordering, but assigning such an ordering to the <u>situation kinds</u> themselves constrains the ordering of the actual <u>occurrences</u>. The following verb concepts facilitate careful specification of such usages.

                                     (if
                                      (and
                                        ("situation kind has occurrence" s1 o1)
                                        ("situation kind has occurrence" s2 o2))
                                      ("occurrence1 starts before occurrence2" o1 o2)))
                               context _'situation kind'
    OCL Definition:
                               def: _'situation kind1 starts before situation kind2'
                                  (s2: _'situation kind'): Boolean
                                  self.occurrence. 'starts before'(s2.occurrence)
                               This verb concept permits comparing the starting times of two situation kinds. This is
    Note:
                               primarily used for individual situation kinds.
    Example:
                               The procession must not start before the band plays.
situation kind ends before situation kind
    Synonymous Form:
                               situation kind2 ends after situation kind1
    Definition:
                               each occurrence of situation kind1 ends before each occurrence of situation kind2
    CLIF Definition:
                               (forall (s1 s2)
                                (iff ("situation kind1 ends before situation kind2" s1 s2)
                                  (and
                                    ("situation kind" s1) ("situation kind" s2)
                                    (forall (o1 o2)
                                     (if
                                      (and
                                        ("situation kind has occurrence" s1 o1)
                                        ("situation kind has occurrence" s2 o2))
                                      ("occurrence1 ends before occurrence2" o1 o2)))
    OCL Definition:
                               context _'situation kind'
                               def: _'situation kind1 ends before situation kind2'
                                  (s2: _'situation kind'): Boolean
                                  self.occurrence._'ends before'(s2.occurrence)
    Note:
                               This verb concept permits comparing the ending times of two situation kinds without
                               regard to their start times. This is primarily used for individual situation kinds.
    Example:
                               The delivery must be completed before the contract expires.
situation kind<sub>1</sub> overlaps situation kind<sub>2</sub>
```

Synonymous Form: situation kind₁ while situation kind₂ Synonymous Form: situation kind₁ occurs while situation kind₂

Definition: each occurrence of situation kind overlaps some occurrence occur

```
CLIF Definition:
                           (forall (s1 s2)
                           (iff ("situation kind1 overlaps situation kind2" s1 s2)
                            (and
                             ("situation kind" s1) ("situation kind" s2)
                             (forall (o1 o2)
                              (and
                                (occurrence o1) (occurrence o2)
                                (if (and
                                      ("situation kind has occurrence" s1 o1)
                                      ("situation kind has occurrence" s2 o2))
                                   ("occurrence1 overlaps occurrence2" o1 o2)))))))
OCL Definition:
                           context _'situation kind'
                           def: _'situation kind1 overlaps situation kind2'
                              (s2: _'situation kind') : Boolean
                              self._'occurrence'.overlaps (s2._'occurrence')

situation kind, is between situation kind, and situation kind,

Synonymous Form: <u>situation kind_1 between situation kind_2 and situation kind_3</u>
Synonymous Form: <u>situation kind_1 is between situation kind_2 to situation kind_3</u>
Synonymous Form: <u>situation kind_1 between situation kind_2 to situation kind_3</u>

Definition: <u>situation kind_1 follows situation kind_2 and situation kind_1 precedes situation kind_3</u>

Note: This verb concept permits comparing the time order of three <u>situation kinds</u>. This is most

Note: useful in ordering individual situation kinds, but it has broader use.

Example: When heading south, one crosses the equator between leaving Hawaii and arriving in

Sydney.

16.7 Specification of Time Intervals Using Situations

This sub clause defines concepts related to the use of <u>occurrences</u> and <u>individual situation kinds</u> to specify <u>time intervals</u>.

16.7.1 Specifying time intervals using occurrences

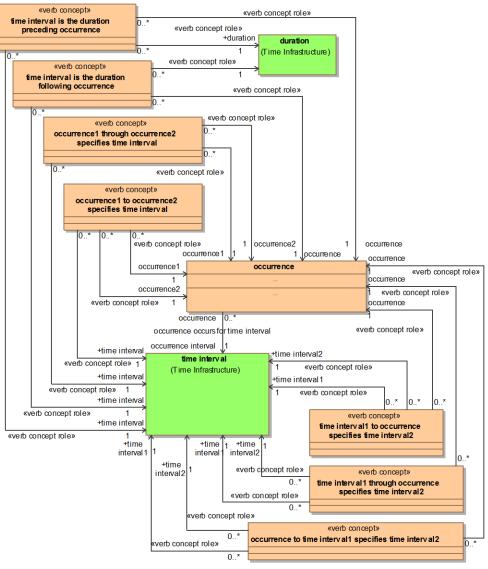

Figure 16.7 - Time intervals specified by occurrences

time interval, through occurrence specifies time interval,

 $Synonymous Form: \underline{time\ interval_1\ through\ occurrence}$

Commented [EB116]: reformatted, more in subclause
Formatted: Default Paragraph Font

dtc/2016-02-21

Synonymous Form: <u>time interval_2 is time interval_1 through occurrence</u>
Synonymous Form: <u>occurrence through time interval_1 specifies time interval_2</u>

Synonymous Form: occurrence through time interval

Synonymous Form: <u>time interval</u> is <u>occurrence</u> through <u>time interval</u>

Definition: the time interval₂ is the time interval₁ plus the occurrence interval of the occurrence

Description: The <u>time interval</u> extends from the start of <u>time interval</u> through the end of the

occurrence.

Note: The definition is correct for both the 'time interval through occurrence' and 'occurrence

through time interval, forms.

Example: The contract signing through 2012.

occurrence through occurrence specifies time interval

Synonymous Form: occurrence₁ through occurrence₂

Synonymous Form: time interval is occurrence through occurrence

Definition: the time interval is the occurrence interval of the occurrence plus the occurrence

interval of the occurrence2

Description: The <u>time interval</u> extends from the start of <u>occurrence</u> through the end of <u>occurrence</u>.

Example: The contract signing through the termination of the contract.

time interval, to occurrence specifies time interval,

Synonymous Form: <u>time interval</u> to <u>occurrence</u>

Synonymous Form: <u>time interval_1</u> is <u>time interval_1</u> to <u>occurrence</u>
Synonymous Form: <u>time interval_1</u> until <u>occurrence specifies time interval_2</u>

Synonymous Form: <u>time interval</u> until <u>occurrence</u>

Synonymous Form: <u>time interval</u> is <u>time interval</u> until <u>occurrence</u>

Definition: the time interval₂ is the time interval₁ to the occurrence interval of the occurrence

Description: Time interval₂ extends from the start of time interval₁ up to, but not including, the start of

the occurrence.

Example: Primordiality to the inauguration of the President.

occurrence to time interval, specifies time interval

Synonymous Form: occurrence to time interval₁

Synonymous Form: <u>occurrence to time interval_1 is time interval_2</u>

Synonymous Form: <u>occurrence_until_time_interval_specifies_time_interval_2</u>

Synonymous Form: <u>occurrence until time interval</u>1

Synonymous Form: occurrence until time interval₁ is time interval₂

Definition: the time interval₂ is the occurrence interval of the occurrence to the time interval₁

Description: Time interval₂ extends from the start of the occurrence up to, but not including, the start

of the time interval₁.

Example: The rise of the human species to perpetuity.

occurrence to occurrence specifies time interval

Synonymous Form: <u>occurrence_1_to occurrence_2</u>

Synonymous Form: <u>time interval is occurrence</u>₁ to <u>occurrence</u>₂

Synonymous Form: <u>occurrence_until_occurrence_specifies time interval</u>

Synonymous Form: <u>occurrence_1 until occurrence_2</u>

Synonymous Form: <u>time interval</u> is <u>occurrence_1</u> until <u>occurrence_2</u>

Definition: the time interval is the occurrence interval of the occurrence₁ to the occurrence

interval of the occurrence2

Description: The <u>time interval</u> extends from the start of <u>occurrence_1</u> up to, but not including, the start

of occurrence₂.

Example: The contract signing to the contract termination.

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font

time interval is the duration preceding occurrence

Synonymous Form:

 $\frac{duration}{duration} \frac{duration}{duration} \frac{duration}{duration$ Definition: The <u>time interval</u> has the <u>duration</u> and is immediately before the <u>occurrence</u>. Description:

time interval is the duration following occurrence

Synonymous Form: duration following occurrence

Definition: time interval is the duration following the occurrence interval of the occurrence

Description: The <u>time interval</u> has the <u>duration</u> and is immediately after the <u>occurrence</u>.

16.7.2 Specifying time intervals using situation kinds

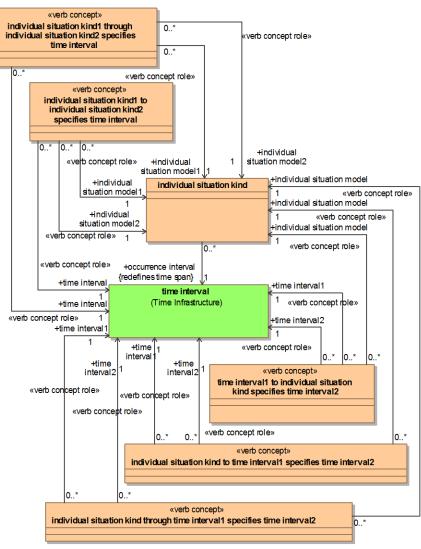

Figure 16.8 - Time intervals specified by situation kinds

time interval, through individual situation kind specifies time interval

Synonymous Form: <u>time interval_through individual situation kind</u>

Synonymous Form: <u>time interval_is time interval_1 through individual situation kind</u>

Synonymous Form: <u>individual situation kind_through time interval_1 specifies time interval_2</u>

Commented [EB117]: ty po,more in subclause

Formatted: Default Paragraph Font

Example:

Synonymous Form: <u>individual situation kind_through time interval_1</u>

Synonymous Form: time interval 2 is individual situation kind through time interval 1

Definition: the individual situation kind has exactly one occurrence and the time interval₂ is the

time interval₁ through the occurrence interval of the individual situation kind

Description: Time interval₂ extends from the start of time interval₁ through the end of the occurrence

of the individual situation kind.

Note: The definition is correct for both the individual situation kind' and 'individual situation

kind_through_timeinterval₁' forms.

Example: Primordiality through the rise of the human race.

Example: The coronation of Queen Elizabeth II through 1972.

individual situation kind, through individual situation kind, specifies time interval

Synonymous Form: individual situation kind through individual situation kind

Synonymous Form: time interval is individual situation kind, through individual situation kind,

Definition: the individual situation kind has exactly one occurrence and the individual situation

kind₂ has exactly one occurrence and the time interval is the occurrence interval of the individual situation kind₁ through the occurrence interval of the individual

situation kind₂

Description: The time interval extends from the start of occurrence of individual situation kind₁

through the end of the <u>occurrence</u> of <u>individual situation kind</u>₂.

The inception of a contract through the termination of the contract.

time interval, to individual situation kind specifies time interval

Synonymous Form: time interval₁ to individual situation kind

Synonymous Form: <u>time interval_2 is time interval_1 to individual situation kind</u>

Synonymous Form: <u>time interval_until individual situation kind specifies time interval_</u>

Synonymous Form: time interval_until individual situation kind

Synonymous Form: <u>time interval</u> is <u>time interval</u> until individual situation kind

Definition: the <u>individual situation kind</u> has exactly one <u>occurrence</u> and the <u>time interval</u>2 is the

time interval₁ to the occurrence interval of the individual situation kind

Description: <u>Time interval</u>2 extends from the start of <u>time interval</u>1 up to just before the <u>occurrence</u> of

individual situation kind.

Example: $\underline{2010}$ to the termination of employment.

individual situation kind to time interval, specifies time interval

Synonymous Form: <u>individual situation kind to time interval</u>

Synonymous Form: <u>time interval_is individual situation kind to time interval_1</u>

Synonymous Form: <u>individual situation kind until time interval</u>1

Synonymous Form: <u>individual situation kind until</u> time interval₁ is time interval₂

Definition: the individual situation kind has exactly one occurrence and the time interval is the

occurrence interval of the individual situation kind to the time interval

Definition: Time interval extends from the first occurrence of situation kind up to just before the

first <u>time interval_1</u>.

Example: Hiring to 2010.

individual situation kind, to individual situation kind, specifies time interval

Synonymous Form: individual situation kind₁ to individual situation kind₂

Synonymous Form: time interval is individual situation kind to individual situation kind

Synonymous Form: individual situation kind until individual situation kind specifies time interval

Synonymous Form: individual situation kind until individual situation kind

Synonymous Form: <u>time interval</u> is <u>individual situation kind</u> untilindividual situation kind

Formatted: Default Paragraph Font, Font: Bold

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font, Font: Bold

Formatted: Default Paragraph Font

Deleted:

Definition: the individual situation kind has exactly one occurrence and the individual situation

kind₂ has exactly one occurrence and the time interval is the occurrence interval of

the individual situation kind, to the occurrence interval of the individual situation

knd₂

Description: The time interval extends from the start of the occurrence of individual situation kind up

to, but not including, the occurrence of individual situation kind2.

Example: Hiring to termination.

16.8 Propositions, Situation Kinds, and Occurrences

The Date-Time Vocabulary builds on SBVR's <u>state of affairs</u> and related concepts. Clause 16.8.1 examines the relevant aspects of SBVR as background for clause 16.8.2, which discusses the truth of <u>propositions</u>, and for clause 16.8.3, which suggests how <u>situation kinds</u>, <u>occurrences</u>, and <u>states of affairs</u> should be used with verb concepts and verb concept objectifications.

16.8.1 'State of Affairs' in SBVR

The following glossary entries are excerpted from sub-clause 8.5 'Extensions' of SBVR. See the SBVR specification for the Notes, Examples, and other related material.

state of affairs

Definition: res that is an event, activity, situation, or circumstance

proposition corresponds to state of affairs

General Concept: 'meaning corresponds to thing'

Definition: the state of affairs is posited by the proposition and if the state of affairs were actual,

the proposition would be true

state of affairs is actual

Definition: the state of affairs happens (i.e., takes place, obtains)

actuality

Definition: state of affairs that is actual

SBVR sub clause 8.5.2 "Necessities Concerning Extension" defines several Necessities that are relevant to the Date-Time Vocabulary. Two of these are quoted verbatim here because an understanding of the relationship of states of affairs to time depends upon these constraints, and because the applicability of the second Necessity is narrowed by the Date-Time Vocabulary in this subclause.

Necessity: Each instance of a verb concept is an actuality.

Necessity: Each proposition that is true corresponds to exactly one actuality.

SBVR sub clause 8.5.2 also contains a Necessity that reads "Each proposition corresponds to exactly one state of affairs." As discussed below, this Necessity is unacceptable for the Date-Time Vocabulary because it requires a proposition such as "the United States elects a president" to correspond to only one state of affairs; i.e., only one event. The goal of the Date-Time Vocabulary is to provide concepts that are sufficient to represent real states of affairs, such as elections that occur multiple times. The Date-Time Vocabulary replaces this Necessity with a close alternative, "Each proposition corresponds to exactly one situation kind." This alternative is discussed in detail, below.

The Date-Time Vocabulary extends the concepts outlined above to address the following concerns.

 The Necessity "Each proposition corresponds to exactly one state of affairs" fails to acknowledge that many propositions correspond to states of affairs that recur. As stated in an Example in the state of affairs' glossary Commented [EB118]: ty po

Deleted: 2

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font

Formatted: Default Paragraph Font

entry in the SBVR specification, the <u>proposition</u> "EU-Rent owns 10,000 rental cars" *corresponds to* the <u>state of affairs</u> "EU-Rent owning 10,000 rental cars". The Necessity requires that this <u>state of affairs</u> only happens once. What if it happens in 2009 and also in 2012, but not in 2010 or 2011?

- 2. The same Necessity also interferes with verb concept objectifications. An example in clause 11.1.5.3 of the SBVR specification, under the glossary entry for 'general concept objectifies verb concept', reads "The general concept 'sponsorship' objectifies the verb concept 'company sponsors publication'. Each sponsorship is an actuality that a given company sponsors a given publication." The Necessity that a proposition corresponds to exactly one state of affairs means that there can be only one sponsorship. That contradicts the observed business situations, in which many real companies support multiple sponsorships.
- 3. Any proposition can be interpreted in two different ways: (i) as a possible state of affairs that may be planned, budgeted for, feared, considered, etc., and (ii) as an occurrence. For example, many building codes require builders to plan for the possibility of building fires, whereas fire departments fight actual fires. Possible fires may or may not be actual (in the sense of SBVR's 'state of affairs is actual' characteristic). Occurrences such as actual fires are actual if the universe of discourse contains current facts about them. Even future events (e.g., the election of a U.S. President in the years 2024 and 2028) are occurrences if they are facts ("propositions that are taken as true") at the current time.

The Date-Time Vocabulary addresses these concerns by building on the SBVR $\underline{\text{state of affairs}}$ concept as described in sub clause 16.8.2.

16.8.2 Propositions and States of Affairs

In a static world that has no notion of change, there is a 1-to-1 relationship between <u>propositions</u> and states of the possible worlds: A <u>proposition</u> is <u>true</u> if the state it describes is the state of that world, and it is false if the state it describes is not the state of that world. (The SBVR model of <u>states of affairs</u> reflects this model.)

When temporal concepts are introduced into the formal logic model, a distinction must be made between two aspects of the SBVR concept 'proposition'—the truth or falsity of the proposition, and a 'meaning' in terms of a situation. This is because many propositions correspond to a single situation (a 'situation kind') that may have multiple occurrences. Such propositions are also said to describe the occurrences of the situation kind. For example, the proposition "each payment must precede delivery" is an SBVR way to state an obligation about the sequencing of payment and delivery, as might be given in a BPMN process model. In a given possible world, there may be many occurrences of payment and delivery, and thus many occurrences of payment preceding delivery.

SBVR sub clause 8.1.2 says that a <u>proposition</u> is true if "the <u>state of affairs</u> that the <u>proposition</u> corresponds to is actual". The Date-Time Vocabulary specifies that each <u>proposition</u> corresponds to exactly one <u>situation kind</u>, and the <u>situation kind</u> has at least one <u>occurrence</u> that is current in the universe of discourse. This clause specifies what it means for a <u>situation kind</u> to <u>be actual</u>, and thus for the corresponding <u>proposition</u> to <u>be true</u>.

Necessity: Each <u>situation kind</u> is actual if and only if the <u>situation kind</u> has at least one

occurrence that is current.

Note: In SBVR, a <u>proposition</u> is true if it corresponds to a <u>state of affairs</u> that is actual. The

Necessity above establishes the basis for determining whether a proposition is true in a

given universe of discourse that contains time.

Note: The rule "Each factory manager must budget for situations where machines break down"

states an obligation with respect to a <u>situation kind</u> that is the <u>instance</u> of the <u>proposition</u> "machines break down". The <u>situation kind</u> may or may not turn out to <u>be actual</u> at some

time because the situation kind may or may not have any occurrences.

Each <u>proposition</u> may or may not reference time, and if it does reference time, then it may reference the past, the present, or the future. Regardless, a <u>proposition</u> is true if it corresponds to a <u>situation kind</u> that has an <u>occurrence</u> that is <u>current</u> in the universe of discourse. Each case is discussed and illustrated with an example, in the following text.

Most <u>propositions</u> do not mention time (i.e., are "atemporal"). For example, the <u>proposition</u> "the building is on fire" does not mention time. The truth of this example depends upon whether the proposition corresponds to an <u>occurrence</u> that <u>occurrence</u> in the universe of discourse. The <u>occurrence</u> may be directly given by a fact in the universe of discourse, or may be inferred from facts in the universe of discourse.

Some propositions are stated using past, present, or future tense, or contain explicit references to past time, current time, or future time. These propositions are true if and only if the universe of discourse contains facts ("propositions taken as true") that specify or imply current occurrences of the propositions. For example, the proposition "the contract was signed" is true if and only if there is an occurrence of "a signing of the contract" and that occurrence is in the past. The occurrence may exist as a fact or can be inferred from facts of the universe of discourse. Similarly, propositions about the present or the future are true if they exist as facts or are implied by facts of the universe of discourse. The proposition "the contract will expire" is a true proposition about the future if an occurrence of the proposition can be inferred from the facts of the universe of discourse.

<u>Propositions</u> may mention an explicit time, either as a <u>time coordinate</u> or as a definite description. For example, "an election is held in 2012" mentions the <u>time coordinate</u> "2012". The <u>proposition</u> "the contract will expire 2 years from the date the contract is signed" specifies a <u>time via a definite description</u>. Such <u>propositions</u> are true if the universe of discourse contains facts that specify or imply their <u>occurrence</u> – even if they are in the future.

Occurrences are actual if they are current:

Necessity: Each occurrence is actual if and only if the occurrence is current.

The Date-Time Vocabulary takes the position that <u>propositions</u> do not <u>correspond to occurrences</u>, even though <u>occurrence</u> is a specialization of <u>state of affairs</u>:

Necessity: It is not the case that some proposition corresponds to an occurrence.

When a proposition corresponds to a situation kind, the proposition describes any occurrences of the situation kind.

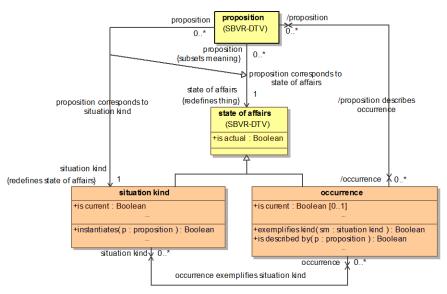

Figure 16.9 - Propositions, Situation Kinds, and Occurrences

proposition corresponds to situation kind

General Concept: proposition corresponds to state of affairs

Necessity: Each proposition corresponds to exactly one situation kind.

Note: In the Date-Time Vocabulary, the Necessity immediately above replaces the SBVR

Necessity "Each proposition corresponds to exactly one state of affairs".

Note: The instances of propositions are situation kinds which may or may not be actual.

The <u>instances</u> of <u>propositions</u> are <u>situation kinds</u>, which may or may not be <u>actual</u>. <u>Propositions</u> may be planned, feared, budgeted for, etc., whether or not they <u>correspond</u> to <u>situation kinds</u> that are <u>actual</u>. A <u>proposition</u> may refer to the past, present, or future without implying that the corresponding <u>situation kind</u> has been, is, or will be <u>actual</u>.

proposition describes occurrence

Definition: The proposition corresponds to a situation kind that has the occurrence.

Note: That is, the occurrence exemplifies the proposition in the sense of Plantinga (see [Menzel]).

Necessity: A proposition is true if and only if the proposition describes an occurrence that is

current.

Note: In a temporal world, the same <u>proposition</u> can describe several different <u>occurrences</u>,

even when all the <u>roles</u> in the <u>proposition</u> are played by exactly the same <u>things</u> in all <u>occurrences</u>. What distinguishes the <u>occurrences</u> are the things that are not mentioned in the proposition. In particular, a <u>proposition</u> that does not mention time may describe

different occurrences that have different occurrence intervals.

Example: Brazil wins the FIFA World Cup. That was true in 1994 and 2002, but false in 1992, 1998,

2006, and 2010. So the proposition "Brazil wins the FIFA World Cup" describes two

occurrences in the period 1992 to 2012.

Example: The proposition "Brazil won the FIFA World Cup in 1994" describes an occurrence that

is current in 2012. Thus, the proposition "Brazil won the FIFA World Cup in 1994" is

true in the world of 2012.

Possibility: A <u>proposition</u> <u>describes</u> zero or more <u>occurrences</u> (in a given possible world).

Possibility: An <u>occurrence</u> is described by zero or more <u>propositions</u>.

16.8.3 Verb Concepts, Verb Concept Objectification, and States of Affairs

The Date-Time Vocabulary distinction between <u>situation kinds</u> and <u>occurrences</u> enables verb concepts to be explicit about whether they range over potential <u>states of affairs</u> or real happenings. For example, an '<u>insures</u>' verb concept might be defined as '<u>person</u> insures against <u>situation kind</u>' to mean that the verb ranges over potential events, activities, situations, or circumstances. A '<u>reports</u>' verb concept might be specified as '<u>person</u> <u>reports</u> <u>occurrence</u>' to mean that what gets reported are real events, etc. One insures against fires that may never happen, but one should only report actual fires.

Business vocabularies should not define verb concepts that range over 'state of affairs' because the meaning is unclear.

SBVR sub clause 11.1.5.3 "Verb Concept Objectification" formalizes the idea that a general concept may be coextensive with a verb concept, the way many English gerunds (e.g., "planning") are coextensive with some verbs (e.g., "plan"). Verb concept objectifications that may or may not be *actual* should specialize either 'state of affairs' or 'situation kind'. Verb concept objectifications that are specifically about occurrences should specialize 'occurrence'.

Verb concept objectifications that specialize 'state of affairs' have the advantage that they may fill verb concept roles that range over 'stuation kind' and also verb concept roles that range over 'occurrence'. For example, the verb concept objectification 'machine breakdown' defined as 'state of affairs that machine is broken down' may be used with the verb concept 'manager plans for situation kind' and also with the verb concept 'manager reports occurrence'. With this approach, a single verb concept objectification can be used with slightly different meanings associated with each verb concept that ranges over the verb concept objectification. This is possible because both 'stuation kind' and 'occurrence' are specializations of 'state of affairs'. The advantage of this technique is that it better matches typical business English usage.

16.9 Language Tense and Aspect

As discussed in sub clause 7.12, human languages use past, present, and future tenses and incorporate simple, progressive, and perfect aspects. This sub clause provides concepts that enable all these tenses and aspects, in any combination. They extend the relationships between <u>situation kinds</u> <u>occurrences</u>, and time that are defined in this clause.

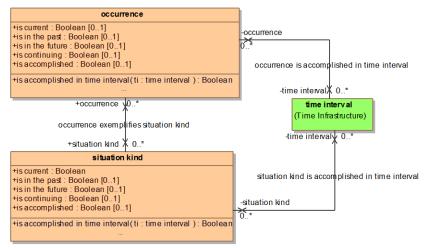

Figure 16.10 - Language Tense and Aspect

The following verb concepts formalize the progressive and perfect language aspects. The concepts are provided for both 'situation kind' and 'occurrence'; the former are normally used in guidance statements, while the latter are most useful in facts.

situation kind is continuing

Definition: the <u>situation kind</u> is unfinished at some reference time interval

Note: The reference time interval is when a fact is evaluated or a rule is being applied.

Note: 'situation kind is continuing' indicates the progressive aspect of natural language. It

is sometimes called the "continuous aspect."

Example: If company x is going bankrupt....

Note: 'Situation kind is continuing' is not the negation of 'situation kind is accomplished'

because a <u>situation kind</u> may end without being accomplished. Consider that the <u>situation kind</u> 'John writes book' in the partial rule "if John writes a book…" may end

without John ever completing the book

Note: A <u>situation kind</u> may be is continuing or is accomplished or both or neither, and may

also be in the past, present, or future tense. (See Table 16.1).

situation kind is accomplished

Definition: the <u>situation kind</u> has reached a point of completion or perfection at with respect to the

"reference time interval" associated with the concept 'time interval is past'

Note: The reference time interval is when a fact is evaluated or a rule is being applied.

Example: If company x has gone bankrupt....

Note: 'Situation kind is accomplished' is not the negation of 'situation kind is continuing'

because a $\underline{\text{situation kind}}$ may end without being accomplished. Consider that the

situation kind 'John writesbook' in the partial rule "if John writesa book..." may end

without John ever completing the book

A situation kind may be is continuing or is accomplished or both or neither, and may Note:

also be in the past, present, or future tense. (See Table 16.1).

situation kind is accomplished in time interval

Definition: the situation kind reaches a point of completion or perfection at some time interval2 that

is part of the time interval

Example: If the contract is completed within this year

occurrence is continuing

Definition: the occurrence is unfinished at some reference time interval

Note: The reference time interval is when a fact is evaluated or a rule is being applied.

'occurrence is continuing' indicates the progressive aspect of natural language. It is Note:

sometimes called the "continuous aspect."

Example: Company x is going bankrupt.

'Occurrence is continuing' is not the negation of 'occurrence is accomplished' Note:

because an occurrence may end without being accomplished. Consider that the occurrence 'John writes book' may end without John ever completing the book An occurrence may be is continuing or is accomplished or both or neither, and may also

be in the past, present, or future tense. (See Table 16.1).

occurrence is accomplished

Note:

Note:

Definition: the occurrence has reached a point of completion or perfection at with respect to the

"reference time interval" associated with the concept 'time interval is past'

The reference time interval is when a fact is evaluated or a rule is being applied. Note:

Example: Company x has gone bankrupt.

'Occurrence is accomplished' is not the negation of 'occurrences is continuing' Note:

because a state of affairs may end without being accomplished. Consider that the state of affairs 'John writes book may end without John ever completing the book An occurrence may be is continuing or is accomplished or both or neither, and may also

be in the past, present, or future tense. (See Table 16.1).

occurrence is accomplished in time interval

Definition: the occurrence reaches a point of completion or perfection at some time interval2 that is

part of the time interval

Example: The <u>occurrence</u> "Columbus reaches the new world" is accomplished in the 15th Century.

These verb concepts enable formulation of past, present, and future tense propositions. As above, the 'situation kind' versions of these concepts are most useful in guidance statements, while the 'occurrence' versions are intended for use in facts.

situation kind is in the past

Definition: the situation kind occurs throughout some time interval that is in the past

Example: If the customer has previously failed to pay his bill

Whether a situation kind is in the past may be inferred when a situation kind is located in Note:

time via any of the verb concepts given above, such as "situation kind is before

situation kind2."

situation kind is current

Definition: the situation kind occurs for some time interval that is current Example: "If the bill is currently due" (which might be formulated as "if the bill is due is current").

situation kind is in the future

Definition: the <u>situation kind</u> occurs throughout some <u>time interval</u> that is in the future

Example: "If President Obama will write his memoirs," which might be formulated as "If President

Obama writes his memoirs in the future."

Note: Whether a <u>situation kind</u> is in the future may be inferred when a <u>situation kind</u> is located

in time via any of the verb concepts given above, such as "situation kind is before

situation kind2."

occurrence is in the past

Definition: the occurrence occurs throughout some time interval that is in the past

Example: The reign of Alexander the Great is in the past.

Note: Whether an occurrence is in the past may be inferred when an occurrence is located in

time via any of the verb concepts given in this clause, such as "occurrence is before

occurrence2".

occurrence is current

Definition: the <u>occurrence</u> occurs for some <u>time interval</u> that is current

Example: That EU-Rent is in business is current (which means the same as "EU-Rent is currently in

business").

occurrence is in the future

Definition: the occurrence occurs throughout some time interval that is in the future

Example: "President Obama writes his memoirs" is in the future.

Note: Whether a state of affairs is in the future may be inferred when an occurrence is located

in time via any of the verb concepts given in this clause, such as "occurrence_1 is before

occurrence₂.

This specification defines vocabulary fact types in the present tense. Table 16.1 gives examples of how other tenses and aspects can be formulated. To show the range of expression supported by this vocabulary, some examples reference specific time intervals, while others leave unstated the time interval that an occurrence is continuing or is accomplished.

Table 16.1 assumes a domain vocabulary verb concept "John writes book". The examples are given as facts, and hence are formulated using the 'occurrence' version of the verb concepts listed above.

The text "(that <u>John</u> writes a <u>book</u>)" is short-hand for "the <u>proposition 'John</u> writes a <u>book</u>, corresponds to a <u>situation kind</u>". Nesting is used for some combinations. For example, "(that (that <u>John</u> writes a <u>book</u>) is in the future) is accomplished" means that the characteristic 'is accomplished is applied to a <u>situation kind</u> of "the characteristic 'is in the future', which itself is applied to a <u>situation kind</u> of the <u>proposition 'John</u> writes a <u>book</u>'".

Table 16.1 - Examples of tense and aspect formulation

ble 16.1 – Examples of tense and aspect formulation Simple Aspect				
Tense	Example	Formulation		
past	John wrote a book	(that <u>John</u> writes a <u>book</u>) is in the past		
present	<u>John</u> writes a book	<u>John</u> writes a book		
future	<u>John</u> will write a book	(that <u>John</u> writes a <u>book</u>) is in the future		
Progressive Aspect				
Tense	Example	Formulation		
past	John was writing a book	(that (that <u>John</u> writes a <u>book</u>) is continuing) is in the past		
present	<u>John</u> is writing a book	(that <u>John</u> writes a <u>book</u>) is continuing		
future	John will be writing a book	(that (that <u>John</u> writes a <u>book</u>) is continuing) is in the future		
		Perfect Aspect		
Tense	Example	Formulation		
past	John had written a book before 2009	(that (that <u>John</u> writes a <u>book</u>) is accomplished) occurs before 2009		
present	John has written a book	(that <u>John</u> writes a <u>book</u>) is accomplished		
future	John will have written a book by 2030	(that (that <u>John</u> writes a <u>book</u>) is accomplished) occurs before 2030		
Progressive and Perfect				
Tense	Example	Formulation		
past	John had been writing a book before 2009	(that (that <u>John</u> writes a <u>book</u>) is continuing) is accomplished) occurs before <u>2009</u>		
present	<u>John</u> has been writing a book	(that (that <u>John</u> writes a <u>book</u>) is continuing) is accomplished		
future	John will have been writing a book by 2030	(that (that <u>John</u> writes a <u>book</u>) is continuing) is accomplished) occurs before <u>2030</u>		

At the time of writing this document, the example "John will be writing a book during January 2021 through June 2022" is in the future. Nevertheless, the formulation includes the apparently redundant "is in the future" to express the future tense of the statement even after 2022.

The formulation of "John was writing a book last year" excludes "is in the past" because "last year" applies at all times.

Commented [EB119]: Issue 13-87 DELETE text

Deleted: <#>IndefiniteOccurrence Intervals¶

Indefinite occurrence intervals provide the basis for describing time intervals that extend indefinitely into the past or the future. One example is a British bond of the 1910s that pays interest "in

primordiality: fime interval

perpetuity: time interval

- Primordiality, Perpetuity, and Eternity

the time interval that is the occurrence interval of some occurrence, that begins before each occurrence. The time interval of the first occurrence.

This concept can be used in formulations such as "primordiality through current day" to define time intervals that began at some indefinite time in the past. Tools may choose to support a

convenient syntax such as "until <u>current day".</u>

'Primordialty' has a <u>duration</u> but it is not known.

'Primordialty' is an individual concept because there can be only one occurrence that begins before every occurrence.¶
"Primordally through Tuesday" meaning "until Tuesday".¶
perpetuity¶

the time interval that is the occurrence interval of some occurrence, that ends after each occurrence.

The time interval of the latest occurrence.¶
This concept can be used in formulations such as "2012 through

perpetuity" to define time intervals that extend indefinitely into the future. Tools may choose to support a convenient syntax such as "after 2012".¶

'Perpetuty' has a duration but it is not known.¶

'Perpetuty' is an individual concept because there can be only one

such occurrence.¶
"Contract signing through perpetuity" meaning "after the

contract signing".¶
elernity¶
lorever¶
The time interval that extends across the entire Ime Axis.¶ "Eternity" is an individual concept because there can be only one

such time interval.¶
'Eternity' is not the same thing as the Time Axis, even though it 'covers' the Time Axis.¶

17 Schedules (normative)

17.1 General

An important element of business activity and contracts is schedules: plans for situation kinds to occur at specific times.

Schedules Vocabulary

General Concept: terminological dictionary

Language: English

Included Vocabulary: Situations Vocabulary

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#Schedules Vocabulary

17.2 Schedules

Schedules model relationships between time intervals and situation kinds that are planned to occur at the time intervals. Time intervals of schedules can be sequential or overlapping, and at regular or irregular intervals. Schedules with non-overlapping sequential time intervals that repeat regularly are called regular schedules. Most mortgage loans call for payment according to regular schedules. Schedules with irregular time intervals are called ad hoc schedules. A conference schedule is usually ad hoc.

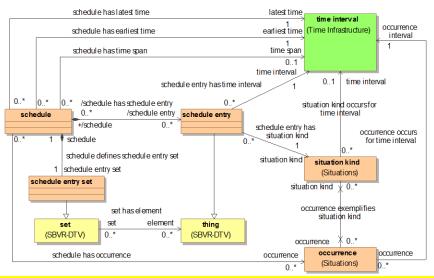

Figure 17.1 - Schedules

Deleted: 20150301

schedule

Definition: a plan for carrying out situation kinds at each of multiple time intervals

Each schedule is composed of an explicit (for <u>ad hoc schedules</u> and <u>schedule stubs</u> of <u>regular schedules</u>) or implicit (for <u>regular schedules</u>) set of <u>schedule entries</u>.

schedule entry

Definition: <u>proposition</u> that the <u>situation kind</u> happens on a <u>time interval</u>

Note: The <u>situation kind</u> should define its precise relationship with the time interval: whether the

situation kind occurs for, within, etc., the time interval.

schedule has schedule entry

Definition: the schedule entry is in the schedule entry set of the schedule.

CLIF Definition: (forall (s se

(iff ("schedule has schedule entry" s se)

(exists (ses) (and

("schedule entry set of schedule" ses s)

("thing is in set" se ses)))))

OCL Definition: context schedule

def: _'schedule has schedule entry'(se: _'schedule entry'): Boolean =

self._'schedule entry set'.includes(se)

schedule entry has situation kind

Necessity: Each schedule entry has exactly one situation kind.

CLIF Axiom: (forall (se) (exists (sk1)

(and ("schedule entry has situation kind" se sk1)

(forall (sk2)

 $(if ("schedule\ entry\ has\ situation\ kind"\ se\ sk2)$

 $(= sk1 \ sk2))))))$

OCL Constraint: context _'schedule entry'

inv: self._'situation kind'->size() = 1

schedule entry has time interval

Necessity: Each schedule entry has exactly one time interval.

CLIF Axiom: (forall (se) (exists (t1)

(iff ("schedule entry has time interval" se t1)

(forall (sk2)

(if ("schedule entry has time interval" se t2)

(= t1 t2))))))

OCL Constraint: context _'schedule entry'

inv: self._'time interval'->size() = 1

schedule entry set

Definition: <u>set</u> that is of 'schedule entry'

Necessity: Each schedule entry set includes at least one schedule entry.

CLIF Axiom: (forall (seset) (exists (se)

("schedule entry set includes schedule entry" seset se)))

OCL Constraint: context _'schedule entry set'

inv: self.includes->size()>0

schedule defines schedule entry set

Description: The <u>schedule entry set</u> is explicit in an <u>ad hoc schedule</u>, and implicit in a <u>regular</u>

schedule. The schedule entry set models the situation kinds and corresponding time

intervals of the schedule.

Note: This verb concept is refined, below, by 'regular schedule defines regular entry set'. 'Ad

hoc schedule' uses this verb concept as-is.

Necessity: Each schedule defines exactly one schedule entry set.

CLIF Axiom: (forall (se) (exists (ses)

(and ("schedule entry has schedule entry set" se ses)

(forall (ses2)

(if ("schedule entry has schedule entry set" se ses2)

(= ses1 ses2))))))

OCL Constraint: context _'schedule entry'

inv: self._'schedule entry set'->size() = 1

Schedules of all types share several attributes:

schedule has occurrence

Definition: the <u>occurrence</u> exemplifies the <u>situation kind</u> of a <u>schedule entry</u> of the <u>schedule</u>

and the <u>occurrence interval</u> of the <u>occurrence overlaps</u> the <u>time interval</u> of the

schedule entry

Note: The <u>occurrence</u> may be in the past or may be planned for the future.

CLIF Definition: (forall (s o)

))))

OCL Constraint: context schedule

inv: schedule._'time span'->size() = 1

Note: The verb concept 'occurrence occurs for time interval' can be used to say that an

 $\underline{occurrence} \ happens \ for \ the \ entire \ \underline{time \ span} \ of \ a \underline{schedule}.$

Example: A conference meeting might occur at a particular time interval of an ad hoc schedule,

while the entire conference occurs for the $\underline{time span}$ of the entire $\underline{schedule}$.

17.3 Regular Schedules

Regular schedules define a single situation kind that recurs at each time interval of the regular schedule. The verb concept 'regular schedule is for situation kind' means that the situation kind occurs at each time interval of the regular schedule.

This definition requires further extension to address what might be called 'complex regular schedules': regular schedules in which the scheduled time interval is defined according to a calendar to be one or more proper parts (rather than the

Commented [EB121]: ty pos: missing parens

whole) of the <u>recurrence duration</u>. For example, this definition does not support schedules such as or "the first Tuesday of each calendar month" or "the first and last calendar day of each calendar month".

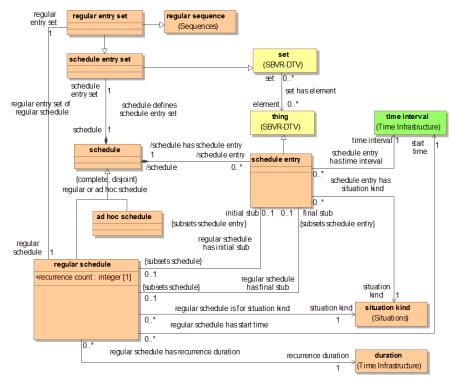

Figure 17.2 - Regular Schedules

regular schedule

Definition: schedule that a single situation kind occurs at the earliest time of the regular schedule,

and thereafter once each recurrence duration, for the recurrence count number of

recurrence durations, with optional initial stub and final stub

Necessity: No regular schedule is an ad hoc schedule.

CLIF Axiom: (forall ((rs "regular schedule")) (not ("ad hoc schedule" rs))

OCL Constraint: context _'regular schedule'

inv: not self.oclIsTypeOf(_'ad hoc schedule')

Example: A mortgage is payable monthly.

regular schedule is for situation kind

Synonymous Form: <u>situation kind</u> according to regular schedule

Synonymous Form: <u>situation kind has regular schedule</u>

Definition: the occurrence of each schedule entry of the regular entry set of the regular

schedule exemplifies the situation kind

Necessity: A regular schedule is for exactly one situation kind.

Commented [EB122]: ty po (unbalanced parens)

recurrence count

Synonym: repeat count

Concept Type: role

Definition: <u>number of occurrences of a regular schedule</u>

regular schedule has recurrence count

Definition: the recurrence count is the cardinality of the regular entry set of the regular

schedule

219

Formatted: Default Paragraph Font

Necessity: Each regular schedule has at most one recurrence count.

CLIF Axiom: (forall (rs rc1)

(if ("regular schedule has recurrence count" rs rc1)

(forall (rc2)

(if ("regular schedule has recurrence count" rs rc2)

(= rc1 rc2)))))

OCL Constraint: context _'regular schedule'

inv: _'regular schedule'._'recurrence count'->size() = 1
Note: This Necessity disallows unlimited regular schedules.

To support financial contracts, <u>regular schedules</u> may have an <u>initial stub</u> and/or a <u>final stub</u> that identify special situations that come before or after the schedule's repeating component. For example a home mortgage is payable monthly, at the start of each calendar month, for 30 years. Because the mortgage is finalized in the middle of a calendar month, an initial payment is due for the period up to the due date of the first monthly payment. Similarly, a final payment is due for several remaining days after the last monthly payment. The <u>initial stub</u> and <u>final stub</u> of a <u>regular schedule</u> can capture the details of these initial and final payments.

initial stub

Concept Type: role

General Concept: schedule entry

Description: An initial stub identifies special business treatment that should happen before the start of

the recurring portion of a regular schedule.

regular schedule has initial stub

Necessity: Each regular schedule has at most one initial stub.

CLIF Axiom: (forall (rs is1)

(if ("regular schedule has initial stub" rs is1)

(forall (is2)

(if ("regular schedule has initial stub" rs is2)

(= is1 is2)))))

OCL Constraint: context _'regular schedule'

inv: _'regular schedule'._'initial stub'->size() <= 1

final stub

Concept Type: role

General Concept: schedule entry

Description: A final stub identifies special business treatment that should happen after the end of the

recurring portion of a regular schedule.

regular schedule has final stub

Necessity: Each regular schedule has at most one final stub.

CLIF Axiom: (forall (rs fs1)

(if ("regular schedule has final stub" rs fs1)

(forall (fs2)

(if ("regular schedule has final stub" rs fs2)

(= fs1 fs2)))))

OCL Constraint: context _'regular schedule'

inv: _'regular schedule'._final stub'->size() <= 1

The following glossary entries "expand" 'regular schedule' to an implicit schedule entry set, including any initial stub and final stub. This enables the generic treatment (above) of regular schedules and ad hoc schedules.

regular entry set

Definition: schedule entry set that is a regular sequence

regular entry set of regular schedule

Definition: the cardinality of the regular entry set is the recurrence count of the regular schedule

and the situation kind of each schedule entry of the regular entry set is the situation kind of the regular schedule and the time interval of the first member of the regular entry set is the start time of the regular schedule and the time interval of the schedule entry that is next after a given schedule entry of the regular entry set is the recurrence duration of the regular schedule plus the time interval of the schedule

Description: The regular entry set is defined inductively as follows:

- The recurrence count specifies the number of schedule entries.

- Each schedule entry has the situation kind of the regular schedule.

- The first schedule entry has the start time of the regular schedule.

- The time interval of each subsequent entry is computed from the time interval of

the previous entry plus the recurrence duration.

Note: The following Necessity describes the construction of the (complete) schedule entry set of a regular schedule:

Necessity: The schedule entry set of a regular schedule is the regular entry set of the regular

schedule plus each initial stub of the regular schedule plus each final stub of the

regular schedule.

```
CLIF Axiom:
                           (forall (rs ses res)
```

```
(if (and
    ("regular schedule" rs)
```

("schedule defines schedule entry set" rs ses)

("regular schedule has regular entry set" rs res) (exists (init) ("regular schedule has initial stub" rs init)) (exists (fin) ("regular schedule has final stub" rs fin)))

(= ses (setplus (setplus res init) fin))

CLIF Axiom: (forall (rs ses res)

(if (and

("regular schedule" rs)

("schedule defines schedule entry set" rs ses) ("regular schedule has regular entry set" rs res) (exists (init) ("regular schedule has initial stub" rs init))

(not (exists (fin) ("regular schedule has final stub" rs fin))))

(= ses (setplus res init))

CLIF Axiom: (forall (rs ses res)

(if (and

("regular schedule" rs)

("schedule defines schedule entry set" rs ses) ("regular schedule has regular entry set" rs res)

(not (exists (init) ("regular schedule has initial stub" rs init))) (exists (fin) ("regular schedule has final stub" rs fin)))

(= ses (setplus res fin))

))

```
CLIF Axiom:

(forall (rs ses res)

(if (and

("regular schedule" rs)

("schedule defines schedule entry set" rs ses)

("regular schedule has regular entry set" rs res)

(not (exists (init) ("regular schedule has initial stub" rs init)))

(not (exists (fin) ("regular schedule has final stub" rs fin)))))

(= ses res)

))

OCL Definition:

context _'regular schedule'

inv: self_'schedule entry set' = self_'regular entry set'

.plus(self_'initial stub').plus(self_'final stub')
```

17.4 Ad Hoc Schedule

Ad hoc schedules associate a situation kind with each time interval because (in the general case) different events happen at each time interval.

ad hoc schedule

Definition: schedule that does not have a recurrence duration or a recurrence count

Note: An <u>ad hoc schedule</u> is a <u>set</u>, not a <u>sequence</u>, because the <u>time intervals</u> of the <u>ad hoc</u>

schedule may not be unique and may not be ordered.

Necessity: No ad hoc schedule is a regular schedule.

CLIF Axiom: (forall (ahs "ad hoc schedule")

(not ("regular schedule" ahs))

inv: not self.oclIsTypeOf(_'regular schedule')

Commented [EB123]: ty po: unbalanced parens

18 Interchange of Duration Values and Time Coordinates (normative)

18.1 General

The foregoing parts of this specification provide a formal terminology for expressing facts and rules involving time concepts in business communications. The expressions for time intervals that are commonly used in business communications are based on time coordinates, duration values, references to occurrences, and on the verb concepts defined in clause 8.2 and clauses 16 and 17. Further discussions of this can be found in Annex C.

Where those business communications are implemented by data exchanges, the terminology used in the formal exchange forms, such as XML, can be derived from the SBVR forms above, as specified in [SBVR] clause XXX, or from the corresponding UML model elements, as specified in [XMI].

The instances of <term>duration value</term> and <term>time coordinate</term>, and of the corresponding UML classes, however, have standard computational representations. The implementations of those concepts are said to be *datatypes*. This clause specifies the datatype representation of duration values and time coordinates in data exchanges.

Commented [EB124]: Issue 13-11 REPLACE text of clause

There are two significantly different standards for the representation of duration values and time coordinates:

- · ISO 8601 "Representation of dates and times", which standardizes character string representations
- IETF RFC 5905 "Network Time Protocol", which standardizes binary integer representations

To maximize compatibility with other standards, this specification proposes three compliance points:

- The XML Schema Compliance point requires support for the subset of ISO 8601 representations that is specified in [XML Schema Part 2 Datatypes]. Tools and documents that implement this compliance point can exploit the features of existing XML parsers and generators.
- The ISO 8601 Compliance point requires support for an extended subset of ISO 8601 that is sufficient to cover all of the duration value and time coordinate concepts specified in clauses 9, 11, 12, and 13 of this specification. Tools that implement this compliance level can use standard XML parsers and generators for the datatypes defined by XML Schema, but must implement additional support as described in sub clause 18.1.
- The Internet Time Compliance point requires support for the representations of duration values and time coordinates
 that are specified in IETF RFC 5905. These forms should be used for time-critical applications in which
 calculations of durations and comparisons of time coordinates are intrinsic to aspects of the application.

These compliance points are further detailed below. This specification recommends the use of ISO 8601 forms (and related standards) for most business purposes.

18.2 Datatype representation of duration values

IISO 86011 clause 4.4.3 defines a lexical representation for duration values as a component of time intervals. IXML Schema Part 21 defines a datatype named "duration" to represent duration values in XML documents. The XML Schema representation is compatible with ISO 8601 for representing duration values whose time unit is year, month, day, hour, minute, or second, or some combination thereof. ISO 8601 specifies a similar representation for duration values whose time unit is week, but those representations are not permissible values of the XML Schema datatype 'duration'.

XML Schema Compliance Point

Implementations of the XML Schema Compliance Point shall implement all of the duration value representations that are valid values of the XML Schema datatype 'duration'. The requirement for representations in these forms applies to all exchanges, not just XML-based exchanges.

The XML Schema Part 2 clause 3.2.6.2 "Order Relation on Duration" does not apply to representations of duration values. This specification describes a more comprehensive approach to ordering of duration values based on duration value sets, and mandates that interpretation of ordering for duration values. Therefore, implementations should not rely on standard XML software libraries for the order relation on "duration".

Tools that only implement this compliance point should convert duration values given in Weeks to equivalent values given in days.

ISO 8601 Compliance Point

Implementations of the ISO 8601 Compliance point shall support all valid values of the XML Schema datatype 'duration'. In addition, implementations of this compliance point shall implement representation of duration values that include the time unit 'week' using the general form "PnYnWnDTnHnMnS", where the term "nW" denotes a duration value whose time unit is 'week'. In this representation, the year, day, and time of day components must conform to the rules defined in XML Schema Part 2 clause 3.2.6.1 for number of digits, value range, use of leading minus sign, reduced precision, and truncation. The number of weeks must be greater than 1. If the number of years, days, hours, minutes, or seconds equals zero, the number and corresponding designator may be omitted. Thus, the following examples are all legitimate:

P3W -- three weeks
P3W4D -- three weeks and 4 days

```
P1Y3W4D -- 1 year and 3 weeks and 4 days
P1Y3W4DT5H -- 1 year and 3 weeks and 4 days and 5 hours
```

XML elements that are used to interchange duration values that may include the 'week' time unit should have the "extendedDuration" XML element type defined as:

Conforming tools shall accept all 'duration' values as valid values of this "extendedDuration" type. Conforming tools shall also accept the standard XML Schema "duration" datatype as a representation for duration values.

Internet Time Compliance Point

Implementations of the Internet Time Compliance Point shall represent all duration values as 64-bit integer multiples of the base time unit for Internet Time (equal to 2^-32 seconds, approximately 200 picoseconds), as specified in IETF RFC 5905. The actual representation of the (nominally binary) integer value depends on the nature of the exchange specification (e.g., JSON vs. XML).

18.3 Datatype representation of time coordinates

Table 18.1 below shows all of the time coordinate types that are defined in this specification, and the corresponding time coordinate format specifications from ISO 8601 and XML Schema Part 2 Datatypes. Where both standards specify a representation for the same time coordinate type, the XML Schema form is identical to the ISO 8601 form. The XML Schema forms for the additional time coordinate types it supports are consistent with the overall approach in ISO 8601. In a similar way, this specification mandates the ISO 8601 forms and the XML Schema datatypes that support time coordinates specified herein, and extends the representation set in a way that is consistent with the ISO 8601 approach.

XML Schema Compliance Point

Implementations of the XML Schema Compliance Point shall implement all of the time coordinate representations that are valid values of the XML Schema datatypes specified in Table 18.1. The requirement for representations in these forms applies to all exchanges, not just XML-based exchanges.

The XML Schema Part 2 clause 3.2.7.4 "Order Relation on dateTime" does not apply. This specification describes a more comprehensive approach to ordering of time coordinates based on time sets, and mandates that interpretation of ordering for time coordinates. Therefore, implementations should not rely on standard XML software libraries for the order relation on "dateTime".

For tools that conform only to this compliance point, the handling of time coordinates that have no XML Schema form is not specified. No support for such time coordinates is required, although conversion of Gregorian year day coordinates to Gregorian year month day coordinates is recommended.

able 18.1 - Relationship between Date-Time time coordinates and standard forms				
category of time coordinate	ISO 8601 type	XML Schema datatype		
date time	date and time of the day (4.3)	<u>dateTime</u>		
time of day coordinate	time of the day (4.2 generally)	<u>time</u>		
Gregorian year month day coordinate	Calendar date (complete representation 4.1.1.1)	<u>date</u>		
Gregorian year month coordinate	Calendar date (reduced precision 4.1.1.2 a)	<u>gYearMonth</u>		
Gregorian year coordinate	year (reduced precision 4.1.1.2 b)	gYear		
Gregorian month day coordinate	Calendar date (truncated representation 4.1.1.3 d)	gMonthDay		
Gregorian month coordinate	month (truncated representation 4.1.1.3 e)	gMonth		
Gregorian day of month coordinate	day of the month (truncated representation 4.1.1.3 f)	gDay		
Gregorian day of year coordinate	day of the year (truncated representation 4.1.3.2 b)			
Gregorian year day coordinate	Ordinal date (complete representation 4.1.3.1)			
ISO day of week coordinate	week date (truncated representation 4.1.4.3 g)			
ISO week of year coordinate	calendar week (truncated representation 4.1.4.3 f)			
ISO week day coordinate	week date (truncated representation 4.1.4.3 e)			
ISO year week coordinate	week date (reduced precision 4.1.4.2)			
ISO year week day coordinate	week date (complete representation 4.1.4.1)			

ISO 8601 Compliance Point

Implementations of the ISO 8601 Compliance point shall support all valid values of the XML Schema datatypes that appear in Table 18.1. In addition, implementations of this compliance point shall support the additional representations for the time coordinate types listed below. These additional lexical representations are, or are variants of, the formats already defined in ISO 8601. The design goal is to build upon ISO 8601 in as simple a manner as possible.

Table 18.2 specifies lexical representations for time coordinate types that are not supported by XML Schema datatypes. Several of these representations are specified in ISO 8601, as shown in the table. Tools shall generate and/or accept these representations using the "Extended format" described in ISO 8601.

In the representation formats specified in Table 18.2,

- "yyyy" represents a year number that should have four digits;
- "ddd" is a one- to three-digit number that indicates the day within the year (the 'day of year');
- "W" is the character 'W' the week designator;
- "ww" is a one- or two-digit number that indicates te ISO week of year;
- "d" is a single-digit that indicates the ISO day of week number (where 1 represents Monday).

Table 18.2 - Interchange Representations for Time Coordinates

Table 10.2 - Interchange Representations for Time Coordinates				
time coordinate type	Lexical Representation	<u>Source</u>		
Gregorian year day coordinate	yyyy-ddd	[ISO 8601] clause 4.1.3		
ISO year week coordinate	yyy-Www	[ISO 8601] clause 4.1.4		
ISO year week day coordinate	yyyy-Www-d	[ISO 8601] clause 4.1.4		
Gregorian day of year coordinate	<u>ddd</u>	[ISO 8601] clause 4.1.3		
ISO day of week coordinate	<u>W-d</u>	[ISO 8601] clause 4.1.3		
ISO week of year coordinate	Www	[ISO 8601] clause 4.1.3		
ISO week day coordinate	<u>Www-d</u>	[ISO 8601] clause 4.1.3		

An ISO day of week coordinate is represented by the week designator "W" (without an ISO week number), followed by one dash, followed by a single ISO day of week number.

An ISO week of year coordinate is represented by the week designator "W", followed by a one- or two-digit ISO week of year number.

An ISO week day coordinate is represented by the week designator "W", followed by a one- or two-digit ISO week of year number, followed by one dash and a single-digit ISO day of week number.

XML elements that are used to interchange time coordinates that may have any of the formats listed in Table 18.2 should have the "extendedDateTime" XML element type defined as:

<xs:simpleType name="extendedDateTime" >
 <xs:restriction base="xs:string"/>

</xs:simpleType>

<xs:element name="extendedDateTime" type="extendedDateTime"/>

Conforming tools shall accept all 'dateTime' values as valid values of this "extendedDateTime" type. Conforming tools shall also accept the standard XML Schema "dateTime" datatypes as representations for the corresponding time coordinate types.

Internet Time Compliance Point

Implementations of the Internet Time Compliance Point shall represent all absolute time coordinate instances as an amount of time since midnight, January 1, 1900. The amount of time is a duration value and shall be represented in the Internet Time form for duration values (see 1.2).

Internet Time cannot be used to represent any relative time coordinate. Internet Time cannot be used to represent any time point prior to January 1, 1900.

Implementations that support the Internet Time Compliance Point are encouraged to implement one of the other compliance points for more general uses of time coordinates.

Deleted: The Date-Time RFP requests "... a text format for exchanging date and time literals in SBVR interchange files, OWL ontologies, UML models, etc." and goes on to suggest that it should be "based on ISO 8601 as applied in XML Schema." This clause responds to that requirement by specifying how SBVR tools should exchange duration values and time coordinates. This clause assumes that tools will interchange vocabularies using XMI as defined in [SBVR] sub clause 13.6. ¶

This clause is applicable when one tool that supports this Date-Time

This clause is applicable when one tool that supports this Date-Time Vocabulary transmits a vocabulary to another such tool. This clause is normative for SBVR tools and informative for OWL, CL, UML, or other tools.

[XML Schema] Part 2 defines a dataty pe named "duration" to represent in XML files what this specification calls — duration values. [ISO 8601] defines a lexical representation for durations only as a component of time intervals ([ISO 8601] clause 4.4.3), and [XML Schema] is compatible with it for representing years, months, days, hours, minutes, and seconds. [ISO 8601], but not [XML Schema], supports weeks [ISO 8601], [ISO 8601], but not [XML Schema] defines the dataty results of in Table 18. [II]

[XML Schema] defines the dataty pes listed in Table 18.1¶ to represent various ty pes of time coordinates. The [XML Schema] lexical representation of these is based on [ISO 8601] but goes bey ond [ISO 8601] by defining formats for ← relative time coordinates such as Gregorian month day

oordinate.¶

Annex C - Business Usage Guidelines

(informative)

Annex C is now published as a separate document: http://www.omg.org/spec/DTV/20150301/dtv-guidelines.pdf.

Annex D - Fundamental Concepts

(normative)

D.1 General

International standards, for example [VIM], [ISO 80000:3], and [ISO 18026] define <u>duration</u> as just one of many <u>quantity kinds</u>, and <u>time scales</u> as one of many kinds of <u>coordinate systems</u>. This permits the formation of <u>derived quantities</u> based on <u>durations</u> (e.g., velocity, which is length / <u>duration</u>), and multi-dimensional <u>coordinate systems</u> that include time as one dimension. <u>Coordinate systems</u> themselves depend upon mathematical concepts, such as <u>sequences</u>. The axioms related to <u>time intervals</u> depend upon mereology concepts.

Unfortunately, there is no existing SBVR vocabulary or ODM ontology that addresses these concepts. The authors recognize that they are out-of-scope for this specification, but felt it necessary to imagine how this Date-Time Vocabulary would fit into a complete schema that addresses them. Annex D summarizes that schema in the form of several SBVR vocabularies

There are a few existing OMG efforts covering this topic that are referenced in Annex B. The most recent of these is [QUDV], but it models the concept 'quantity' differently than here because of limitations of UML and SysML. In particular, QUDV does not model the distinction between 'quantity' and 'quantity value.'

There is one external group [QUOMOS] that is working in this area, and that is proposed as an OASIS Technical Committee effort called "Quantity and Unit of Measure Ontology Standard (QUOMOS)." As and when [QUOMOS] reaches completion, the contents of this section should be reviewed for possible alignment with [QUOMOS].

Subclauses D.2 "Sequences" and D.4 "Mereology" are complete and consistent models of their topics and are normative.

Subclause D.3 "Quantities Vocabulary" is informative because it addresses only the aspects of <u>quantities</u> and <u>units of measure</u> that are required by the Date-Time Vocabulary, and because the other groups mentioned above have the charter to fully address the topic.

D.2 Sequences (normative)

The 'sequence' concept models ordered collections of things in which the things are ordered by assigning numbers (indices) to them within the collection, as distinct from any particular properties of the things themselves. The model does not preclude the use of properties in creating indices, and it does not require the indices to be consecutive in the general case.

Regular sequences provide the mathematical foundation of time scales.

There are two somewhat different models of <u>sequence</u> that are in common use. Using UML terminology, we may call them the "composite model" and the "aggregation model." In the composite model, the existence and conceptualization of the <u>member</u>s is dependent on the existence and conceptualization of the <u>sequence</u>. In these <u>sequences</u>, the <u>index</u> of a <u>member</u> is intrinsic to the <u>member</u> – its meaning is bound up with its position in the <u>sequence</u>. This is the case with time concepts like <u>months of year</u> or <u>hours of day</u>: <u>2:00</u> is the <u>hour of day</u> that occurs immediately after <u>1:00</u>; its definition depends on the <u>sequence</u>.

In the aggregation model, the <u>members</u> of the <u>sequence</u> have independent existence, with intrinsic properties that are independent of the <u>sequence</u>. The <u>sequence</u> conceptualizes (and imposes) an ordering on the <u>members</u> that is not intrinsic to the <u>members</u> themselves. In these <u>sequences</u>, the <u>indices</u> of the <u>members</u> are extrinsic – the <u>member</u> acquires the <u>index</u> by being included in the <u>sequence</u>, and it can have other <u>indices</u> in other <u>sequences</u>. In some such <u>sequences</u>, a given <u>member</u> can occur more than once. A common example is a list of authorized suppliers in order of preference or total order volume. Similarly, <u>time intervals</u> exist without clocks, and although they are intrinsically ordered, they only acquire <u>indices</u> when we impose a standard clock and a <u>time offset</u> on them.

The model presented here is general enough to support both models, but each actual sequence will use it differently, depending on the nature of its members. The model below distinguishes between the things that are by definition elements of the sequence – the sequence positions – and things that exist independently and are ordered by the sequence – the members. Time scales, such as clocks and calendars, are defined to be sequences whose members are time points, such as 'hour of day'. The sequence positions of each time scale (sequence) have indices that are used to number the time points that are their members. The application of time scales to the time Axis, causes the assignment of time intervals as instances of the time points. Thus, one time interval in each day is an instance of the 'hour of day' with index 12, i.e., 12 o' clock.

Sequences Vocabulary

General Concept: terminological dictionary

Language: English

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#SequencesVocabulary

D.2.1 General Sequence Concepts

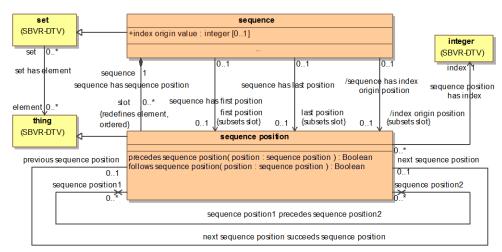

Figure D.1 - Sequences

sequence

Note:

Definition:

set whose elements are ordered by their indices

"Sequence" is a conceptual mechanism for ordering things. A sequence is made up of sequence positions (slots), each of which may have a member. These members are the things that participate in the sequence. For convenience, the things that are the members of the sequence positions of a sequence are also called the members of the sequence.

Note: In the general case, a given thing may participate in a sequence more than once, i.e., as

more than one member of the same sequence. See 'regular sequence' for a kind of sequence where a thing is constrained to participate at most once in the sequence.

Each sequence defines an ordering on its sequence positions, by assigning an integer index to each sequence position, and using the ordering of the integers to order the members. The index assignment may be based on some natural characteristics of the members, or it may be just sequential position numbers, or it may be some other numbering scheme associated with the meaning of the sequence. In general, the index

assignments need not reflect any natural ordering of the members. That is, the ordering of the members of a sequence can be specific to the sequence concept.

sequence position

Note:

Synonym: slot

Definition: element of a given sequence

Note: A sequence is a set of sequence positions. Each sequence position is an element of

the sequence that defines it, and no other.

Each sequence position has an integer index associated with it. The ordering on the Note:

sequence is induced on it by the natural ordering of the integers.

sequence has sequence position

Synonymous Form: sequence position in sequence

Each sequence position is of exactly one sequence. Necessity:

CLIF Axiom: (forall (seq sp)

(if ("sequence has sequence position" seq sp)

(and

(sequence seq)

("sequence position" sp)

(forall (seq2)

(if ("sequence has sequence position" seq2 sp)

(= seq2 seq))))))

Possibility: Some sequence has no sequence positions.

This verb concept is a specialization of SBVR's 'thing is in set.' Note:

index

Synonym: indices Concept Type: role General Concept: integer

The basis for assigning a particular index to a given sequence position might be a Note:

characteristic of the member of the sequence position (such as weight, etc.). This technique would order the members by weight, or inversely by weight, depending on the

index assignments.

Note: Negative indices are meaningful for time scales of years that extend before year zero.

sequence position has index

Synonymous Form: index indexes sequence position

Definition: the index is assigned to the sequence position and is used in ordering the

sequence positions in the sequence

Each sequence position has exactly one index. Definition:

If the index₁ of some sequence position₁ of some sequence equals the index₂ of Necessity:

some sequence position, of the sequence then sequence position, is sequence

position₂.

```
CLIF Axiom:
                          (forall (seq sp1 sp2 x1 x2)
                           (if
                             (and
                               ("sequence has sequence position" seq sp1)
                               ("sequence has sequence position" seq sp2)
                               ("sequence position has index" sp1 x1)
                               ("sequence position has index" sp2 x2)
                               (= x1 x2))
                            (= sp1 sp2)))
                          (forall ((sp "sequence position"))
CLIF Axiom:
                            (exists ((x1 "integer"))
                             (and
                               ("sequence position has index" sp x1)
                               (forall (x2)
                                (if
                                 ("sequence position has index" sp x2)
                                 (= x1 x2))))))
OCL Constraint:
                          context sequence:
                               inv: self._'sequence position'->forAll(sp1 |
                                   self._'sequence position'->forAll(sp2 |
                                   indexOf(sp1) = indexOf(sp2) implies sp1 = sp2))
```

sequence position₁ precedes sequence position₂

Synonymous Form: <u>sequence position</u>₂ follows <u>sequence position</u>₁

Definition: the index of sequence position, is less than the index of sequence position.

CLIF Definition: (forall (sp1 sp2 x1 x2)

(if (and

> ("sequence position has index" sp1 x1) ("sequence position has index" sp2 x2))

(iff ("sequence position1 precedes sequence position2"

sp1 sp2) (exists ((seq_sequence))

(and

("sequence has sequence position" seq sp1) ("sequence has sequence position" seq sp2)

(< x1 x2))))))

Note: This is the ordering relation on the sequence positions.

next sequence position

Definition: <u>sequence position that succeeds a given sequence position</u>

General Concept: <u>sequence position</u>

Concept Type: role

Note: In a <u>finite sequence</u>, the <u>last position</u> does not have a <u>next sequence position</u>.

next sequence position succeeds sequence position

Synonymous Form: next sequence position is next after sequence position sequence position is just before next sequence position is just before next sequence position

Synonymous Form: <u>sequence position</u> has <u>next sequence position</u>

Definition: next sequence position follows sequence position and the index of next sequence

position is less than or equal to the index of each sequence position that follows

sequence position.

Necessity: Each sequence position has at most one next sequence position.

CLIF Definition: (forall (sp nsp) (iff ("next sequence position succeeds sequence position" ("sequence position1 precedes sequence position2" sp nsp) (not (exists (sp2) (and ("sequence position1 precedes sequence position2" sp sp2) ("sequence position1 precedes sequence position2" sp2 nsp))))))) OCL Definition: context _'sequence position' inv: self._'sequence position1 precedes sequence position2' (self._'next sequence position') and self._'sequence position2'->forAll(sp2 | self._'next sequence position'.index <= sp2.index)

first position

Concept Type: role

General Concept: sequence position

sequence has first position

Definition: the index of the first position is less than or equal to the index of each sequence

position in the sequence

Necessity: Each sequence has at most one first position.

Possibility: A sequence has no first position.

Necessity: No sequence position precedes the first position of each sequence.

last position

Concept Type: role

General Concept: sequence position

sequence has last position

Definition: the index of the last position is greater than or equal to the index of each sequence

position in the sequence

Necessity: Each sequence has at most one last position.

Possibility: A sequence has no last position.

Necessity: No sequence position succeeds the last position of each sequence.

D.2.2 Sequence Members

This sub clause extends the <u>sequence</u> model to accommodate situations in which the <u>sequence position</u> itself is artificial – it represents the role of some <u>thing</u> that exists independently from the <u>sequence</u>.

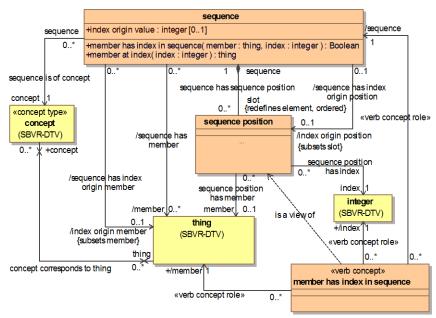

Figure D.2 - Sequence Members

member

Concept Type: role
General Concept: thing

Definition: thing that is in a given sequence position, and by extension, any thing that participates

in a given sequence

sequence position has member

Synonymous Form: <u>stot contains member</u>

Synonymous Form: member is in sequence position
Synonymous Form: member in sequence position

Necessity: Each sequence position has at most one member.

Possibility: A sequence position has no member.

Possibility: Each thing is the member of zero or more sequence positions in zero or more

<u>sequences.</u>

Note: For some sequences, the sequence positions have meaning in their own right, and

may or may not have members. For example, the meaning of a scale point is a

quantity.

member participates in sequence

Synonymous Form: Sequence has member member of sequence
Synonymous Form: member in sequence

member in sequence

Definition: the <u>member</u> is the <u>member</u> of a <u>sequence position</u> of the <u>sequence</u>

CLIF Definition: (forall ((s sequence) (member thing)) (iff ("sequence has member" s member) (exists ((sp "sequence position")) (and ("sequence has sequence position" s sp) ("sequence position has member" sp m))))) OCL Definition: context sequence def: _'member participates in sequence' (member: thing, s: sequence) : Boolean = self._'sequence position'->exists(sp | sp.member = member) Things are assigned as members of a sequence to induce a desired ordering relation Note: among the things. Thus, a given set of things may be ordered differently in different sequences by their weight, height, arrival time in a queue, service priority, etc. member has index in sequence Synonymous Form: sequence has member with index The sequence has a sequence position that has an index that equals the index, and Definition: the sequence position has a member that is the member. CLIF Definition: (forall (member index s) (iff ("member has index in sequence" member index s) (and (sequence s) (integer index) (exists (sp) (and ("sequence has sequence position" s sp) ("sequence position has index" sp index) ("sequence position has member" sp member)))))) OCL Definition: context sequence def: _'member has index in sequence' (member: thing, i: integer, s: sequence) : Boolean = self._'sequence position'->exists(sp | sp.index = index and sp.member = member) Note: This verb concept states that in a given sequence the position that is given by the index is occupied by the member. A given thing can have zero, one, or more than one indices in a thing has more than one index in the same sequence. Possibility: Note: The primary verb concept wording and the synonymous form given above are "sentential forms". Following the conventions described in clause 6, the corresponding CLIF predicate and OCL operation yield a Boolean result. In addition, this verb concept has a "noun form" (member with index in sequence), for which the corresponding CLIF and OCL functions return the thing that plays the member role in the relationship. Synonymous Form: member with index in sequence The Synonymous Form given above is an SBVR "noun form" that yields a member given an index and a sequence. CLIF Definition: (forall (member index s) (iff (= member ("member with index in sequence" index s)) ("member has index in sequence" member index s))) OCL Definition: context sequence def: _'member with index in sequence' (index: integer, s sequence): thing =

self._'sequence position'->select(sp | sp.index = index).member

sequence is of concept

Definition: the concept corresponds to each member of the sequence

CLIF Definition: (forall (s c)

(iff ("sequence is of concept" s c) (and

(sequence s) (concept c) (forall (member)

(if ("member participates in sequence" member s) ("meaning corresponds to thing" c member)))

)))

OCL Definition: context sequence

def: _'sequence is of concept'(c: concept)

: Boolean =

sequence._'sequence position'.member->forAll(m | 'concept corresponds to instance'(c m))

Each sequence is of at least one concept. Necessity:

Note: Constraints based on the verb concept 'sequence is of concept' limit each member to be

an instance of the concept. If more than one such constraint is stated for the same

sequence, every member must satisfy all such constraints.

Note: Such constraints can be relaxed as needed by specifying that a sequence is of any

convenient more general concept of the members of the sequence. Since the concept 'thing' is a more general concept of all other object types, a sequence that 'is of thing'

permits members of any type.

D.2.3 **Index Origin**

index origin member

Concept Type:

Definition: member that is assigned the index that is the index origin value

Note: This is a primitive definition. Either 'index origin member' or 'index origin value' must

be defined in terms of the other.

For <u>sequences</u> that have a <u>first member</u>, the <u>first member</u> is usually designated as the Note:

index origin member. In a sequence that has no first member, the index origin member is usually determined by association to some real world event or property. The <u>member</u> with <u>index 1875</u> (the year of the <u>Convention du Mètre</u>) is the <u>index origin</u>

member of the Gregorian years scale.

index origin value

Example:

Concept Type: role General Concept: integer

The index origin value is most commonly either 0 or 1. Note:

Example: The first member of time scales of hours, minutes, and seconds has index origin value 0

because these are counted from 0 by convention.

Example: The first member of time scales of years, months, weeks, and days has index origin value

1 because these are counted from 1 by convention.

index origin position

Concept Type: role

General Concept: sequence position

sequence has index origin member

Definition: The index origin member of the sequence is the member of the index origin position

of the sequence.

Necessity: Each sequence has at most one index origin member.

CLIF Axiom: (forall (seq) (forall (iom)

(if ("sequence has index origin member" seq iom)

(and (forall (m)

(if ("sequence has index origin member" seq m)

(= m iom)))))))

OCL Constraint: context sequence

inv: sizeOf(self. 'index origin member') <= 1

Commented [EB125]: Issue 13-65 INSERT text

sequence has index origin value

Necessity: Each sequence has at most one index origin value.

CLIF Axiom: (forall (seq) (forall (iov)

(if ("sequence has index origin value" seq iov)

(and (integer iov) (forall (iv2)

(if ("sequence has index origin value"

seq iv2) (= iov iv2)))))))

OCL Constraint: context sequence

inv: sizeOf(self._'index origin value') <= 1

Commented [EB126]: Issue 13-65 Replace text

Deleted: exists

Commented [EB127]: Issue 13-65 INSERT text

sequence has index origin position

Necessity: Each sequence has at most one index origin position.

Necessity: The index of the index origin position equals the index origin value of the sequence.

CLIF Axiom: (forall (s p)

(iff ("sequence has index origin position" s p)

(exists (iov) (and

("sequence has index origin value" s iov) ("sequence position has index" p iov)))))

OCL Constraint: context sequence

inv: sequence._'index origin value' =

sequence._'index origin position'.index

D.2.4 Kinds of Sequences

This clause defines various sequence types in order to clarify the distinctions among and meaning of each type.

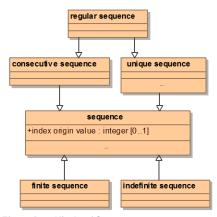

Figure D.3 - Kinds of Sequences

consecutive sequence

```
Definition:
                           sequence that each sequence position of the sequence that is not the first position
                           of the sequence is next after a sequence position, and the index of the sequence
                           position equals 1 plus the index of the sequence position2
Description:
                           A consecutive sequence is a sequence in which consecutive sequence positions have
                           consecutive indices.
CLIF Definition:
                           (forall (s) (iff ("consecutive sequence" s)
                                (and
                                  (sequence s)
                                  (forall (sp1 sp2 x1 x2)
                                   (if
                                    (and
                                     ("sequence has sequence position" s sp1)
                                     ("next sequence position succeeds sequence position"
                                           sp2 sp1)
                                      ("sequence position has index" sp1 x1)
                                     ("sequence position has index" sp2 x2))
                                    (= x2 (+ x1 1)))
                               )))
OCL Definition:
                          context _'consecutive sequence'
                          inv: self._'sequence position'->forAll(sp |
                              not (self._'first position'->exists()
                                and sp = self._'first position')
implies self._'sequence position'.indexOf(sp) =
                                 1 + self._'sequence position'
                                    ->indexOf(sp._'previous sequence position'))
Note:
                           In a consecutive sequence, the indices of the members are consecutive integers.
```

unique sequence

Definition: sequence that has no member that is the member of more than one sequence

position of the sequence

```
CLIF Definition:
                              (forall (s)
                              (iff ("unique sequence" s)
                               (and
                                 (sequence s)
                                 (forall (sp1 sp2 t1 t2)
                                  (if
                                    (and
                                     ("sequence has sequence position" s sp1)
                                     ("sequence has sequence position" s sp2)
                                     ("sequence position has member" sp1 t1)
                                     ("sequence position has member" sp2 t2)
                                     (not (= sp1 sp2)))
                                   (not (= t1 t2)))))))
    OCL Definition:
                              context sequence
                              inv: self.member->forall(m |
                                   self\_'sequence\ position'.member->isUnique\ (m2 \mid m=m2))
    Necessity:
                              Each thing has at most one index in each unique sequence.
    CLIF Axiom:
                              (forall (thing (x1 integer) (x2 integer) (us "unique sequence"))
                                     ("member has index in sequence" thing x1 us)
                                    ("member has index in sequence" thing x2 us))
                                  (= x1 x2)))
    OCL Constraint:
                              context _'unique sequence'
                                  ???
regular sequence
    Definition:
                              consecutive sequence that is a unique sequence
```

CLIF Definition: (forall (s)

(iff ("regular sequence" s)

(and ("consecutive sequence" s)

("unique sequence" s))))

Regular sequences are the basis of scales (clause D.3). Note:

finite sequence

Definition: sequence that has a cardinality

indefinite sequence

Definition: sequence that does not have a cardinality

Note: This definition relies on the fact that 'set has cardinality' (in MRV) has the Necessity

"Each set has at most one cardinality." An indefinite sequence has an unknown or

unspecified number of <u>elements</u>, hence it does not have a '<u>cardinality</u>'.
'<u>Finite sequence</u>' is used in this specification as the basis '<u>finite time scales</u>', such as the Note:

'Gregorian year of months scale'. 'Indefinite time sequence' is the basis of

'indefinite time scales' such as the 'Gregorian years scale'. The key distinction is that finite time scales have a specified number of sequence positions, whereas the number of

sequence positions of indefinite time scales is not known.

Different scientific, religious, and cultural traditions have varying views as to whether there Note:

is a first or last <u>calendar year</u>. This specification avoids taking a position about that by

using the term 'indefinite sequence' rather than 'infinite sequence'.

Sequence Member Relationships D.2.5

The following concepts are relationships that a sequence imposes on its members.

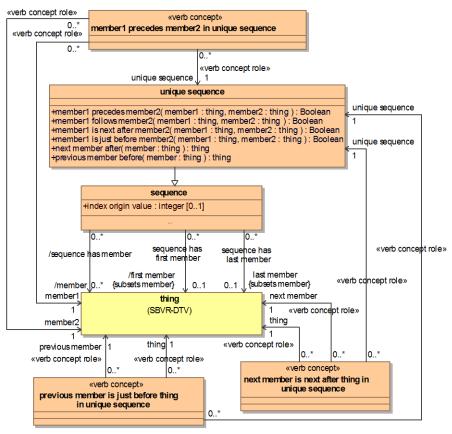

Figure D.4 - Sequence Member Relationships

member₁ precedes member₂ in unique sequence

Synonymous Form: Definition:

member₂ follows member₁ in unique sequence member₁ participates in the unique sequence

and member₂ participates in the unique sequence

and each sequence position of member in the unique sequence precedes each

<u>sequence position₂ of member₂ in the unique sequence</u>

```
CLIF Definition:
                              (forall ((s sequence)(m1 thing)(m2 thing))
                              (iff ("member1 precedes member2 in unique sequence"
                                  m1 m2 s)
                                  (and
                                   ("member participates in sequence" m1 s)
                                   ("member participates in sequence" m2 s)
                                   (forall ((sp1 "sequence position")
                                        (sp2 "sequence position"))
                                    (if

D.3 Quantities Vocabulary (informative)

Quantities model many of the concepts in the International Vocabulary for Measures [VIM].

Deleted: 20150301

Quantities Vocabulary

General Concept: terminological dictionary Included Vocabulary: SBVR-DTV Vocabulary

Language: **English**

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#QuantitiesVocabulary

D.3.1 Quantities

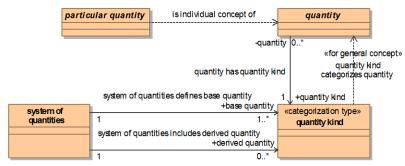

Figure D.7 - Quantities

quantity

Definition: property of a phenomenon, body, or substance, to which a number can be assigned with

respect to a reference

VIM 1.1 'quantity' Dictionary Basis:

The term 'quantity' is used here to refer to the abstraction of the properties – the amount of Note:

measurable "stuff" that can be compared between particular quantities. The "height of the Washington Monument" refers to a 'particular quantity; "555 ft 5 inches" refers to a

'quantity value'

Note: This is not the SBVR concept 'quantity,' which is deprecated and not used in this model. Example: second, kilogram, joule, meter. These are quantities in a general sense, which is what is

meant here by 'quantity.

Note: A quantity as defined here is said to be a "scalar" as distinct from a "vector." However, a

vector or a tensor whose components are quantities is also considered to be a quantity.

particular quantity

a property that is of an individual thing and is quantifiable as an instance of some quantity Definition:

<u>kind</u>

The weight of a given person, the mass of the Earth, the speed of light, and the distance between New York and Paris are said to be "particular quantities." Note:

A particular quantity is given by a definite description, which identifies the individual Note:

thing and the property. Particular quantities are properties of particular things and are

generally expressed by a term for the property and a quantity value.

Note: Particular quantities appear in fact models as individual concepts that refer to

instances of 'quantity.' Thus, a conceptual schema might have the fact type "meeting

lasts duration," where "duration" is a specialization of "quantity." (See the note about "duration" under "quantity kind.") A fact model might include the fact "last Monday's meeting lasted 2hr 20min." The definite description "the duration of last Monday's meeting" defines a particular quantity, an individual concept whose one instance is the quantity (thing) that is quantified by the quantity value "2 hr 20 min." "2hr 20 min." is a compound quantity value of quantity kind "duration.

Reference Scheme: A definite description of the particular quantity.

quantity kind

Definition: categorization type for 'quantity' that characterizes quantities as being mutually

comparable

Concept Type: categorization type Dictionary Basis: VIM 1.2 'kind of quantity' Example: duration, mass, energy, length

Note: Every instance of 'quantity kind' is also a specialization of 'quantity'. So the concept 'duration' is an instance of 'quantity kind' and it is a specialization of 'quantity', i.e., it

is a classifier of actual quantities. But a given duration (i.e., the duration of something) is an instance of 'duration' and thus a 'particular quantity,' not an instance of 'quantity kind'. For example, a 'year' is not an instance of quantity kind; it is an instance of

quantity, but not a category of quantity.

Note: The quantities "year" and "second" are instances of quantity, and they are both instances

of the quantity kind 'duration' and are mutually comparable. Quantities of time given in years and seconds are comparable, although some transformation of quantity values (see below) is needed to compare them. Similarly 'metre' is an instance of 'length,' and 'foot' is another instance of 'length' that is comparable to 'metre,' although conversions are required when comparing values. But 'metre' is not comparable to 'second', because 'length' and 'duration' are disjoint quantity kinds. Only quantities of the same kind are mutually

comparable.

All <u>duration quantities</u> are comparable regardless of the role they play - the particular Note:

properties they instantiate. The <u>duration</u> of the warranty on an automobile can be compared with the expected life of the battery, even though those are very different particular quantities. Similarly, the height of a tower can be compared to the distance one can see from the top, because they are both length quantities, even though they are unrelated

properties.

Note: The concept 'height' is a role of quantities of the quantity kind 'length'. In principle,

> 'height' could be considered a <u>category</u> of 'quantity' (a sub-category of 'length') and therefore its own 'quantity kind.' The concept 'range of a weapon' is a different role of length quantities. If we want to treat the height of a target as comparable to the range of a weapon, it is inadvisable to treat height and range as different quantity kinds. This idea is

the basis for the 'system of quantities' concept.

quantity has quantity kind

Definition: quantity is an instance of the category of quantity that is the quantity kind

Necessity: Each quantity has exactly one quantity kind.

CLIF Axiom: (forall ((q quantity))

(exists ((qk "quantity kind"))

(and

("quantity has quantity kind" q qk)

(forall (qk2)

(if

("quantity has quantity kind" q qk2)

(= qk2 qk))))))

OCL Constraint: context quantity

inv: 'quantity kind'->allInstances(one qk | self. 'quantity kind' = qk)

Example: hour (the duration) is an instance of 'duration' - a specific quantity of time. So the

quantity kind of 'hour' is 'duration'.

system of quantities

Definition: set of quantities together with a set of non-contradictory equations relating those

Dictionary Basis: VIM 1.3 'system of quantities'

system of quantities defines base quantity

base quantity

Definition: quantity kind in a conventionally chosen subset of a given system of quantities, where no

subset quantity can be expressed in terms of the others

Concept Type: <u>role</u>

Dictionary Basis: VIM 1.4 'base quantity'

The International System of Quantities (ISQ) comprises these base quantities (with their Example:

SI base measurement units): length (meter)

mass (kilogram) duration (second) electric current (ampere)

thermodynamic temperature (kelvin)

amount of substance (mole) luminous intensity (candela)

These base quantities are not mutually comparable. All quantities of any one of

these kinds are, however, mutually comparable. See also "quantity kind."

system of quantities includes derived quantity

derived quantity

Definition: quantity kind, in a system of quantities, that is not a base quantity of the system but

may be defined in terms of base quantities of the system

Dictionary Basis: VIM 1.5 'derived quantity'

Example: velocity (length/time), mass density (mass/length3) Commented [EB143]: Issue 13-65 INSERT text

D.3.2 Measurement Units

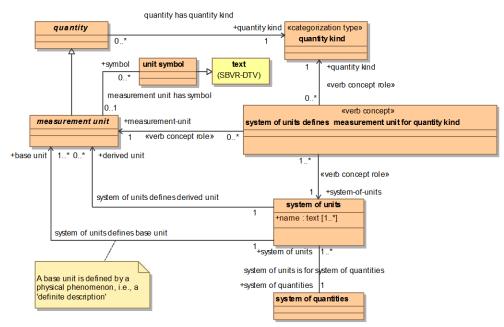

Figure D.8 - Measurement Units

measurement unit

Definition: quantity, defined and adopted by convention, with which any other quantity of the same

kind can be compared to express the ratio of the two quantities as a number

Dictionary Basis: VIM 1.9 'measurement unit'

Example: <u>week, day, hour, minute, second,</u> kilogram, joule, meter

system of units

Definition: a set of measurement units associated with a system of quantities, together with a set of

rules that assign one <u>measurement unit</u> to be the <u>base unit</u> for each <u>base quantity</u> in the <u>system of quantities</u> and a set of rules for the derivation of other units from the <u>base</u>

units

Example: The International System of Units (SI) is a system of units.

system of units is for system of quantities

Necessity: Each system of units is for exactly one system of quantities.

CLIF Axiom: (forall ((sou "system of units"))

(exists ((soq "system of quantities"))

(and

("system of units is for system of quantities" sou soq)

(forall (soq2)

(if ("system of units is for system of quantities" sou soq2)

(= soq2 soq)))

)))

OCL Constraint: context _'system of units'

self._'system of quantities'->size() = 1

system of units defines measurement unit for quantity kind

Synonymous Form: measurement unit is defined for quantity kind by system of units

Definition: The system of units identifies the measurement unit as the reference measurement unit

for the quantity kind.

Note: A <u>system of units</u> defines one <u>base unit</u> for each <u>base quantity</u> in the <u>system of</u>

<u>quantities</u> that it is for. It may define additional <u>measurement units</u> (<u>derived units</u>) for the same <u>quantity kinds</u>. It may define <u>derived units</u> for <u>derived quantities</u>, or it may

define a mechanism for expressing derived units.

system of units defines base unit

base unit

Definition: measurement unit that is defined for a base quantity by a system of units

Concept Type: role

Dictionary Basis: VIM 1.10 'base unit'

Note: Quantity units that are not <u>base units</u> are <u>derived units</u>.

Example: See the example SI units under "<u>base quantity</u>".

system of units defines derived unit

derived unit

Definition: measurement unit for a derived quantity

Dictionary Basis: VIM 1.11 'derived unit'

Note: Every <u>derived unit</u> is defined in terms of <u>base units</u>

Example: $\frac{1}{\text{Example}}$ $\frac{\text{minute}}{1 \text{ stere}} = \frac{60}{1 \text{ stere}}$ $\frac{\text{seconds}}{1 \text{ stere}}$ Example: $\frac{1}{1 \text{ inch}} = 0.0254 \text{ metre}$

International System of Units

Synonym: S

Definition: The system of units that is defined for the International System of Quantities by the

International Standard ISO 80000.

Source: VIM 1.16.

D.3.3 Quantity values

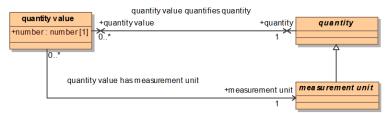

Figure D.9 - Class Diagram for Quantity Values

quantity value

Example:

Definition: <u>number and measurement unit together giving magnitude of a quantity</u>

Dictionary Basis: VIM 1.19 'quantity value'

Note: The <u>quantity</u> expressed by a <u>quantity value</u> is the <u>quantity</u> whose ratio to the

measurement unit is the number. 2 days, 3.5 hours, 150 lb, 45.5 miles

quantity value quantifies quantity

Synonymous Form: <u>quantity</u> is quantified as <u>quantity</u> value

Synonymous Form: <u>quantity value of quantity</u>

Synonymous Form: <u>quantity value</u> expresses <u>quantity</u>

Definition: The quantity value gives the magnitude of the quantity.

Possibility: More than one quantity value may quantify a particular quantity.

Example: The <u>duration</u> of a meeting is a <u>particular quantity</u> that might <u>be quantified</u> as "<u>1</u> <u>hour</u>" or

as "<u>6</u> <u>minutes</u>".

D.4 Mereology (normative)

Mereology is the study [Simons] [Casati] of the relationships among whole things and their parts. This specification relies upon the following mereology axioms, among others, to define the properties of time intervals.

Mereology Vocabulary

General Concept: terminological dictionary
Included Vocabulary: SBVR-DTV Vocabulary

Language: English

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#MereologyVocabulary

Deleted: 20150301

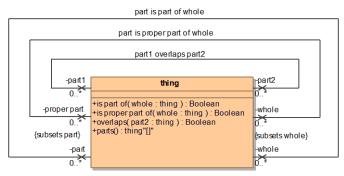

Figure D.10 - Mereology

whole

Concept Type: role
General Concept: thing

part

Concept Type: role
General Concept: thing

part is part of whole

Synonymous Form: whole includes part

Definition: The <u>part</u> is a component of the <u>whole</u>.

Note: There are a number of axioms of mereology that apply to the concept 'part is part of

whole.' The following 3 axioms specify only that subset of those axioms that are needed by this specification. This subset is needed to define the partial ordering relationship among

time intervals.

Note: Axiom of *reflexivity*: every <u>part</u> is <u>part</u> of itself.

Necessity: Each part is part of the part.

CLIF Axiom: (forall (part)

("part of" part part))

OCL Constraint: context thing

inv: self.part->exists(self)

Note: Axiom of antisymmetry: two distinct parts cannot be part of each other.

Necessity: If the part is part of the whole and the whole is part of the part then the part is the

whole.

CLIF Axiom: (forall ((part thing) (whole thing))

OCL Constraint: context thing

inv: self.whole->exists(p |

p.whole ->exists(self))
implies self = self.whole

Note: Axiom of transitivity

Necessity: If the part is part of some whole and the whole is part of some part3 then the part is

part of part3.

```
CLIF Axiom: (forall ((part thing) (whole thing) (part3 thing))
(if (and ("part of" part whole)
```

("part of" whole part3))
("part of" part part3)))

OCL Constraint: context thing

inv: self.whole->exists(whole |
 whole.whole->exists(part3 |
 part3 implies self._'part of(part3)))

The combination of the reflexivity, anti symmetry, and transitivity axioms define a partial ordering among things that have the 'part is part of whole' relationship.

thing overlaps thing

```
there exists a thing that is part of thing, and that is part of thing,
Definition:
CLIF Definition:
                            (forall (thing1 thing2)
                            (iff (overlaps thing1 thing2)
                                (exists (thing3)
                                 (and
                                   ("part of" thing3 thing1)
                                   ("part of' thing3 thing2)))))
OCL Definition:
                            context thing
                             def: self.overlaps(thing2: thing): Boolean =
                                self.part->exists(thing3 | thing2.part->exists(thing3))
                            Two things overlap if they have some part in common.
Note:
                            It is obvious from the definition that 'thing1 overlaps thing2' is symmetric.
Note:

DTV v1.3 Change-barred version	dtc/2016-02-21

Annex E - Formalizing English Tense and Aspect

(informative)

E.1 General

The normative clauses of this specification deal the semantics of time as used natural languages. This Annex describes how propositions that are given in English language syntax may be formulated using the Date-Time Vocabulary.

E.2 Syntax and Semantics of Time

Many natural languages have built-in syntactical mechanisms for expressing when an action occurs relative to the time of utterance or writing, or relative to the occurrence of another event. They also have standard ways of indicating whether and when an action is progressing or is accomplished. These mechanisms include the use of affixes with verbs, called *tense*, and the use of auxiliary verbs together with the main verb of a clause, called *aspect*. Not all languages have the same set of these kinds of mechanisms.

The terms 'tense' and 'modal' are used with somewhat different connotations when referring to syntax or semantics. In syntactic theory, 'tense' refers to different verb forms used to denote different times: past, present, or future. The term 'tense' can also be used to refer to the semantics of a temporal expression: the past tense, the present tense, the future tense. All languages incorporate mechanisms to express such semantics, but different languages have different syntactical mechanisms for doing so. Confusion sometimes arises in English, which has verb forms only for present tense and past tense. Consequently, it is common for some authors to say that English has only two tenses, past and present, and no future tense. At the same time, it is often said that the future tense in English is expressed using the auxiliary verb 'will'. In this annex, 'tense' refers to verb forms that express past or present time, and 'aspect' to the use of auxiliaries to generate different senses of past, present, and future time. In the normative clauses of the specification, 'tense' refers to the semantics of past, present, or future time, without regard to the syntactical mechanisms employed to express time in any language.

The term 'modal' can be confused with 'modality.' In this annex, 'modal' is a grammatical term that refers to a modal verb (see 'modal' below). 'Modality' is a logical term, used in SBVR, to refer to the mood of a proposition as involving the affirmation of either possibility, impossibility, necessity, contingency, obligation, or permission. SBVR includes a modal logic for these modalities, including modal formulae and modal negation rules. This specification does not provide a temporal logic for the temporal modality, rather temporal concepts are handled by the introduction of first order concepts and fact types defined in the normative clauses of this specification. No temporal logical operations are introduced in this specification. Negation of propositions involving time is treated conventionally as logical negation as specified in SBVR.

English syntax involving modal auxiliary verbs serves to denote both the tense and the logical mood of a proposition. The meaning depends on the particular auxiliary verbs used. A temporal connotation can be associated with each auxiliary verb, such that auxiliary verbs carry both a temporal connotation and a mood. The following table gives some examples.

Table E.1 - Modalities for Auxiliary Verbs

Auxiliary Verb	Time Frame	Modality	
can	present	possibility	
can not	present	impossibility	
could	past	possibility	
do not	future	negation	

does not	present	negation
did not	past	negation
may	present	permission
might	past*, future	possibility
must	past*, future	obligation
need	always	necessity
shall	future	necessity
should	past*, future	contingency
used	past	
will	future	
would	past	
	* with have	

Logical negation can be indicated by using *not* with an auxiliary verb; only a few examples are shown. *Always, never*, or *not ever* can be used with some modal auxiliary verbs to indicate *at all times*, or *not at any time*, as the case may be. Some words that serve as auxiliary verbs can have other grammatical roles as well. Time frame and modality can be expressed by means other than auxiliary verbs; this annex focuses on the behavior of English verbs in referring to time.

E.3 Organization of This Annex

This specification includes fact types that accurately capture the meaning of relationships between states of affairs and time, but the fact type forms needed for precise definition are not idiomatic. This annex describes a way to accommodate idiomatic English expressions involving time, giving rules for mapping such expressions to concepts provided in this specification preparatory to creating closed logical formulations of the idiomatic expression. This treatment is informative, not normative; other approaches are possible. It is extensive but not exhaustive; the most common cases are treated, but not all possibilities. A formal grammar of the tense and aspect in English is provided, followed by a general algorithm for performing the syntax-to-semantics transformations for the twelve grammatical categories. Finally, a table of specific cases of the use of tense and aspect in English is provided.

This annex only describes formulations in which time is denoted by verbs. Other temporal constructs, such as the use of literal duration values and time coordinates and expressions involving relationships between time periods, are not discussed here.

This annex effectively extends the modal operations described in SBVR Annex F The RuleSpeak® Business Rule Notation, to include time, but stops short of being a full treatment of temporal modality.

E.4 Definitions

The following definitions are excerpted from Sag, Wasow, and Bender, Syntactic Theory, Second Edition, Stanford University, Center for the Study of Language and Information (2003), Glossary.

tense Finite verbs come in different form depending on the time they denote; these forms are called 'tenses'. English has present and past tense, exemplified by the present tense forms *walk* and *walks*, and by the past tense form *walked*. Some languages also have future tenses, but English uses other means (e.g., the modal [q.v.] *will*) to express future time.

aspect Many language have special grammatical elements for locating in time the situation referred to. Among the temporal notions often expressed are whether situations are in process or completed and whether they occur repeatedly. These notions are often called 'aspect,' and words or affixes whose function is to express aspect are called 'aspectual markers.' *See also* perfective, progressive.

finite verb A finite verb is one that is marked for tense [q.v.] (present or past, in English).

modal The English verbs *can*, *could*, *may*, *might*, *must*, *shall*, *should*, *will*, and *would*, along with their negated forms (*can't*, etc.) are referred to as 'modals' or 'modal verbs.' They share the following properties: they function only as finite verbs [q.v.]; they exhibit auxiliary behavior (negation, inversion, contraction, and ellipsis); they take base VP [verb phrase] compliments; and they show no agreement [q.v.] (i.e., no third-person singular –*s* suffix). Some other languages have similar syntactically distinctive classes of words expressing necessity, possibility, obligation, and permission; these are also known as modals.

agreement In many languages, the form of certain elements can vary to indicate such properties such as person [referring to the speaker, the hearer, or third parties], number [referring to single entities or multiple entities], gender, etc. Often, these variations are marked with affixes. Some grammatical relationships between pairs of linguistic elements require they agree on these properties. In English, for example, present tense verbs are marked to indicate whether the subjects are third-person singular (with the suffix -s), and nouns indicate plurality (also with a suffix -s). The systematic covariation of the forms of the subject and verb is called 'subject-verb agreement'. Similarly, pronouns must agree with their antecedents in person, number, and (if third-person) gender.

perfective Many languages have special verb forms or constructions used to indicate that the event denoted by the verb is completed. These are referred to as 'perfective' (or just 'perfect') in aspect. The English perfective involves the combination of *have* with a past participle [q.v.], as in *The dog has eaten the cake. See also* aspect.

progressive Special verb forms or construction used to indicate that the event denoted by the verb is in progress are referred to as 'progressive' aspect. The English progressive involves combination of *be* with a present participle [q.v.], as in *The dog is eating the cake. See also* aspect.

participle Certain nonfinite verbs – usually ones that share some properties with adjectives – are referred to as 'participles.' English has three types of participles: present participles, which end in –ing and usually follow some form of be; past participles, which usually end in –ed or –en and follow some form of have; and passive participles, which look exactly like past participles but indicate the passive voice [q.v.]. The three participles of eat are illustrated in the following sentences:

- (i) Termites are eating the house.
- (ii) Termites have eaten the house.
- (iii) The house was eaten by termites.

E.5 English Grammar of Tense and Aspect

English grammar for tense and aspect can be defined as follows, using Extended Backus Nauer Form notation (ISO/IEC 14977 Information technology – Syntactic metalanguage - Extended BNF). '::=" means 'is defined as.' Each '::=' statement is a production rule. Each production rule is terminated by ';'. The order of the symbols on the right hand side of each production rule is significant, unless delimited by '|'. '|' means 'or', a choice. Brackets '[]' indicate the element is optional. Quoted words are literals. Comments are included between '(* and '*)'.

```
S ::= NP AUX VP; (* S-sentence, NP-noun phrase, VP-verb phrase *)

AUX ::= [MODAL] [PERF] [PROG]; (* auxiliary verb *)

MODAL ::= 'can' | 'could' | 'may' | 'might' | 'must' | 'shall' | 'should' | 'used' | 'will' | 'would';

PERF ::= 'have' | 'has' | 'had'; (* perfective *)

PROG ::= 'is' | 'are' | 'was' | 'were' | 'be' | 'been'; (* progressive *)
```

Additional Rules for Auxiliaries (AUX)

- 1. Auxiliaries are optional.
- 2. Auxiliaries precede any non-auxiliary verb.
- 3. Auxiliaries determine the form of the following verb.
- 4. Auxiliaries can co-occur with each other, but only in a fixed order.
- 5. Auxiliaries of any given type cannot iterate.

The modals all indicate future time. They have the additional property of expressing necessity, possibility, obligation, or permission, as discussed in SBVR.

Not all combinations generated by the above grammar are valid English. Other rules apply, not given, such as subject-verb agreement. *Not, never, always,* or *not ever* can be used with some modals; these grammatical details are outside the scope of this annex, but the methods of this annex can be extended to include them. The table in E.6 gives a listing of grammatical constructs that appear regularly in English.

Reference: Sag, Wasow, and Bender (ibid.), pp.392-394.

E.6 Formulating Tense and Aspect

The general approach used here to formulate a sentence involving tense or aspect is as follows:

- Transform the sentence into a proposition based on the applicable fact type form in the conceptual schema, noting
 the original tense and aspect.
- 2. Identify the situation kind that the base proposition describes.
- Restrict the <u>situation kind</u> by instantiating one or more of the fact types defined in this specification involving states of affairs and time, as noted in 1.
- 4. Create closed logical formulations that mean the base proposition and its restrictions, as described in SBVR.

Transform to a base proposition

All propositions in SBVR are considered to be true or false when considered with respect to a given fact model. A proposition might be true when considered with respect to one fact model, and false when considered with respect to another. Each fact model is taken to be a snapshot of the state of the universe of discourse at some time. The fact model is tantamount to a database, and the veracity of each proposition is based on the facts in the database at the time of the snapshot, which time may or may not be stated. This is standard SBVR.

Propositions in standard SBVR are expressed preferably in the simple present tense when finite verbs are used. Such propositions are considered untensed, as they apply to any fact model representing the state of the universe at the snapshot time of the fact model. Propositions involving non-finite verbs are also considered untensed in standard SBVR.

This specification includes the concept <u>now</u>, which is the current time, or present. When evaluating propositions using this specification, now is the snapshot time of the fact model with respect to which the propositions are being evaluated.

Transforming a proposition into an base form involves changing the verb to the tense of the applicable fact type in the conceptual schema, maintaining subject-verb agreement.

For example, the present perfect progressive sentence "Acme has been trading with Xycore" transforms to untensed "Acme trades with Xycore," with the notation that the original is present perfect progressive. These sentences are both based on the fact type company₁ trades with <a href="mailto:company₂.

Commented [EB145]: Issue 13-4 DELETE text

Deleted: This sub clause needs to be updated to reflect the term "situation kind" as used in this specification, instead of "state of affairs."

Commented [EB147]: Issue 13-4 REPLACE text

Deleted: Identify the state of affairs that corresponds to the base proposition.

Commented [EB148]: Issue 13-4 REPLACE all instances of term

Deleted: state of affairs

The guidance is generally not to encode tense or aspect into fact type forms unless the domain model specifically requires a particular tense or aspect for that fact type. Consider this example, "Six tasks have completed on May 5, 2010" may be based on the fact type "task completed on time point." This fact type has an intransitive past tense verb. The conceptual schema has already restricted facts of this type to past or perfected. The example transforms to "Six tasks completed on May 5, 2010" with a notation that the original is present perfect. A different conceptual schema might include the fact type "task completes on time point" instead. The proposition then transforms to "Six tasks complete on May 5, 2010" with the same present perfect notation. The "completes on" fact type, unlike the "completed on" version, could be used for facts about future planned completions (will complete on). This illustrates that there is a certain economy in using simple-present fact type forms in domain models: every different tense and aspect variation of these sentences is based on the same fact type and transforms to the same untensed form.

Identify the situation kind

The situation kind of interest is the one that is described by the transformed sentence, the base proposition

Restrict the situation kind

The <u>situation kind</u> is restricted by involving it in a role in an instance of appropriate fact type(s) from this specification. Which fact types to use depends on the tense and aspect of the original sentence, as noted at the time the base proposition was created. Create a fact instance of each of the appropriate fact types.

Create closed logical formulations

A closed logical formulation is created for the conjunction of the base proposition and the restricting facts. This constitutes the closed logical formulation of the original sentence.

E.7 Mapping Tense and Aspect to the Date-Time Vocabulary

This table is extensive but not exhaustive. Different modals can be substituted for 'will,' with other restrictions in the logical formulation (e.g., obligatory). In some of the examples, the 'now' time is apparently in the past, to accord with the history of James Joyce.

Deleted: state of affairs

Commented [EB149]: Issue 13-4 REPLACE text

Deleted: The state of affairs of interest is the one that corresponds to the transformed sentence, the base form. This is an instance of the SBVR fact ty pe meaning corresponds to thing, where the meaning is the base proposition and the thing is a state of affairs

Deleted: state of affairs

Deleted: state of affairs

Table E.2 - Mapping Tense and Aspect to the Date-Time Vocabulary

MODAL	PERF sg/pl	PROG sg/pl	Verb Form	Grammatical Term	Example: person writes book	Date-Time Vocabulary Fact Type
			present	present simple	Joy ce writes Uly sses.	None. This is the base situation kind (s) s: "Joy ce writes Ulysses"
			past	past simple	Joy ce wrote Uly sses.	s is in the past
used			infinitive	past simple	Joy ce used to write Uly sses.	s is in the past
will			present	future simple	Joy ce will not write Uly sses.	s is in the future and s is not an actuality
		is/are	present participle	present progressive	Joy ce is writing Uly sses in 1919.	s holds within 1919
		was/were	present participle	past progressive, imperfective	Joy ce was writing Uly sses in 1919.	s is in the past and s holds within 1919
will		be	present participle	future progressive	Joy ce will not be writing Uly sses in 2012.	s is in the future and s does not hold within 2012
	has/have		past participle	present perfective	Joy ce has written Uly sses.	s is accomplished
	had/had		past participle	past perfective, pluperfect	Joy ce had written Uly sses by 1922.	s is in the past and s is accomplished and s occurs before 1922
will	have		past participle	future perfective	Joy ce will have written Uly sses by 1922.	s is in the future and s is accomplished and s occurs before 1922
	has/have	been	present participle	present perfect progressive	Joy ce has been writing Uly sses in 1919.	s holds within 1919 and s is accomplished
	had	been	present participle	pluperfect progressive	Joy ce had been writing Uly sses in 1919.	s is in the past and s holds within 1919 and s is accomplished
will	have	been	present participle	future perfect progressive	By the end of 1920, Joy ce will have been writing Uly sses for 33 months.	s is in the future and s holds during December 1920 – 33 months

Commented [EB150]: Issue 13-4 REPLACE term

Deleted: state of affairs

Annex F - Vocabulary Registration Vocabulary

(normative)

F.1 Vocabularies Presented in this Document

This annex formally lists the vocabularies provided by the Date-Time Vocabulary specification.

Date-Time Vocabulary Registration Vocabulary

General Concept: terminological dictionary

Language: English

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#DTVRegistrationVocabulary

Date-Time Vocabulary Registration Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Note: This vocabulary formally registers all the vocabularies specified in this document.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#DTVRegistrationVocabulary

Time Infrastructure Vocabulary

General Concept: terminological dictionary

Language: English

Description: The primary purpose of this vocabulary is to enable the definition of various kinds of

calendars, such as fiscal, lunar, or religious calendars. Most end users will use one of the calendars defined in this document and should not need many of the concepts defined here.

Note: See Clause 8.

Namespace URI: http://www.omg.org/spec/DTV_20160301/dtv-sbvr.xml#TimeInfrastructureVocabulary

Duration Values Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Description: <u>Duration values</u> are amounts of time stated in terms of one or more <u>time units</u>.

Note: See Clause 9.

Field Code Changed

Gregorian Calendar Vocabulary

General Concept: terminological dictionary

Language: English

Description: The Gregorian Calendar is the standard calendar, used worldwide.

Note: See Clause 11.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-

sbvr.xml#GregorianCalendarVocabulary

ISO Week Calendar Vocabulary

General Concept: <u>terminological dictionary</u>

Language: English

Description: Defines the standard calendar based on 7-day weeks.

Note: See Clause 12.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#WeekCalendarVocabulary

Time of Day Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Description: Defines the time scales, time points, and time coordinates that comprise the <u>calendar day</u>.

Note: See Clause 13.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#TimeOfDayVocabulary

Internet Time Vocabulary

General Concept: <u>terminological dictionary</u>

Language: English

Description: Internet Time is the calendar of the Network Time Protocol (NTP), published by the Internet

Engineering Task Force (IETF).

Note: See Clause 14.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#InternetTimeVocabulary

Indexical Time Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Description: Indexical terms for time periods that are in common business use.

Note: See Clause 15.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#IndexicalTimeVocabulary

Situations Vocabulary

General Concept: terminological dictionary

Language: <u>English</u>

Description: A vocabulary that relates situations to time intervals and durations.

Note: See Clause 16.

Namespace URI: http://www.omg.org/spec/DTV_20160301/dtv-sbvr.xml#SituationsVocabulary

Schedules Vocabulary

General Concept: terminological dictionary

Language: <u>English</u>

Description: Schedules relate repeating situations to time.

270

dtc/2016-02-21

Note: See Clause 17.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#SchedulesVocabulary

Deleted: 20150301

Sequences Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Description: Model of ordered collections of things in which the things are ordered by assigning numbers

(indices) to them within the collection, as distinct from any particular properties of the

things themselves.

Note: See Annex D.2.

Namespace URI: http://www.omg.org/spec/DTV/20160301/dtv-sbvr.xml#SequencesVocabulary

Deleted: 20150301

Quantities Vocabulary

General Concept: <u>terminological dictionary</u>

Language: <u>English</u>

Description: A minimal set of the concepts defined in VIM.

Note: See Annex D.3.

Annex G - UML Profile for the SBVR Elements used in the Date-Time Vocabulary

(normative)

G.1 General

This annex specifies the stereotypes that are used to mark up UML model elements in the DTV specification.

A general UML Profile for SBVR concepts has not been developed by the OMG. It is expected that such a profile will be developed in the future. At such time, this Annex and the corresponding UML stereotypes in the DTV UML model will be superseded.

The UML metaclass Class is depicted in the diagram because it plays roles in stereotyped relationships. The UML metaclasses Association and Dependency are not depicted. They serve only as the UML base elements for some of the defined stereotypes.

G.2 Concept types

The SBVR term <u>concept type</u> refers to a concept whose instances are concepts. Two stereotypes are introduced to support this notion.

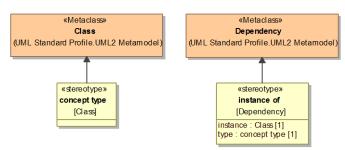

Figure G.1 - Concept types

G.2.1 Stereotype «concept type»

The stereotype «concept type» characterizes a UML Class as an SBVR concepttype. In UML terms, it is a classifier whose instances are classes.

G.2.2 Stereotype «instance of»

The stereotype <code>*instance of*</code> characterizes a UML Dependency as representing the relationship between a UML Class (representing an SBVR <code>concept</code>) and a <code>concept type</code> that <code>corresponds to</code> it. That is, the Dependency can be read "Class X is an instance of concept type Y."

The relationship of the <code>winstance</code> of <code>></code> Dependency to the (client) Class that is the instance is represented in the <code>winstance</code> of <code>></code> element by the Tag "instance".

The relationship of the <code>winstance</code> of <code>></code> Dependency to the (supplier) Class that is the concept type is represented in the <code>winstance</code> of <code>></code> element with the Tag "type".

G.3 Categorization

The SBVR term <u>categorization type</u> refers to a <u>concept type</u> whose instances are subtypes of a common base concept. A <u>categorization scheme</u> for the common base concept is a specific set of subtypes that are mutually exclusive. Three stereotypes are introduced to support this notion.

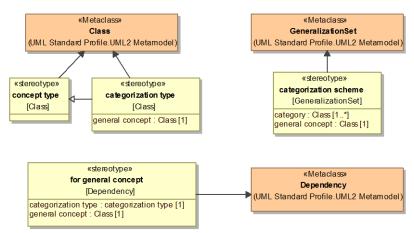

Figure G.2 - Categorization

G.3.1 Stereotype «categorization type»

The stereotype «categorization type» characterizes a UML Class as an SBVR categorization type.

A categorization type is similar to a UML Powertype. The instances of a Powertype are *all* the subclasses of a given Class. The instances of a <u>categorization type</u> are *all* the <u>categories</u> (specializations) of a given <u>general concept</u>, which is represented in UML by a Class.

The relationship of the <u>categorization type</u> to the Class that is the general concept that the categorization type is for is represented in the <u>«categorization type</u>» element by the Tag "general concept".

By comparison, the extension of categorization type is a particular set of subclasses of a given Class that are mutually exclusive. Only in some cases is the extension of a UML Powertype a set of subclasses that are mutually exclusive, partly because the Powertype necessarily includes all of the subclasses of the categorized Class.

Each categorization type has a «for general concept» Dependency on a 'base class' that is the "common base concept" of the instances.

G.3.2 Stereotype «for general concept»

The stereotype «for general concept» characterizes a UML Dependency as representing the relationship between a $\underline{\text{categorization type}}$ and the $\underline{\text{general concept}}$ that it categorizes. The Dependency is the diagram element that shows the relationship. The Dependency can be read "Categorization type X is for general concept Y."

The relationship of the «for general concept» Dependency to the (client) categorization type is represented in the «for general concept» element by the Tag "categorization type".

The relationship of the «for general concept» Dependency to the (supplier) Class that is the general concept is represented in the «for general concept» element with the Tag "general concept".

G.3.3 Stereotype «categorization scheme»

The SBVR term <u>categorization scheme</u> refers to a specific set of categories of a common general concept that are mutually exclusive. The stereotype «categorization scheme» characterizes a UML GeneralizationSet as a categorization scheme.

The relationship of the <u>categorization scheme</u> to the Class that is the general concept that the categorization scheme *is for* is represented in the «categorization scheme» element by the Tag "general concept".

The relationship of the <u>categorization scheme</u> to the Classes that are the mutually exclusive categories that the categorization scheme <u>includes</u> is represented in the «categorization scheme» element by the Tag "category".

G.4 Verb Concepts

The SBVR term <u>verb concept</u> refers to a concept whose instances are states, activities or events. A verb concept is said to have <u>verb concept roles</u> that characterize the participation of individual objects in those states, activities or events.

<u>Verb concepts</u> that involve only one or two participant objects can be represented in UML using Attributes and binary Associations. In a binary Association, the multiplicity on an Association End represents the number of instances of the verb concept that each instance of the other role can participate in, i.e., the number of times an instance of that class can play that role.

In theory, a verb concept involving more than two roles can be represented in UML by an N-ary Association. Support for N-ary associations in UML v2.4 tools is highly variable. For this reason, this specification represents a verb concept with 3 or more participating verb concept roles as a Class with a \times verb concept \times stereotype. Three stereotypes are introduced to support this approach.

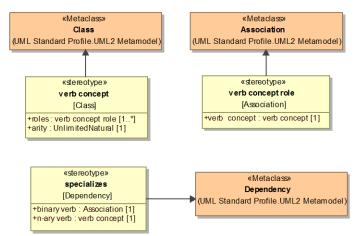

Figure G.3 - Verb Concept stereotypes

G.4.1 Stereotype «verb concept»

The stereotype «verb concept» characterizes a UML Class as an SBVR <u>verb concept</u>. In UML terms, it is a classifier whose instances are states.

Each «verb concept» Class has one «verb concept role» Association for each <u>verb concept role</u> in the SBVR <u>verb concept</u> that it represents.

The set of «verb concept role» Associations for the <u>verb concept</u> are represented in the «verb concept» element by the Tag "roles".

The number of verb concept roles for the verb concept is represented in the «verb concept» element by the Tag "arity".

G.4.2 Stereotype «verb concept role»

The stereotype «verb concept role» characterizes a UML Association as representing one <u>verb concept role</u> in an SBVR <u>verb concept</u> that is represented by a «verb concept» Class.

Each «verb concept role» Association represents exactly <u>one verb concept role</u> in exactly one SBVR <u>verb concept</u>.

Each link that instantiates that Association can be read: In the state (object) X that is the instance of the verb concept Class, the role Y is played by Z, where Y is the association end name on the Association, and Z is the object in the range Class.

One end of the «verb concept role» Association is the «verb concept» Class that represents the <u>verb concept</u>. The other end of the Association is the UML Class that represents the <u>range</u> of the <u>verb concept role</u>. The name of that association end is the <u>placeholder</u> for the <u>verb concept role</u> in the <u>verb concept form</u>.

In a «verb concept role» Association only the association end that refers to the range of the role is navigable, and it always has multiplicity one, because each <u>verb concept role</u> is played exactly once in any one instance of the <u>verb concept</u>.

The relationship of the <verb concept role» Association to the <verb concept» Class is represented in the <verb concept role» element by the Tag "verb concept".

G.4.3 Stereotype «specializes»

The stereotype «specializes» characterizes a UML Dependency as representing an instance of SBVR concept specializes concept, where the narrower concept is a binary verb concept that is represented by a UML Association, and the more general concept is a verb concept with more than two verb concept roles that is represented by a «verb concept» Class. That is, the Dependency can be read "binary verb concept X specializes verb concept Y."

The relationship of the «specializes» Dependency to the (client) binary verb concept is represented in the «specializes» element by the Tag "binary verb".

The relationship of the «specializes» Dependency to the (supplier) «verb concept» Class that is the more general verb concept is represented in the «specializes» element with the Tag "n-ary verb".

Note: A binary verb concept can specialize an n-ary verb concept by supplying in its definition a specific thing to play one of the verb concept roles in the n-ary verb concept. In practice, it also constrains the ranges of other verb concept roles in the n-ary verb concept.

time interval<sub>1</sub> is between time interval<sub>2</sub> and time interval<sub>3</sub> 42
time interval<sub>1</sub> is between time interval<sub>2</sub> to time interval<sub>3</sub> 42
time interval<sub>1</sub> is followed by time interval<sub>2</sub> 30
time interval<sub>1</sub> is in time interval<sub>2</sub> 28
time interval<sub>1</sub> is part of time interval<sub>2</sub> 28
time interval<sub>1</sub> is properly before time interval<sub>2</sub> 34
time interval<sub>1</sub> is properly during time interval<sub>2</sub> 36
time interval, is the duration following time interval, 69
time interval is the duration preceding time interval 68
time interval<sub>1</sub> is the intersection of time interval<sub>2</sub> with time interval<sub>3</sub> 51
time interval<sub>1</sub> is the same as time interval<sub>2</sub> 35
time interval<sub>1</sub> meets time interval<sub>2</sub> 35
time interval<sub>1</sub> overlaps time interval<sub>2</sub> 29
time interval<sub>1</sub> plus time interval<sub>2</sub> 44
time interval<sub>1</sub> plus time interval<sub>2</sub> is time interval<sub>3</sub> 43
time interval<sub>1</sub> precedes time interval<sub>2</sub> 30
time interval<sub>1</sub> properly overlaps time interval<sub>2</sub> 36
time interval starts before time interval 38
time interval<sub>1</sub> starts duration before time interval<sub>2</sub> 67
time interval<sub>1</sub> starts during time interval<sub>2</sub> 39
time interval<sub>1</sub> starts time interval<sub>2</sub> 37
time interval<sub>1</sub> starts time interval<sub>2</sub> complementing time interval<sub>3</sub> 47
time interval<sub>1</sub> starts when time interval<sub>2</sub> starts 39
time interval<sub>1</sub> starts with time interval<sub>2</sub> 39
time interval<sub>1</sub> starts within time interval<sub>2</sub> 39
time interval, through individual situation kind 226
time interval<sub>1</sub> through occurrence 223
time interval through occurrence specifies time interval 223
time interval<sub>1</sub> through time interval<sub>2</sub> 44
time interval<sub>1</sub> to individual situation kind 226
time interval<sub>1</sub> to occurrence 223
time interval<sub>1</sub> to occurrence specifies time interval<sub>2</sub> 223
time interval<sub>1</sub> to time interval<sub>2</sub> 46
time interval<sub>1</sub> to time interval<sub>2</sub> is time interval<sub>3</sub> 46
time interval<sub>1</sub> to time interval<sub>2</sub> specifies time interval<sub>3</sub> 46
time interval<sub>1</sub> until occurrence 223
time interval, until occurrence specifies time interval, 223
time interval, until individual situation kind 226
time interval<sub>1</sub> until individual situation kind specifies time interval<sub>2</sub> 226
time interval<sub>1</sub>through individual situation kind specifies time interval<sub>2</sub> 226
time interval<sub>1</sub> to individual situation kind specifies time interval<sub>2</sub> 226
time interval<sub>2</sub> > time interval<sub>1</sub> 30
time interval<sub>2</sub> ends before time interval<sub>1</sub> 41
time interval<sub>2</sub> follows time interval<sub>1</sub> 30
time interval<sub>2</sub> immediately follows time interval<sub>1</sub> 35
```

```
time interval<sub>2</sub> includes time interval<sub>1</sub> 28
time interval<sub>2</sub> is after time interval<sub>1</sub> 30
time interval<sub>2</sub> is duration after time interval<sub>1</sub> 66
time interval<sub>2</sub> is duration before time interval<sub>1</sub> 66
time interval<sub>2</sub> is finished by time interval<sub>1</sub> 37
time interval<sub>2</sub> is individual situation kind through time interval<sub>1</sub> 226
time interval<sub>2</sub> is individual situation kind to time interval<sub>1</sub> 227
time interval<sub>2</sub> is met by time interval<sub>1</sub> 35
time interval<sub>2</sub> is occurrence through time interval<sub>1</sub> 223
time interval<sub>2</sub> is preceded by time interval<sub>1</sub> 30
time interval<sub>2</sub> is properly after time interval<sub>1</sub> 34
time interval<sub>2</sub> is properly overlapped by time interval<sub>1</sub> 36
time interval<sub>2</sub> is started by time interval<sub>1</sub> 37
time interval<sub>2</sub> is time interval<sub>1</sub> through individual situation kind 226
time interval<sub>2</sub> is time interval<sub>1</sub> through occurrence 223
time interval<sub>2</sub> is time interval<sub>1</sub> to individual situation kind 226
time interval<sub>2</sub> is time interval<sub>1</sub> to occurrence 223
time interval<sub>2</sub> is time interval<sub>1</sub> until individual situation kind 226
time interval is time interval until occurrence 223
time interval<sub>2</sub> overlaps time interval<sub>1</sub> 29
time interval<sub>2</sub> properly includes time interval<sub>1</sub> 36
time interval<sub>2</sub> starts after time interval<sub>1</sub> 38
time interval<sub>2</sub> starts duration after time interval<sub>1</sub> 66
\underline{\text{time interval}_3} = \underline{\text{time interval}_1} + \underline{\text{time interval}_2} 43
time interval<sub>3</sub> from time interval<sub>1</sub> to time interval<sub>2</sub> 46
time interval<sub>3</sub> is time interval<sub>1</sub> plus time interval<sub>2</sub> 43
time of day 107
time of day coordinate 133
time of day coordinate of date time 134
time of day coordinate with time offset 118
Time of Day Vocabulary 177
Time of Day Vocabulary 300
time offset 116
\underline{\text{time offset}} = \underline{\text{calendar}_2} - \underline{\text{calendar}_1} \quad 117
time offset of calendar<sub>1</sub> from calendar<sub>2</sub> 117
time offset of local calendar 120
time period 80
time period ? time set 131
time period?timeset 132
time period < time set 132
time period > time set 132
time period is after time set 132
time period is before time set 132
time period is on or after time set 131
time period is on or before time set 131
time point 77
time point converts to time point sequence 136
time point converts to time set 136
time point has index 78
```

```
time point has number of time point kind 111
time point indicated by compound time coordinate 127
time point is on time scale 77
time point kind 110
time point kind has granularity 111
time point kind has time scale 110
time point kind of atomic time coordinate 125
time point maps to time scale 112
time point sequence 79
time point sequence corresponds to time interval 80
time point sequence has duration 80
time point sequence has first time point 82
time point sequence has last time point 82
time point sequence is from time point through time point 82
time point sequence is from time point to time point 82
time point sequence is on time scale 81
time point sequence matches time set 130
time point sequence<sub>1</sub> + integer 81
time point sequence<sub>1</sub> plus integer 81
time point sequence<sub>2</sub> = time point sequence<sub>1</sub> + integer 81
time point sequence2 is time point sequence1 plus integer 81
time point<sub>1</sub> is just before time point<sub>2</sub> 78
time point<sub>1</sub> precedes time point<sub>2</sub> 78
time point<sub>1</sub> renumbers time point<sub>2</sub> 113
time point<sub>1</sub> shares common time scale with time point<sub>2</sub> 135
time point<sub>1</sub> through time point<sub>2</sub> 83
time point<sub>1</sub> through time point<sub>2</sub> defines time point sequence 82
time point through time point specifies time period 83
time point<sub>1</sub> to time point<sub>2</sub> 83
time point<sub>1</sub> to time point<sub>2</sub> defines time point sequence 82
time point<sub>1</sub> to time point<sub>2</sub> specifies time period 83
time point<sub>2</sub> ends time point<sub>1</sub> 78
time point<sub>2</sub> follows time point<sub>1</sub> 78
time point<sub>2</sub> is next after time point<sub>1</sub> 78
time point<sub>2</sub> is renumbered by time point<sub>1</sub> 113
time point<sub>2</sub> starts time point<sub>1</sub> 78
time scale 74
time scale defines time point kind 110
time scale has granularity 75
time scale has time point 77
time scale is defined by calendar 105
time scale of atomic time coordinate 125
time scale of calendar 105
time scale of time point sequence 81
time scale on calendar 105
time scale<sub>1</sub> renumbers time scale<sub>2</sub> 113
time set 130
time set ? time period 131
time set ? time period 131
```

```
time set < time period 132
time set > time period 132
time set is after time period 132
time set is before time period 132
time set is on or after time period 131
time set is on or before time period 131
time set matches time period 130
time set<sub>1</sub> ?time set<sub>2</sub> 131
time set<sub>1</sub> < time set<sub>2</sub> 132
\underline{\text{time set}}_1 = \underline{\text{time set}}_2 130
time set<sub>1</sub> equals time set<sub>2</sub> 130
time set<sub>1</sub> is before time set<sub>2</sub> 132
time set<sub>1</sub> is equivalent to time set<sub>2</sub> 130
time set<sub>1</sub> is on or before time set<sub>2</sub> 131
time set<sub>2</sub> ? time set<sub>1</sub> 131
\underline{\text{time set}_2} > \underline{\text{time set}_1} 132
time set<sub>2</sub> is after time set<sub>1</sub> 132
time set<sub>2</sub> is on or after time set<sub>1</sub> 131
time span 215
time span of schedule 242
time stamp 121
time unit 70
time zone 120
time zone uses local calendar 120
Tuesday 172
twelfth 279
twelfth member 279
U
unique sequence 271
unique sequence has eighth member 280
unique sequence has eleventh member 280
unique sequence has fifth member 280
unique sequence has fourth member 280
unique sequence has ninth member 280
unique sequence has second member 280
unique sequence has seventh member 280
unique sequence has sixth member 280
unique sequence has tenth member 280
unique sequence has third member 280
unique sequence has twelfth member 280
unitary concept 198
upcoming day 195
upcoming hour 194
upcoming year 199
<u>UTC</u> 115
UTC of day 116
UTC time 116
```

٧

<u>VIM</u> 303

W, X

Wednesday 173

<u>week</u> 73

week period 108 whole 289

whole includes part 289

Υ

<u>year</u> 72

vear period 108

vear to date 199

vearvalue 150

year value has base duration value 152

<u>year value</u> has <u>years centennial remainder</u> 151

vear value has vears quadricentennial remainder 151

<u>vear value</u> specifies <u>vears duration value set</u> 152

vears centennial quotient 151

years centennial quotient of year value 151

years centennial remainder 151

vears duration value set 152

years quadricentennial quotient 152

vears quadricentennial quotient of year value 152

years quadricentennial remainder 151

vears quotient 151

years quotient of year value 151

vears remainder 150

years remainder of year value 151

Ζ

zero duration 60
