This OMG document replaces the submission document (finance/2013-09-02, Alpha). It is an OMG Adopted Beta specification and is currently in the finalization phase. Comments on the content of this document are welcome, and should be directed to issues@omg.org by February 28, 2014.

You may view the pending issues for this specification from the OMG revision issues web page http://www.omg.org/issues/.

The FTF Recommendation and Report for this specification will be published on June 27, 2014. If you are reading this after that date, please download the available specification from the OMG Specifications Catalog.

USE OF SPECIFICATION - TERMS, CONDITIONS & NOTICES

The material in this document details an Object Management Group specification in accordance with the terms, conditions and notices set forth below. This document does not represent a commitment to implement any portion of this specification in any company's products. The information contained in this document is subject to change without notice.

LICENSES

The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

Subject to all of the terms and conditions below, the owners of the copyright in this specification hereby grant you a fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use this specification to create and distribute software and special purpose specifications that are based upon this specification, and to use, copy, and distribute this specification as provided under the Copyright Act; provided that: (1) both the copyright notice identified above and this permission notice appear on any copies of this specification; (2) the use of the specifications is for informational purposes and will not be copied or posted on any network computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3) no modifications are made to this specification. This limited permission automatically terminates without notice if you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the specifications in your possession or control.

PATENTS

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.

GENERAL USE RESTRICTIONS

Any unauthorized use of this specification may violate copyright laws, trademark laws, and communications regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved. No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic,

electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems-without permission of the copyright owner.

DISCLAIMER OF WARRANTY

WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE OR USE. IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The entire risk as to the quality and performance of software developed using this specification is borne by you. This disclaimer of warranty constitutes an essential part of the license granted to you to use this specification.

RESTRICTED RIGHTS LEGEND

Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1) (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)(1) and (2) of the Commercial Computer Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as indicated above and may be contacted through the Object Management Group, 109 Highland Avenue, Needham, MA 02494, U.S.A.

TRADEMARKS

IMM®, MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are registered trademarks of the Object Management Group, Inc., and Object Management GroupTM, OMGTM, Unified Modeling LanguageTM, Model Driven Architecture LogoTM, Model Driven Architecture DiagramTM, CORBA logosTM, XMI LogoTM, CWMTM, CWM LogoTM, IIOPTM, MOFTM, OMG Interface Definition Language (IDL)TM, and OMG SysMLTM are trademarks of the Object Management Group. All other products or company names mentioned are used for identification purposes only, and may be trademarks of their respective owners.

COMPLIANCE

The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer software to use certification marks, trademarks or other special designations to indicate compliance with these materials.

Software developed under the terms of this license may claim compliance or conformance with this specification if and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this specification, but may not claim compliance or conformance with this specification. In the event that testing suites are implemented or approved by Object Management Group, Inc., software developed using this specification may claim compliance or conformance with the specification only if the software satisfactorily completes the testing suites

OMG's Issue Reporting Procedure

All OMG specifications are subject to continuous review and improvement. As part of this process we encourage readers to report any ambiguities, inconsistencies, or inaccuracies they may find by completing the Issue Reporting Form listed on the main web page http://www.omg.org, under Documents, Report a Bug/Issue (http://www.omg.org/report_issue.htm.)

OMG

Founded in 1989, the Object Management Group, Inc. (OMG) is an open membership, not-for-profit computer industry standards consortium that produces and maintains computer industry specifications for interoperable, portable, and reusable enterprise applications in distributed, heterogeneous environments. Membership includes Information Technology vendors, end users, government agencies, and academia.

OMG member companies write, adopt, and maintain its specifications following a mature, open process. OMG's specifications implement the Model Driven Architecture® (MDA®), maximizing ROI through a full-lifecycle approach to enterprise integration that covers multiple operating systems, programming languages, middleware and networking infrastructures, and software development environments. OMG's specifications include: UML® (Unified Modeling LanguageTM); CORBA® (Common Object Request Broker Architecture); CWMTM (Common Warehouse Metamodel); and industry-specific standards for dozens of vertical markets.

More information on the OMG is available at http://www.omg.org/.

OMG Specifications

As noted, OMG specifications address middleware, modeling and vertical domain frameworks. All OMG Specifications are available from the OMG website at:

http://www.omg.org/spec

Specifications are organized by the following categories:

Business Modeling Specifications

Middleware Specifications

- CORBA/IIOP
- Data Distribution Services
- Specialized CORBA

IDL/Language Mapping Specifications

Modeling and Metadata Specifications

- UML, MOF, CWM, XMI
- UML Profile

Modernization Specifications

Platform Independent Model (PIM), Platform Specific Model (PSM), Interface Specifications

- CORBAServices
- CORBAFacilities

OMG Domain Specifications

CORBA Embedded Intelligence Specifications

CORBA Security Specifications

All of OMG's formal specifications may be downloaded without charge from our website. (Products implementing OMG

specifications are available from individual suppliers.) Copies of specifications, available in PostScript and PDF format, may be obtained from the Specifications Catalog cited above or by contacting the Object Management Group, Inc. at:

OMG Headquarters 109 Highland Avenue Needham, MA 02494 USA

Tel: +1-781-444-0404 Fax: +1-781-444-0320 Email: <u>pubs@omg.org</u>

Certain OMG specifications are also available as ISO standards. Please consult http://www.iso.org

Typographical Conventions

The type styles shown below are used in this document to distinguish programming statements from ordinary English. However, these conventions are not used in tables or section headings where no distinction is necessary.

Times/Times New Roman - 10 pt.: Standard body text

Helvetica/Arial - 10 pt. Bold: OMG Interface Definition Language (OMG IDL) and syntax elements.

Courier/Courier New - 10 pt. Bold: Programming language elements.

Helvetica/Arial - 10 pt: Exceptions

NOTE: Terms that appear in italics are defined in the glossary. Italic text also represents the name of a document, specification, or other publication.

1 Scope

1.1 Overview

This specification is part of a family of specifications called the Financial Industry Business Ontology (FIBO).

FIBO is a modularized formal model of the concepts represented by finance industry terms as used in official financial organization documents such as contracts, product/service specifications and governance and regulatory compliance documents. This is referred to as a *Business Conceptual Model* as distinct from models or descriptions of data or IT implementations.

The scope of *finance industry* encompasses a broad range of organizations that manage money, including credit unions, banks, credit card companies, insurance companies, consumer finance companies, stock brokerages, investment funds and some government sponsored enterprises.

This particular specification defines the **Foundations** module of FIBO: a set of business concepts which are intended to support the financial industry terms semantics presented in other FIBO specifications.

Foundations is itself segmented into a number of models or ontologies.

The FIBO Foundations models define general concepts that are not unique to the financial industry, but needed to help define the financial concepts. FIBO Foundations therefore includes a number of basic legal, contractual and organizational concepts, among others. Concepts which are available in other industry standards are not included, but in some cases a "Proxy" concept is included for reference, for example for address and country concepts. The rationale for including these is two-fold:

- Concepts in the financial industry are generally specializations of more general, non-financial concepts such as
 contracts, commitments, transactions, organizations and so on, These are included in FIBO Foundations so that
 specializations of them may be defined in other FIBO specifications;
- Properties of financial industry concepts frequently need to be framed in terms of relationships to non-financial concepts such as countries, jurisdictions, addresses and the like. These are included in FIBO Foundations so that properties in other FIBO specifications may make reference to them.

FIBO concepts are documented using two forms of definition:

- 1. a structured ontology specification of the concept, and its relationships to others, represented using the Web Ontology Language (OWL).
- 2. natural language definitions which represent the concepts in natural language using the vocabulary of the finance industry.

This specification covers both the content of the models, and the underlying architecture employed for producing and presenting the model.

A number of informative annexes are provided to assist potential users with adoption and implementation of this and other FIBO specifications.

1.2 Applications and Uses of FIBO

One of the key benefits of FIBO with respect to data, message or reasoning metamodels is that it can provide a semantic anchor firmly rooted in the concepts as understood and used by people in the finance industry. FIBO enables the creation of logical data models such that those logical models derive their formal semantics from FIBO.

FIBO supports the derivation of ontologies to support semantic reasoning and querying applications. Since FIBO itself is framed using the formal constructs of the OWL language, such operational ontologies may be derived directly from the FIBO conceptual ontologies, with adaptation as necessary to support any application specific constraints.

FIBO allows disambiguation of new and existing regulation. To the extent that regulatory requirements reference the formal concepts in FIBO, terms referred to in these regulatory requirements, or in reports that are mandated, would be semantically unambiguous.

One important goal of FIBO is for the formal business definitions to be used in legal documents such as contracts, terms and conditions of sales and payment, IP protection, compliance reports; and to underpin less formal language used in advertising and customer-facing websites.

The business terms and definitions in this specification may be used as a reference model to which firms would tie their own proprietary models (semantic models or ontologies); and also as a catalog for all of the relevant data models.

1.3 How FIBO is Different from Operational Ontologies

Intended Audiences: Technical modellers, data architects

An ontology, regardless of how it is to be used, sets out formally a representation of items in a real-world domain of discourse. There are two distinct uses to which this applies:

- A business ontology (business conceptual model) as described in this specification this uses the full expressive power of the chosen notation to formally define items in the domain of discourse, without taking application technical constraints into account
- An operational ontology is constrained to operate within the parameters of a specific semantic application. Typically, this will contain a sub-set of the constructs in the business conceptual ontology, and that sub-set will typically comprise a decidable ontology.

It is necessarily the case that when something is to be used in an application, there will be technical constraints imposed upon that application. This is just as true when the application includes an ontology, as for other technologies.

The technical constraints that may apply to an operational ontology, necessarily do not apply to a business conceptual ontology. That is, the existence of some technical constraint in the application domain should not in any way influence the way in which business facts are formally captured and modeled in a business conceptual ontology.

1.4 How FIBO is Different from Data Models

FIBO can be distinguished from document/message/data/reasoning schemas of all kinds.

- FIBO models things in the real or planned world of the finance industry.
- FIBO will only contain instances of its own concepts under the specific conditions listed below. With these exceptions, FIBO contains only concepts even if those concepts have just single instances in the real or planned world of finance.
 - o Instances which are needed in order to define properties which refer to them;
 - o Classes of thing which are defined extensionally; and
 - o Examples
- FIBO is not any kind of a data, message or reasoning model, although it adds great value to these. It does not model document/message/data content or schemas optimized for reasoning.

FIBO will not include concepts about the structure of content, messages, information or data, even if that data is in turn about the finance industry.

The FIBO model, is referred to here as a "Business Conceptual Model", corresponding to Level 2 of the Zachman Framework for Information Architecture.

The distinctions between the scope of the FIBO model, and that of both logical and physical models, are further described in Annex C.

1.5 Definitions

The human readable definitions have been constructed by and with the input of business subject matter experts.

Many definitions have been derived from definitions of data elements corresponding to those terms in industry data or messaging standards. These have been adapted where necessary to ensure that they are descriptive of the thing or fact itself and not of data elements for data about those things or facts, and have then been reviewed by industry subject

matter experts to ensure that such adaptation accurately captures the sense of the business concept. In cases where the definition in a data or message standard was incomplete, context-specific or tautologous, a fresh definition was framed by the industry subject matter experts who participated in these reviews, or a third party definition was proposed and adopted.

1.5.1. Definitions Policy

In some cases, definitions have been obtained from third party sources. The policy for arriving at definitions for the FIBO industry terms was as follows (and remains so for future iterations and extensions):

- 1. In the absence of a definition endorsed by the subject matter experts for a term, "Barrons DICTIONARY OF FINANCE AND INVESTMENT TERMS, 8th Edition John Downes and Jordan Elliot Goodman" shall be used.
- 2. If a term and its acceptable definition is not in the Barrons Dictionary, then http://www.investopedia.com/dictionary/shall be the authoritative source, subject to licensing requirements being met.
- 3. If a term and its acceptable definition is not in either the Barrons Dictionary or the investopedia dictionary, then http://www.bankersalmanac.com/addcon/dictionary/ shall be the authoritative source.
- 4. If a term has no acceptable definition in these Financial Industry sources or does not exist in these Financial Industry sources then http://www.merriam-webster.com shall be the authoritative source.
- 5. When there is a conflict with the definition of a Financial Industry term with the same term in another Industry, the Financial Industry definition will be used within FIBO.

In all cases the source from which the definition was obtained, or from which it was adapted, is recorded in annotation metadata for that concept.

2 Conformance

2.1 Overview

This clause defines conformance points for the following types of artifacts:

- Technical applications of FIBO such as logical data models, XML schemas, operational ontologies, code, and other technical artifacts
- Extensions of FIBO
- Representations of FIBO for business consumption
 - In diagrams
 - o In spreadsheets or tables

Conformance of technical applications of FIBO is the most important conformance point, because it addresses the core issue of what it means to conform to the ontologies that FIBO defines. In comparison, conformance of extensions and representations, while still important, are somewhat secondary concerns.

Note that in addition to conformant applications, there are a number of scenarios in which someone may make use of the FIBO ontologies as a business conceptual model while applying their own design to meet their requirements. It is not possible to define specific conformance points for each of the possible ways in which one may legitimately develop a conventional database application or an operational OWL ontology that would be a good application. The non-normative annex [Annex E] describes a number of acceptable model architectures which may adequately reflect the material in FIBO Foundations and any of the other FIBO specifications.

2.2 Conformant Technical Applications of Model Content

Technical applications of FIBO content are logical data models, XML schemas, operational ontologies, code artifacts, and other technical artifacts that purport to conform to FIBO.

2.2.1 Assessing Model Conformance

Given that a technical application includes a set of information elements some of which correspond to the concepts in FIBO, then the application is FIBO Model Conformant if and only if:

- At least one of those information elements corresponds to a concept in the FIBO ontology for which conformance is claimed
- The application does not permit actual data to exist which would not be valid set of instances of those corresponding FIBO concepts: in other words if the data is represented as a set of individuals of the corresponding FIBO concepts then they will constitute a valid FIBO model with no contradictions

It is permissible for the information elements to have additional information or to be more constrained than those in FIBO.

2.2.1.1 Full FIBO Foundations Model Conformance

If a technical application is FIBO Model Conformant with the complete set of FIBO Foundations ontologies, then the application satisfies Full FIBO Model Conformance.

2.2.1.2 FIBO Ontology Model Conformance

If a technical application is FIBO Model Conformant with a particular FIBO Foundations ontology, then the application satisfies FIBO Ontology Conformance for that particular ontology. There is thus a separate compliance point for each ontology in Clause 10.

2.2.2 Assessing FIBO ODM Conformance

An extension of FIBO is FIBO ODM conformant if it is expressed in ODM (the OMG Ontology Definition Metamodel) and also restricts itself to using only the sub-set of ODM modeling constructs defined in the Architecture clause of this specification (8)

If the technical application is not an OWL ontology, then by definition the application is not FIBO ODM Conformant.

2.3 Conformant Extensions of FIBO Content

This definition of conformance points applies both to extension of the model content for use locally and to the preparation for submission of new model content for FIBO itself. The following conformance points may be asserted for each ontology that extends FIBO itself:

- FIBO-Full Extension in ODM: Satisfies FIBO Extension Conformance (see below) and FIBO ODM Conformance
- FIBO-Full Extension in OWL: Satisfies FIBO Extension Conformance (see below) and OWL2 Conformance

In turn, for FIBO Extension Conformance an ontology must satisfy FIBO Model Conformance (see 2.3.1) and the rules in the following three sub-clauses related to labeling, model consistency and relationship to subject matter.

2.3.1 Labeling

Business-facing labels shall be provided for all named model constructs. These labels must conform to the following formal requirements:

- Labels shall use normal English expression including spaces and punctuation, using lowercase except for proper nouns.
- Labels shall represent a plain English name (in US English spelling) which is that most commonly used by the finance industry.
- Labels do not need to be unique across the model.

• At least one business-facing label shall be present which is not in the form of, or contain, acronyms (including business acronyms) except where these are the only means by which the concept may be referred in the business domain (for example "CDO Squared").

2.3.2 Model Consistency

Reasoning is the mechanism by which the logical assertions made in an ontology and related knowledge base are evaluated by an inference engine. A logical assertion is simply an explicit statement that declares that a certain premise is true. Such assertions, taken together, form a logical theory, and a consistent theory is one that does not contain any logical contradictions. This means that there is at least one interpretation of the theory in which all of the axioms contained therein are provably true. The logical assertions expressed in the FIBO Foundations ontologies have been checked using multiple inference engines, designed specifically to support OWL 2, for internal logical consistency (*i.e.*, for consistency within that single ontology), and for logical consistency with imports closure (meaning, consistency including all axioms in any imported ontology in addition to those in the single ontology in question).

In order for any extension to FIBO to be conformant, it must be verified as being logically consistent (internally and with respect to imports) in addition to syntactically correct according to the OWL specifications. Examples of reasoning engines that can be used to verify logical consistency of an OWL 2 ontology are discussed in an article on Wikipedia¹. Members of the OMG Ontology Special Interest Group (ontology@omg.org) can also make recommendations for tooling that might assist FIBO users in verifying their extensions.

Issue FIBOFTF2- Additional conformance wording for FIBO extensions.
19:

In addition to being logically consistent, a conformant FIBO extension must be a conservative extension of each FIBO ontology that it imports i.e. the extension must not prove new logical assertions about the concepts defined in the imported ontologies. More formally, any logical assertion regarding concepts drawn exclusively from the vocabulary of an imported FIBO ontology is provable in a conformant extension if and only if it is provable within the imported ontology. This condition ensures that conformant FIBO extensions use the concepts defined in the imported FIBO ontologies without changing their meanings by narrowing or constraining them and supports composability of conformant FIBO extensions. As for logical consistency, reasoners can be used to verify that an OWL2 ontology is a conservative extension of an imported ontology but in general it is a more difficult problem so reasoners will take longer to determine this. Pragmatic guidelines like prohibiting restrictions on imported concepts can help ensure that extensions are conservative but in general it is possible to restrict imported concepts indirectly in subtle ways and so a reasoner should be used to verify conformance.

2.3.3 Relationship to Subject Matter

In any extension to FIBO model content each model element which is a class, an object property or a datatype property shall correspond to some item in the real world. No model element shall refer to some technical construct such as a database field, internal identifier, database key and the like.

An exception is made for information constructs which are themselves important and publicly shared parts of the business domain, such as publicly issued identifiers, security identifiers, ratings codes and the like. In each such case, there shall be some formally identified scheme in which the code in question is defined.

A suitable test for types of "Information" to be considered real is whether that information is publicly shared or, if private, made available across the business supply chain. Examples include Legal Entity Identifier, securities prospectuses, published indices, interest rates.

2.4 Conformant Business Presentation of Model Content

There are two conformance points for presentation of FIBO content:

FIBO Business Diagram

¹ http://en.wikipedia.org/wiki/Semantic reasoner

- FIBO Business Table

Any tool which asserts support for one or other or both of business presentation conformance points must be able to import the available FIBO content in at least one of the available serialization formats (UML XMI, ODM XMI or OWL), and produce diagrams and/or tables which conform with the requirements defined for the conformance point.

2.4.1 General Requirements

It is a requirement of this specification that content of the models is made available to people in the business domain in one or more of a set of diagrams and tables which are described in this specification.

A presentation of FIBO model content is not a conformant FIBO Business Presentation (i.e. a conformant FIBO Business Diagram or a conformant FIBO Business Table) if the only means for the reader to view the model's terms, definitions and relationships is one which requires some formal understanding of some model language such as UML or OWL, beyond the knowledge conveyed by the annexes to this specification. For the avoidance of doubt, a non-conformant business presentation is any format which contains symbols, whether diagrammatic or textual, which have a meaning other than the meaning which a reasonably educated but non-technical person would ascribe to those items

2.4.2 Business Diagram Conformance

OWL features such as restrictions on properties or classes, where these are present in the model content, shall be rendered in some way that communicates their business intent without reference to the way in which the OWL syntax represents these constructions.

OWL constructs shall be represented by simple constructs which do not require specialist technical training, such as boxes, arrows and lines.

All notation on all diagrams shall only represent features of OWL, except where this is clearly identified as additional annotation (intended to enhance an understanding of the business content of the model and not part of the model itself).

In diagrams generated from OWL tools or other non UML based tooling, no features shall be present which do not represent some feature of OWL except where these are clearly identified as visual decorations intended to enhance an understanding of the business content of the model.

If UML Generalization notation is used, this shall be laid out with the "arrowhead" pointing vertically upwards, in either the vertical tree style or direct style of routing. Generalization relationships may also be represented using more intuitive, non UML notations, in which case this requirement shall not apply.

2.4.3 Business Table Conformance

This sub clause concerns two kinds of tabular presentations: Basic Table and Extended Table. Conformant FIBO Business Tables may be rendered as spreadsheets or as textual documents in a tabular layout.

2.4.3.1 Basic Table

A conformant FIBO Business Table using the "Basic" tabular format shall show only the following entries:

- Term (preferred label for concept)
 - o Classes and properties may be in the same column or different columns
- Definition
- Synonym

These shall be labeled as such.

This table shall only show those constructs from the FIBO model content which represent meaningful business concepts, and not the additional constructs which deal with the set theoretic logic of the model. That is, the basic table shall show only (differentiating between them):

- Class
- Relationship Property
- Simple Property

2.4.3.2 Extended Table

A conformant FIBO Business Table using the Extended Tabular format shall conform with the following requirements:

The extended table shall have column entries for each of the basic model features, as follows:

- Term
- Definition
- Synonym
- Range of Simple Properties (titled as "Simple Type")
- Range of Relationship Properties (titled as "Related Thing")
- Property type
- Super (class or property) (can be labeled as "Parent")
- Disjoints (labeled "mutually exclusive")
- Additional metadata may or may not be shown, at the discretion of the modeler and as appropriate to the intended usage (for example, review notes annotations).

The following model constructs shall be included in the Extended Table reports, in or near the following order:

- Class
- Union Relationships
 - labeled "In Union" when reported for members of the union
 - labeled "Union Of" when reported as the relationships from the Union Class
- Relationship Property
- Simple Property
- Union Class
- Individuals
 - 'typeOf' relationships from Individual to Class (labeled "type of")
- Annotations there are no specific requirements for how these are presented.

Object Properties and Datatype Properties shall only be included once in all reports across the model, and this shall be for the class which is the domain of that property.

The intention of these requirements is that the report shows each type of fact, once only and in a logical order.

3.3 Changes to Adopted OMG Specifications

This specification does not change or replace any OMG specifications. It does, however, depend on pending changes to the Ontology Definition Metamodel (ODM), in support of OWL 2 and RDF 1.1.

4 Terms and Definitions

For the purposes of this specification, the following terms and definitions apply.

Content

Definition: Subject matter or meta-content.

Business conceptual model

Definition: A model which represents and only represents <u>business subject matter</u> without reference

to the design of any solution or data model representation.

Business publication

Definition: Representation of a <u>subject matter view</u> in a form that is understandable and usable by

business users.

Example: Text document, web page, audio recording, interactive search dialog

Business subject matter

Definition: Subject matter that defines and describes the kinds of people (and the roles they play), or-

ganizations and other things that an enterprise has to deal with in the course of its operational business, regardless of how this content is presented to the people in the organiza-

tion (e.g. in text documents, web pages, audio broadcasts).

Example: Business concepts, such as: OTC derivative, business day

Example: Relationships between business concepts, such as: swap transaction has ISDA confirma-

tion

Example: Constraints, such as: Each ISDA confirmation is of exactly one swap transaction

Example: Descriptions, such as: ISDA is the largest trade organization of participants in the OTC

derivatives market.

Example: Business processes (defined in terms of the business concepts), such as:

If a Disputing Party reasonably disputes the Value of any transfer of Eligible Credit Support, then the Disputing Party will notify the other party not later than the close of busi-

ness on the Local Business Day following.

Note: Business subject matter is mainly about kinds of thing, but may include individuals, in

three roles: (1) as one-of-a-kind things referenced in the subject matter, such as *ISDA*, *Dodd-Frank Act*, *EC Treaty*; (2) As types defined by enumeration, such as the currencies

in which a trading business maintains accounts; (3) in examples.

Note: Business subject matter is usually scoped by area of business jurisdiction (or something

similar), such as, say, derivatives trading. The business subject matter is about the busi-

ness of derivatives trading.

Other areas of responsibility in the enterprise have different subject matter. For example, the IS department's subject matter includes information models of things in the operational business (including derivatives trading). The finance department's subject matter in-

cludes financial models of things in the operational business.

From the derivatives trading perspective (the relevant parts of) these information and fi-

nancial models would be considered meta-content.

Business subject matter view

Definition: Subset of <u>business subject matter</u> that is intended to be presented in some <u>business publi-</u>

cation.

Example: Concept definitions; relationship definitions with constraints.

Extension

Definition: The membership of some class of thing. This is distinct from its <u>intension</u>, that is the

properties intrinsic to that class of thing. In applying the <u>intension</u> of some class to some collection of individuals, one arrives at the <u>extension</u> of that class for that collection.

Extensional

Definition: Logic explicable solely in terms of extensions; ignoring differences of meaning that do

not affect the extension.

Extensional Definition of Class Membership

Definition: The definition of membership of a class by direct articulation of those members (that is,

by articulation of the Extension of that class.

Intension

Definition: The properties intrinsic to some class of thing.

Intensional

Definition: Logic (of a predicate) incapable of explanation solely in terms of the set of objects to

which it is applicable; requiring explanation in terms of meaning or understanding.

Intensional Definition of Class Membership

Definition: The definition of membership of a class according to properties intrinsic to members of

that class.

Meta-content

Definition: Information about subject matter

Example: Control information, such as: date and author of last update, external source, owner

Example: Connection of subject matter items to content outside the subject matter scope, such as da-

ta model elements that correspond to them (and point to the storage of instance data).

Model-Theoretic Conformance

Definition: The manner in which some model conforms with some theory about what it is intended to

model and how it is intended to model it.

Ontology

Definition: A formalization of a conceptualization. For the purposes of this specification the formali-

zation is in OWL, using ODM as a means to render this, and the conceptualization is that

of business subject matter.

Operational Ontology

Definition: An <u>ontology</u> which is intended for use within some application.

Subject matter

Definition: Information about things in the universe of discourse; the essential facts, data, or ideas

that constitute the basis of spoken, written, or artistic expression or representation; often: the substance as distinguished from the form especially of an artistic or literary produc-

tion.

Taxonomy

Definition: A set of terms which stand in some classification relation to one another.

Terminology

Definition: The overall disposition of ontologies of concepts and vocabularies of terms, in relation to

one another.

22

Financial Industry Business Ontology Foundations Beta

Vocabulary

Definition:

A set of words, each giving one or more formal definitions which apply to a meaningful concept that is referred to by that word.

5 Symbols and Abbreviations

5.1 Symbols

There are no symbols introduced by this specification.

5.2 Abbreviations

The following abbreviations are used throughout this specification:

- OWL Web Ontology Language
- ODM Ontology Definition Metamodel
- RDF Resource Definition Framework
- SME Subject Matter Expert
- UML Unified Modeling Language
- URI Uniform Resource Identifier
- URL Uniform Resource Locator
- XMI XML Metadata Interchange
- XML eXtensible Markup Language

Additional symbols and abbreviations that are used only in annexes to this specification are given in those annexes.

6 Additional Information

6.1 How to Read this Specification

6.1.1 Audiences

This specification has the following audiences:

- The standards community
- The finance industry business community
- The regulatory community
- Technical architects
- Semantic Modelers

Each clause opens with a statement identifying the intended audience for that clause. The language in that clause is then framed appropriately for readers from that audience. Where "Intended Audience" is not stated the material in that clause is intended to be comprehensible to all general readers.

6.1.1.1 Standards Community

This audience is intended to be able to follow and validate the way in which this specification sets out the arrangements for the production and maintenance of model content, and the production of business facing reports and diagrams representing parts of that content.

6.1.1.2 The Finance Industry Business Community

As noted in the clause on conformance (2) this specification includes detailed requirements for the production of diagrams and reports that are intended for consumption by business subject matter experts. This specification also contains material addressed at this audience, this being an informative annex on "Interpreting Model Content". This audience is not intended to read and understand the remaining parts of this specification.

6.1.1.3 The Regulatory Community

As for Finance Industry Business Community.

6.1.1.4 Technical Architects

These include but are not limited to:

- Tooling vendors and developers
- Other content providers / enriched content providers
- Business Analysts anyone who use the model on site, whether they are a modeler, a metadata analyst, etc.
- o Technology Management

The bulk of the "Architecture" clause is intended to be read and understood by these audiences and by the 'Semantic Modelers' audience.

6.1.1.5 Semantic Modelers

Much of the material in this specification is intended to be read and understood by semantic modelers. This includes the 'Conformance' clause (2), the 'Architecture' clause (8) and the non normative Annex D on implementing and extending this model and proposing new model content.

The Semantic modeler audience is not the same as the technical audience, although some individuals may possess skills in both. clauses of this specification which are written for a semantic modeling audience do not require any training in any formal technology in order to understand and act upon their contents. These clauses do require a clear understanding of semantics and formal logic. It is not necessarily the case that technical readers are expected to be able to read and understand all aspects of the semantic modeling material. It should also be noted that some terms which have specific meanings in one or more technology environments, may have different (or often only subtly different) meanings to the semantic modeling audience. Where both semantics and technical audiences are intended to read a clause, care has been taken to try to use all of the applicable terms and qualify words which have multiple different usages to these audiences.

6.2 Acknowledgements

6.3 Interpreting the Business Model Content

Intended Audiences: Business Subject Matter experts

6.3.1 Introduction

The model content is intended by read and understood by business domain experts with knowledge of business entities and legal concepts. It requires no knowledge of modeling theory, technical modeling languages, technology development or data modeling.

The following knowledge is required to interpret the model content:

- Set theory
- Logic
- Business (commerce, law, finance)

6.3.2 The Model

6.3.2.1 What the Model Contains

The model described in this specification contains elements called 'Things', Simple Properties about those things in the form of unstructured information, and Relationship Properties in the form of relationships between one 'Thing' and another. Things, Simple Properties and Relationship Properties all have as a minimum the definition for the term that they represent, plus additional information on usage, review history, sources of terms and definitions and so forth.

6.3.2.2 Model Views

Whereas the information given in this specification conveys all of the model content, the diagrams and tables that are created for a business audience will not show all of this information, but only a sub-set. This sub clause describes those formats and views, and is to be read by a business audience to understand what those views show. This sub clause contains no technical language about OWL or other modeling constructs but uses the plain English alternative terms for those concepts.

The content of the model is rendered in two basic forms: visual information in the form of diagrams, and textual information in the form of tables. The diagrams are available in varying levels of detail and are created to show different sets of terms and relationships across or within sections of the model. The textual information is created as web based tabular reports and as spreadsheets. These contain basic information of term, definition and synonym and in some cases will contain additional information about the types of thing or the types of information to which facts in the model refer. Business tables and spreadsheets do not show relationships between relationships as such information would be difficult to visualize in the tabular format.

Diagrams and tables reflect the information retained in the underlying model repository directly. For example, if two 'Thing' elements have a relationship between them and they appear on the same diagram, the relationship between them will always appear.

6.3.2.3 Business Diagrams

Business diagrams reflect any set of terms in the model, within or across sections of the content. These may be rendered with varying levels of detail. Diagrams created during reviews of the subject matter will typically contain a greater range of terms than diagrams created for presentation to the wider community of potential users.

6.3.3 Interpretation

The model conveys 'Things' and 'Facts'. Facts are in two forms:

- 'Simple Properties': these are a statement about something which is framed in terms of some simple type of information, such as textual entries, yes/no answers, dates, numbers and selections of textual information
- 'Relationship Properties': these are a statement about something which is framed in terms of something else, that other thing also being framed as a kind of 'Thing'.

In addition, there are relationships which represent additional set theory concepts, notably logical unions, mutual exclusivity.

Each 'Thing' also has a 'Parent' relationship, with the sense of 'is a', shown as an upward point arrow on the diagrams. This relationship indicates that the thing from the non-arrowed end is "a kind of" the thing at the end with the arrow.

These concepts are described in the sub clauses which follow.

6.3.3.1 Thing

A Thing is a set theory construct. This is shown on the diagrams as a box with a name. On some diagrams, additional textual entries in the box show the Simple Properties about that thing.

A Thing is defined as the set of individuals which are defined according the facts (properties) given for that kind of thing. Membership of the set is defined in the sense that any individual in the world of which the stated facts are true or applicable, is a member of that set. In terms of logical theory, these sets are defined intensionally. It is also possible to define a set explicitly as a list of its members (in logical theoretic terms, an extensional definition) but this is not used in practice in the model.

6.3.3.2 Inheritance: the Parent 'is a' relationship

Each Thing in the model has one or more parent Things. The relationship between the Thing and its parent may be interpreted as an 'is a' form of relationship, meaning that the thing of which the parent relationship is shown is a kind of the thing to which the arrow in the Parent relationship is pointing.

This relationship formally indicates that the thing that has the Parent, inherits all of the facts about that parent. In addition, this relationship is transitive, meaning that the parent relationships of the parent are passed on to the child term. For example, if a share is a security and a security is a transferable contract then a share is a transferable contract.

The relationships of this type create a formal inheritance structure called a Taxonomy. Taxonomies in this sense may be single inheritance (as is often seen in technical model designs) or multiple inheritance. In the FIBO models these are multiple inheritance, meaning that types of thing (such as types of contract) may be classified in more than one way. So for example an interest rate swap is both a swap and an interest rate derivative.

As an example of multiple inheritance, one might say that in terms of the Linnaeus Taxonomy of Species, a whale is a mammal, while one may also create a set of taxonomic classifications based on habitat, in terms of which a whale may also be a marine animal.

On a technical note, the Parent relationship is functionally identical to the relationship known as 'Generalization' in the UML modeling language.

6.3.3.3 Simple Properties

Simple Properties are assertions about things in a class, which may be framed in terms of some simple type of information.

Types of information about which Simple Properties are asserted are:

- Text
- Date
- Number
- Whole number
- Yes/no answer
- Selection of textual descriptors

To a technical person these may easily be identified with what are called 'datatypes'. However these represent the types of information not data as such. A special case is the selection of possible answers - this refers to a list of entries (see Selection Lists).

6.3.3.4 Relationship Properties

A Relationship Property is defined as a fact about something which is framed in terms of a relationship to some other thing.

These are indicated on the diagrams as a blue arrowed line. Some diagrams additionally show a box attached to this blue line; this is used to indicate relationships between those Relationship Properties, which are shown as lines between those boxes.

Relationship Properties are of the form subject-relationship-object where the subject is the Thing from which the line is drawn and the object is the thing to which the blue arrow points.

The label on the line is the verb itself, while the attached box indicates the full name of the Relationship Property. Relationship Properties are unique across the model and each belongs to one Thing only.

There are additional pieces of information about these Relationship Properties, such as whether they are symmetric, transitive and so on. The use and interpretation of these refinements to Relationship Properties are beyond the scope of this explanatory sub clause.

6.3.3.5 Logical Unions

Logical unions indicate that any individual which is a member of any of the classes of 'Thing' of which the union is a union, are members of that union.

The Union is shown as a box on the diagrams, similar to the boxes used for classes of 'Thing' but without the coloring given for archetypes (no Union has an archetype), that is these have the default gold box appearance of an OWL Class.

Membership of the union is indicated by a purple relationship similar in appearance to the Parent / 'is a' relationship. The Union (set) shown at the top of the arrow is thereby indicated as being a logical union of all the sets indicated as classes of Thing at the bottom of the purple arrows.

Relationship Properties may refer to unions in the same way that they refer to other classes of Thing.

6.3.3.6 Mutually Exclusive sets

Given that each thing is a set of potential members defined by their properties (facts), it is possible for any one thing in the world to be defined as being a member of more than one set, if the properties asserted for one set are not related to the properties asserted for another set.

Where membership of one set necessarily precludes membership of another set (that is, where a set is defined such as to specifically exclude members of another set), this is shown by a red line on the diagrams, labeled 'mutually exclusive'.

Where classes of 'Thing' are not indicated as being mutually exclusive (or have parents which belong to classes of Thing which are mutually exclusive), then any individual in the domain of discourse (the world) may belong to both sets.

This is formally known as a 'disjoint' relationship.

6.3.3.7 Relationship Properties hierarchies

Relationship Properties are themselves disposed in a hierarchy similar to that given for the classes of 'Thing'. These are indicated on more advanced diagrams by a green upward pointing line in the same style as the Parent relationship line. The Relationship Property to which the arrow points represents a more general meaning, of which the Relationship Property at the bottom of the relationship represents a narrower definition of the same meaning.

The narrowing of these meanings frequently occurs in conjunction with the narrowing of the meanings of classes of 'Thing' in the taxonomy. For example, types of bond are classified (a narrowing or specialization of the meaning of 'bond') according to, among other things, a narrowing of the relationship 'issued by' with the latter relationships being distinguished form one another by the nature of the kind of party which is the issuer.

This is formally known as a "sub property of' relationship.

6.3.3.8 Inverse relationships

These are only shown on diagrams that show the Relationship Properties with their boxes, i.e. diagrams that show relationships between relationships.

Relationship Properties in the model are all one-directional, by virtue of their being framed as 'subject-verb-object' triples. In the business domain, meaningful terms and definitions may exist in either direction between one class of thing and another (for example, a bank has a customer versus a person has an account at the bank.

These are indicated as a red dotted arrowed line between one relationship and the relationship to which it is the inverse.

In theoretical terms, this relationship only applies between relationships which are known as 'functional' relationships. An explanation of this is beyond the scope of this sub clause.

6.3.3.9 Selection Lists

A list of possible entries for a simple type is displayed as a box on the diagrams, with a list of the possible entries. These are displayed as text, and generally refer to lists of possible textual values for the Simple Property.

It should be noted that these do not or should not represent lists of kinds of 'Thing' - those would be represented as a taxonomy of actual things. This is an important difference between this and a data model, since many data models have similar selection lists, called 'enumerations' in the data modeling world, which may represent kinds of thing or classifications of the thing which has these as a property.

6.3.3.10 Selections of Things

This is a class or set of things of which the members are explicitly listed (in theoretical terms, an extensional definition of the class).

These are not used at present in the model but are provided for in the modeling notation.

Introduction 7

7.1.1 Reading this Standard

Technical audiences (in both conventional and semantic technology) are directed at the "Architecture" clause (8).

Business audiences (financial industry participants, regulators and others) are directed at the sub clause on interpreting model content (6.3) and the model content itself in Clause 10.

The business content defined in this standard is intended to be presented both in a business-facing format and in a complete, technical format. The latter is intended for consumption by technical and standards audiences only. This specification defines the content of the standard and the ways in which it is to be presented to business readers.

Usage Scenarios

Intended Audiences: Technical implementers (conventional and semantic technology); technology management

The model defined in this specification is intended for use as a business conceptual model.

The uses envisaged for the model are as follows:

- Model driven development
 - Of database schemas
 - Of message schemas
 - Of common messaging across a business unit or organization
- Semantic Technology development
- Integration of systems and/or data feeds

In addition, the model may be extended locally to extend the scope of what is modeled, prior to using such local extensions in any of the above usage scenarios.

7.2.1 **Model Driven Development**

Model Driven Development refers to the top town development of technical artifacts starting with a high level, business view of the requirements (for programs) or the data semantics (for data).

The model defined in this specification is intended to be situated within any model driven development framework, as a conceptual model and potentially extended locally with additional concepts. This is the case whether the development is for databases, messages or a combination of the two.

Analysis of the model and metadata provided may enable the automation or partial automation of the production of logical data models, or at least of a candidate starting point for the development of the logical data model prior to the addition of keys and other database requirements.

The model described and presented within this specification supports multiple inheritance between classes, whereas most logical data models would be developed using a single inheritance taxonomy (as this is often a constraint on the logical or physical models development). This model will contain metadata which defines, for multiple inheritance taxonomies, Such information can be interrogated to extract from the model a suitable single inheritance taxonomy appropriate to the requirements of the development.

If this model is used within a UML tool, users may create formal mappings between logical data model constructs and the semantics corresponding to these in the FIBO model content. This simplifies the validation and verification of technical data model artifacts.

7.2.2 Semantic Technology Development

As part of this specification, model content is made available in the Web Ontology Language (OWL) format, which is the format used in semantic technology applications.

However, semantic technology developers should be aware that the physical and technical constraints, which rightly apply to semantic technology applications, have not been imposed, since its primary purpose is to serve as a conceptual model at the business level.

Similarly, it should be noted that in defining the formal meanings of terms in the business domain, most of those meanings are "grounded" with reference to legal constructs, accounting constructs and so on. This may or may not correspond to instance data in the application. Typically a semantic technology application, like any other application, will operate on actual data.

There is therefore a distinct difference between the terms defined in this model to satisfy the requirements of a business conceptual model, and the terms required or to be found in an ontology that would be used in a semantic technology application.

Semantic Technology developers will therefore need to extract from the model content, some suitable and decidable subset of that content.

This specification does not detail exactly how to derive decidable sub-sets of the content, such as OWL-DL. It is left to the semantic technology developer to make the necessary transformations.

Some of the metadata provided with this model may assist in this.

7.2.3 Integration of systems and/or data feeds

The simplest application of this conceptual model is to simply use the terms as a common point of reference when comparing terms within different logical or physical data models. This would be of value for example when integrating different systems.

Many systems may not have a formally stated ontology for the data elements that they use, or the database schema may be considered to be the only record of the meanings of the terms therein. Typically, whenever two or more systems need to be integrated, there is a time consuming and almost open ended "mapping" exercise in which the meanings of each of the terms in each of the databases or message schemas involved in the integration, are guessed and perhaps written down.

In reality, even when the intended meanings of the elements in each database and message schema are known, there is not an easy one-to-one mapping between one system and another. This is typically the result of good design: the more the designs have made use of reusable common data structures, the more efficient that design is, but correspondingly the less explicit is the semantics of the terms.

In an integration project that brings together data elements from more than two systems or data feeds, the number of mappings that need to be carried out between one system or feed and another is a geometrical function of the number of such data sources and feeds. In order to have a mapping exercise which is only arithmetically related to the number of data sources and feeds, it is necessary to have a single "hub" of terms which are able to be used as a common point of reference between each of the data models.

While this can often be achieved using a single data model, in practice the limitations on data models (such as single inheritance taxonomies in many cases, though not all) mean that no one model can be found against which all terms in all data models and feeds may be cross referenced. The model presented as part of this specification, being a semantic model, contains full definitions of the meaningful concepts which may be referred to by any of the data elements in the data sources or feeds that need to be integrated, as long as this model may be extended locally to cover areas of scope which are not part of the current specification.

8 Architecture

Intended Audience: Technical, including Enterprise and Information Architects, Implementers.

This clause provides an overview of the ontology architecture and modeling strategies used to develop the Foundations ontology.

- Usage and restriction of the Ontology Definition Metamodel (ODM) standard
- Notional architecture and intended use of the Foundations ontologies
- Application and adaptation of semantic modeling techniques and notations for business presentation.

The technical content, including diagrams, incorporated in Clause 10 of this specification, was generated from the same models used to generate the RDF/XML serialized OWL, further ensuring correctness and completeness of the specification itself.

8.1 Ontology Definition Metamodel (ODM) Usage and Adaptations

8.1.1 Introduction

The model content is developed and maintained using the Unified Modeling Language as a modeling tool framework, but with all model content built using the formal constructs of the Web Ontology Language (OWL). This is achieved using the OMG's Ontology Definition Metamodel (ODM) specification.

The Ontology Definition Metamodel (ODM) specification provides a means to represent OWL constructs using UML tools. This is achieved using UML's extension capability called 'profiles' for OWL and for RDF Schema. The ODM UML Profiles define a number of stereotypes which apply to standard UML metaclasses and may be used to represent OWL constructs in a consistent and meaningful way. The FIBO specifications use an explicit subset of ODM as detailed in Table 8.1 below. This subset eliminates some of the flexibility that ODM provides in exchange for consistency in terms of the graphical notation.

8.1.2 ODM Constructs Usage

Table 8.1 shows the RDF, RDF Schema and OWL model constructs, the names of the ODM stereotypes and their corresponding UML base classes. Where many stereotypes are listed, the base classes apply in order.

Full details of these stereotypes and how they are used are given in the ODM Specification.

Table 8.1. ODM Constructs Usage

Construct	Stereotype	UML Base Class or Element
RDF/RDF Schema Constructs		
Vocabulary Reference	references	Dependency
Namespace Definition	namespaceDefinition	InstanceSpecification
Datatype	rdfsDatatype	Class

Annotation instance	annotationFact	Dependency

8.2 Ontology Architecture and Namespaces

The ontology architecture for FIBO is designed to facilitate reuse and ontology evolution to the degree possible. It is also designed to facilitate mapping to other standards, in particular, to financial industry domain standards, such as FpML (Financial Products Mark-up Language²). There are countless standards used for financial reporting, many of which are complex and lengthy, with overlap and jurisdiction-specific semantics. An approach to the foundational terminology that provides very high-level, abstract conceptual knowledge designed to facilitate mapping is an important design goal of FIBO Foundations.

Proxy concepts for Goal, Objective, Address, and Country, for example, that are included in the Foundations with little embellishment, are designed to provide hooks for mapping to the OMG's Business Motivation Model, ISO standards for Country code representations, US Publication 28 and other national postal addressing standards, and so forth. The basic building blocks for the Foundations Ontology are shown in Figure 8.1, below.

As shown in the diagram, the Foundations ontologies are divided up into a number of *modules*. For example, the Utilities module includes: a general purpose BusinessTypes.owl ontology, a general Relations.owl ontology, and an AnnotationVocabulary.owl ontology, that captures FIBO-specific annotations.

The Foundations modules will ultimately depend on (1) Basic Terminology and Ontology Metadata (in light gray in the figure), and (2) a number of external modules, representing concepts for Natural Language, Geopolitical Entities (for

² See http://www.fpml.org/.

example ISO 3166 Country codes, regional and municipal designations), Postal Addressing (from standards such as US Publication 28), and concepts defining dates, times, calendars, and schedules. A sample set of these anticipated external resources are given in the dark gray layer in the figure.

In this initial version, the Foundations standard reuses metadata definitions, as highlighted in Figure 8.1 in the Basic Terminology and Ontology Metadata layer, from:

- The Dublin Core Metadata Terms Standard
- The W3C Simple Knowledge Organization System (SKOS)
- The OMG Architecture Board's Specification Metadata Recommendation

SKOS and the OMG Specification Metadata are explicitly imported, while the Dublin Core is not-, due to the fact it is an RDF Vocabulary and only OWL ontologies may be formally imported.

Issue FIBOFTF2-27: Replace architecture block diagram.

Basic Terminology & Ontology Metadata			

Figure 8.1 Foundations Ontology Architecture

The namespaces and their well-known prefixes corresponding to external elements required for use of FIBO Foundations include the following:

Table 8-2. Prefix and Namespaces for referenced/external vocabularies

Namespace Prefix	Namespace	
rdf	http://www.w3.org/1999/02/22-rdf-syntax-ns#	
rdfs	http://www.w3.org/2000/01/rdf-schema#	
owl	http://www.w3.org/2002/07/owl#	
xsd	http://www.w3.org/2001/XMLSchema#	
dct	http://purl.org/dc/terms/	
skos	http://www.w3.org/2004/02/skos/core#	
sm	http://www.omg.org/techprocess/ab/SpecificationMetadata/	

The namespace approach taken for FIBO is based on OMG guidelines and is constructed as follows:

- A standard prefix http://www.omg.org/spec/
- The family name, EDMC-FIBO
- The abbreviation for the specification: in this case FND
- The module name
- The ontology name

Note that the URI/IRI strategy for the ontologies in FIBO takes a "slash" rather than "hash" approach, in order to accommodate server-side applications. Though not technically necessary, this specification does mandate namespace prefixes to be used. These are constructed as follows with the components separate by "-":

- The specification family name fibo
- The specification abbreviation: fnd
- An abbreviation for the module name
- An abbreviation for the ontology name

The namespaces and prefixes corresponding to FIBO Foundations ontologies are summarized in Table 8-3 for convenience. These are given in alphabetical order, by module, rather than with any intent to show imports relationships.

Table 8-3. Prefix and Namespaces for FIBO Foundations

8.3 FIBO-Based Reporting

8.3.1 Business-Facing Approach

There are a number of ways of presenting the ontology to domain experts, and the intent is to standardize two of these.

Diagrammatic Presentation

The FIBO ontologies (model) may be presented to business domain experts in a number of forms, with views that express different levels of detail and different aspects of the model to aid in understanding. Critical requirements for business-facing diagrams include limiting or eliminating technical detail while retaining it in the underlying model, and hiding, to the degree possible:

- stereotype names on diagrams, although English labels and icons may be used where important to express the meaning of a line or box,
- technical tags, such as visibility, and optionally names, on property endpoints,
- empty partitions in boxes representing classes and association classes, and

the class in an association class representation of an object, data, or annotation property.

This does not preclude the incorporation of diagramming elements to represent fundamental concepts from set theory, first order logic, etc., that are needed to understand the ontology. Other requirements for diagramming style will be forthcoming as the specification achieves broader adoptions.

An example, showing a simplified OWL diagram, is given in Figure 8.2.

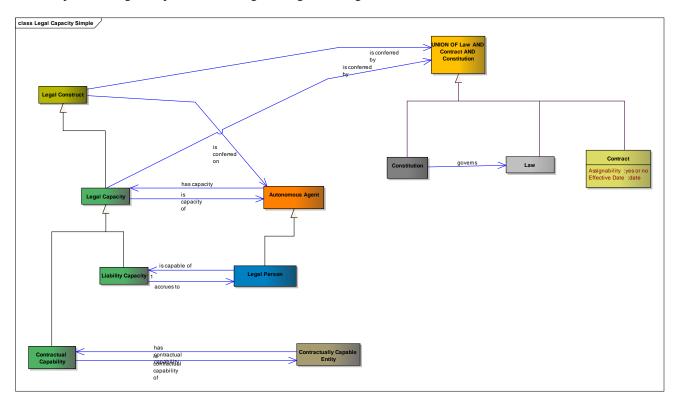

Figure 8.2 Example Business-Facing FIBO Diagram

The strategy for representation for subject matter experts may include use of color to highlight certain lines, in addition to labeling them in English, for example, by using blue lines for object properties, green lines for data properties (if they are not shown using an attribute style, inside the class box), dashed red dependency for disjointness, and so forth.

Tabular or Textual Presentation

In addition to the presentation via diagrams, there is a need to provide business domain experts with a more spreadsheet-like view of the terms, relationships, formal definitions, and other annotations in particular, for review, understanding, and use.

There are two levels of detail that shall be made available in reports. These are the 'Basic' view of Term, Definition and Synonym, and an extended view giving most or all of the same information that is seen in the diagrams. This shall include line entries for each thing and each fact (Relationship Property and Simple Property) as well as the set theory constructs and relationships modeled (unions, parent terms etc.). It is not necessary to show relationships between relationships in these tables, such as sub property hierarchies or property inverses.

The constructs shall be represented with an English language name, including spaces between words rather than camel case; those that are substantially different from their OWL language equivalents include: "Is A" for subclass relationships, "Type" for datatypes, "type of" rather than rdfType, "Simple Property" for datatype properties, "Relationship Property" for object properties, and "mutually exclusive" for disjointness relationships. These names are in US English and may be replaced in reports with definitionally equivalent labels in other natural languages and possibly additional terms that may be added to support parallel, collaborative development processes required for FIBO financial product-specific ontologies.

9 Additional Metadata

9.1 Introduction

As discussed in Clause 8, the FIBO Foundations and specifications that depend on it reuse existing metadata standards, including:

- The Dublin Core Metadata Terms Standard
- The W3C Simple Knowledge Organization System (SKOS)
- The OMG Architecture Board's Specification Metadata Recommendation

These metadata definitions are not inherent elements of RDF Schema or OWL, although the standard makes extensive use of rdfs:label in particular. This clause of the specification describes the metadata used throughout the standard and provides examples where appropriate for clarification purposes.

Issue FIBOFTF2-28: Reordering of specification metadata descriptions to account for About files

9.2 Family and Specification Metadata

The Foundations specification has a set of common metadata which is specified in this sub-clause and is given in the specification and version 'About' ontologies as described in the sub-clause on the About ontologies. This information is included regardless of whether the About ontologies are serialized as RDF/XML OWL, UML/XMI with the ODM profiles for RDF and OWL applied, or as ODM XMI.

9.2 Ontology-Level Metadata

Each Foundations ontology has a set of common metadata which is specified in this sub-clause rather than being repeated for each ontology. This information is included regardless of whether the ontology is serialized as RDF/XML OWL, UML/XMI with the ODM profiles for RDF and OWL applied, or as ODM XMI.

The use of the "sm" namespace prefix in the abbreviated IRI for the metadata term refers to the Specification Metadata ontology, as described in Table 8-2, above.

sm:specificationTitle	Financial Industry Business Ontology (FIBO) Foundations Specification
sm:specificationAbbrevia tion	FIBO-FND
sm:specificationURL	http://www.omg.org/spec/EDMC-FIBO/FND/
sm:specificationAbstract	FIBO Foundations is a set of business concepts which are intended to support the financial industry terms semantics presented in other FIBO specifications.
	The FIBO Foundations models define concepts which are not unique to the financial services industry. From these, financial industry terms in other FIBO specifications may be derived by extension. Terms are also included which may be referred to by properties of things in those specifications. FIBO Foundations therefore includes a number of basic terms about legal, contractual and organizational concepts, among others.

skos:historyNote	This version of the FIBO Foundations Specification was revised primarily to reflect comments received at the March 2013 OMG Technical Meeting in Reston and reflected in the Errata discussed at the June 2013 OMG Technical Meeting in Berlin.
	Revisions to FIBO Foundations are managed per the process outlined in the Policies and Pro- cedures for OMG standards, with the intent to maintain backwards compatibility in the on- tologies to the degree possible.
	The RDF/XML serialized OWL for the Foundations ODM/OWL ontologies have been checked for syntactic errors and logical consistency with Protege 4 (http://protege.stanford.edu/), HermiT 1.3.7 (http://www.hermit-reasoner.com/) and Pellet 2.2 (http://clarkparsia.com/pellet/).
sm:addressForComments	http://www.omg.org/issues/

Issue FIBOFTF2-28: Reordering of specification metadata descriptions to account for About files and additional text.

9.3 Module Metadata

Every module will have unique metadata specific to that module, as given in Clause 10, below. Additionally, every ontology will include curation metadata. Explicit use of the MIT License³ for software (including OWL ontologies, UML models, ODM XMI) is intended to assure users of the ontologies that the ontologies are freely available, for use with attribution, and without warranty. This module metadata is given in the module "About" ontology as described in the sub-clause on the About ontologies.

Issue FIBOFTF2-28: Reordering of specification metadata descriptions to account for About files and additional text.

9.4 Ontology-Level Metadata

Each Foundations ontology has a set of curation and rights metadata which is specified in this sub clause rather than being repeated for each ontology. This information is included regardless of whether the ontology is serialized as RDF/XML OWL, UML/XMI with the ODM profiles for RDF and OWL applied, or as ODM XMI.

³ See http://opensource.org/licenses/mit-license.php

Table 9-4. FIBO Foundations Specification Curation and Rights Metadata

dct:license	http://www.omg.org/techprocess/ab/SpecificationMetadata/MITLicense
sm:responsibleTaskForce	http://fdtf.omg.org/

Finally, each ontology will also include ontology-specific specific metadata, using the OMG Specification Metadata ontology. Again, These details are provided with the individual ontologies in Clause 10.

Issue FIBOFTF2-28: New descriptive material about he About files.

9.5 The 'About' Files

Each FIBO submission is to be accompanied by a set of files containing the metadata for the FIBO Family, the individual FIBO specification and the specifications for each module. This is so that metadata for each of these elements of a FIBO submission do not need to be repeated in each ontology. These are collectively known as "About files"

The About files are:

- About the EDMC-FIBO Family
- About the Specification
- About the specification version
- About each Module

9.5.1 EDM Council FIBO Family About File

This is to be included with each FIBO specification submission. It has the filename AboutTheEDMC-FIBOFamily.rdf and includes the family level metadata described in sub-clause 9.2.

9.5.2 Specification About File

This is unique to each FIBO specification and is named according to the specification 3- or 4-letter abbreviation, for example (for Foundations) AboutFND.rdf

This file includes the specification-level metadata described in sub-clause 9.2.

9.5.3 Specification Version About File

This is unique to each FIBO specification and is named according to the specification 3- or 4-letter abbreviation and its version, for example (for Foundations) AboutFND-1.0.rdf

This file includes the specification version metadata described in sub-clause 9.2.

9.5.4 Module About File

This is unique to each FIBO module and is named according to the module full name, for example (for Foundations): AboutAgreements.rdf

This file includes the module-level metadata described in sub-clause 9.3.

9.63 Ontology Entity-Level Metadata

This sub clause describes the metadata that are applied to each named concept (Class and Property) in the ontologies.

9.63.1 Definitions, Notes, and Labels

Table 9-5. Definitions, Labeling, and Notes

Term Requirement	Term Type	Annotation	Usage Notes				
Definition	Definition	skos:definition	Main formal definition of term. Must always be present				
Change history	hange history Note skos: chang		Notes indicating why something was modified				
General note, editorial comment	Note	skos:editorialNote	The bulk of the "Further Notes" narrative is expressed this way				
Examples	Note	skos:example	Examples				
Explanatory note	v IIDO uti		Notes providing additional explanation about the concept				
Historical note	Note	skos:historyNote	Notes regarding the history of the concept				
Note	Note	skos:note	Used when no specific note annotation is appropriate				
Scope note	Note	skos:scopeNote	Clarifying information about the scope of the term or concept				
Usage note	Note	fibo-utl- av:usageNote	Used to suggest how a particular concept is intended to be used				
Preferred Label	Label	skos:prefLabel	Replaces rdfs:label if there is a preferred label for the concept				
Alternate Label	Label	skos:altLabel	Alternate label additional to prefLabel. Should be used instead of rdfs:label for alternatives				

9.63.2 Synonymous Terms

Synonyms are fundamental to the reporting required for business domain view and review of the ontologies, which, at a basic level, may only require the concept, a label, its formal definition in text form, and any synonyms.

Fundamentally, an ontology, and any extensions derived from it, should contain only a single element defining a given concept, with synonyms captured using the fibo-utl-av:synonym annotation property. Within a given ontology, use of separate classes with the same meaning, together with the OWL construct for class equivalence (equivalentClass) is not considered best practice. Such an approach may be necessary to align or map ontologies to one another, however, where the same concepts exist in different namespaces. fibo-utl-av:abbreviation may be used to specify abbreviations and acronyms associated with concepts as appropriate.

9.63.3 Provenance and Cross-reference Annotation

Where possible, every effort is made in the FIBO ontologies to provide references for the origin of terms and their definitions, including cases where those definitions have been adapted for FIBO usage. While less important for

Foundations, any FIBO ontology that includes terminology from a particular standard, such as FpML, ISO 20022, any regulatory publication, and so forth should note it as the source for a given concept or its definition.

Four annotation properties are provided in the FIBO AnnotationVocabulary to facilitate provenance documentation for the terminology and definitions specified in the standard. These are:

- fibo-utl-av:adaptedFrom used where the text in the skos:definition is adapted from the definition of the term defined in the range of this property (range can be a string, URI, or BibliographicCitation). Note that this initial version of Foundations does not recommend a specific standard for citatations. There are a number of ontologies that might be considered for this purpose, and the OMG Specification Metadata provides a class called BibliographicCitation that can be used as the range of this annotation and can be mapped to the preferred citation definition for a given application, organization, or repository.
- fibo-utl-av:definitionOrigin used where the text in the skos:definition is a direct copy of the definition of the term defined in the range of this property (range can be a string, URI, or BibliographicCitation).
- fibo-utl-av:termOrigin which provides the means to document the source of a term, in a standard, in some other document, or by some organization. The range of this property is the document and / or organization from which the term was derived (range can be a string, URI, or BibliographicCitation).
- fibo-utl-av:nameOrigin which provides the means to document the name of the original term in the standard, other document or organization referenced via the annotation fibo-utl-av:termOrigin

9.63.4 Change Management Annotation

In addition to the version information provided at the specification level for a given FIBO ontology, additional annotations for change management purposes may be appropriate at the concept level. These may include:

- skos:changeNote
- fibo-utl-av:modifiedBy identifying the person and/or organization responsible for the change
- fibo-utl-av:modifiedOn identifying the date and time of the change

10. Model Content Reports

Intended Audience: Business Analysts, other business stakeholders

This clause shows the content of the model from a business perspective. Model content is presented both as diagrams and as tables. Readers do not need to be conversant with the Web Ontology Language or other modeling languages in order to be able to interpret what is presented here. However some familiarity with the "set theoretic" interpretation of the model content is required.

This clause has a sub clause for each ontology that is automatically generated from the ODM representation of that ontology, and is designed to be more human-readable than the raw OWL file.

The following Table 10.1 explains the headings used and what these mean in terms of the semantics of the model elements presented.

Table 10-1. Table Guide

NOTE: Not all of these entries are provided in every sub clause.

Heading	Description
Name	The formal name of the model element. This is in the "CamelCase" format.
Type of Thing	The name of the class of "Thing" or, for properties, the class of thing for which that is a property. Note that properties which are intended to be widely used will state "anything" in this column, meaning that it is intended to be a property of "Thing", the set of which everything is a member.
Property	The name of the property (blank for entries which describe a type of thing).
Definition	The formal written definition of the type of thing or the property.
Synonyms	The or any synonyms which are identified for the concept.
Equivalent To	Identifies a class or property restriction which is the same in meaning
Parent	For types of thing, the type of thing for which it is a sub-type, sharing properties of that thing.

Heading	Description
Mutually Exclusive With	Indicates that a type of thing is mutually exclusive with the other type of thing identified in this column. This means that no individual thing may be a member of both sets.
Related Thing Or Type	For relationship properties, the type of thing in terms of which the property is framed or (in subject-predicate-object terms) the object of the property. For example a property like "has jurisdiction" would be framed in terms of the type of thing, which is a jurisdiction.
	For simple properties, the type of information in terms of which the property is framed (e.g. text, date, yes/no or selection of textual descriptors)
Inverse of Property	Identifies a property which is the opposite or inverse of the one in this line. For example is a customer holds an account, and an account is held by a customer, these properties are the inverse of one another.
Multiples	Indicates where a property may have specific multiples of the item identified as the related thing or simple type. Where properties are reused or refined, this indicates specific limitations on the numbers of the kind of thing identified as the related thing for the reused property.
Concept type	Gives the natural language description of what kind of concept is being reported on in this line of the table, e.g. class (type of thing), Simple Property, Relationship Property and so on.
Explanatory Note	Provides any textual information that has been included about the concept, over and above the formal definition for the concept.
Term Origin	For concepts, which have been included with reference to, some other source (typically an industry standard data model) this column identifies the document, standard or other resource from which the term was derived.
Definition Source	For concepts for which a definition has been taken from some other source this column identifies the document, standard or other resource from which the definition was directly taken.
Adapted From	Where definitions have been taken from other sources but adapted, this column identifies the source of the original definition. This is typically the case when a definition is taken

Heading	Description
	from some technical industry standard, and the description of a data field or message element is re-worded to describe the real world thing to which that element applies.

10.1 Module: Utilities

Table 10-2. Utilities Module Metadata

Metadata Term	Value
sm:moduleName	Utilities
sm:moduleAbbreviation	FIBO-FND-UTL
sm:moduleVersion	1.0
sm:moduleAbstract	Ontologies which provide annotations and business facing datatypes to be used in other ontologies. These ontologies are not expected to be used directly by business stakeholders and are for the definition of material which is used by semantic modelers in Foundations and in other FIBO ontologies.

10.1.1 Ontology: Annotation Vocabulary

This vocabulary provides a set of metadata annotations for use in describing FIBO ontology elements. The annotations extend properties defined in the OMG's Specification Metadata Recommendation, in the Dublin Core Metadata Terms Vocabulary and in the W3C Simple Knowledge Organization System (SKOS) Vocabulary, and have been customized to suit the FIBO specification development process.

Note that any of the original properties provided in Dublin Core and SKOS can be used in addition to the terms provided herein. However, any Dublin Core terms that are not explicitly defined as OWL annotation properties in this ontology or in any of its imports must be so declared in the ontologies that use them.

		context										

10.1.2 Ontology: Business Facing Types

This ontology provides high level definitions for business facing datatypes for use in other FIBO ontology elements. These types are essentially aliases of existing Financial Industry Business Ontology Foundations Bota 2 Final 57

RDF datatypes, and are provided in order to be able to present datatype properties to a business audience with non technical names, for example yes or no in place of boolean and text in place of string. All datatype properties in the FIBO ontologies are framed in terms of these business-facing types and not in terms of the underlying technically-named datatypes.

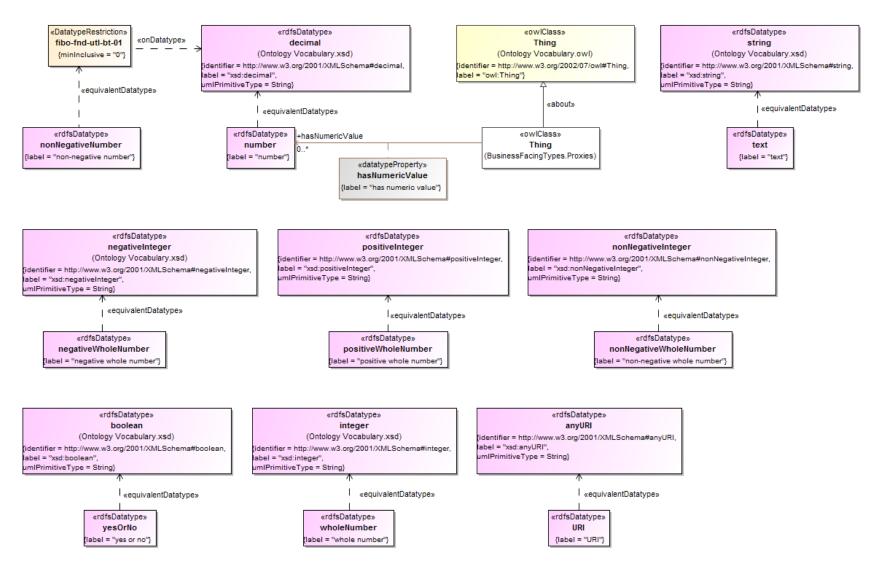

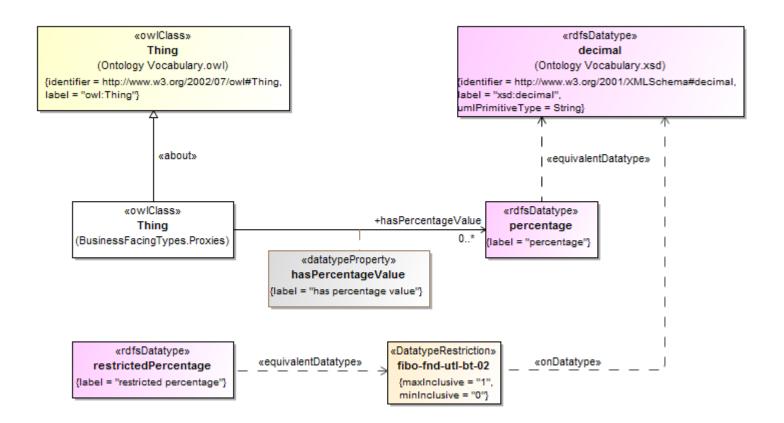

Figure 10.5 General Purpose Business Types

As shown in Figure 10.5, a number of business types are defined for use in other definitions in FIBO. These are provided to facilitate understanding by business subject matter experts, using common language rather than technical nomenclature. Note that a non-negative number is defined using a datatype restriction, fibo-fnd-utl-bt-01, that can be interpreted as saying that a non-negative number is declared to be of type xsd:decimal whose values must be greater than or equal to zero.

Issue FIBOFTF2-11: Update Figure 10.6 with new percentage model

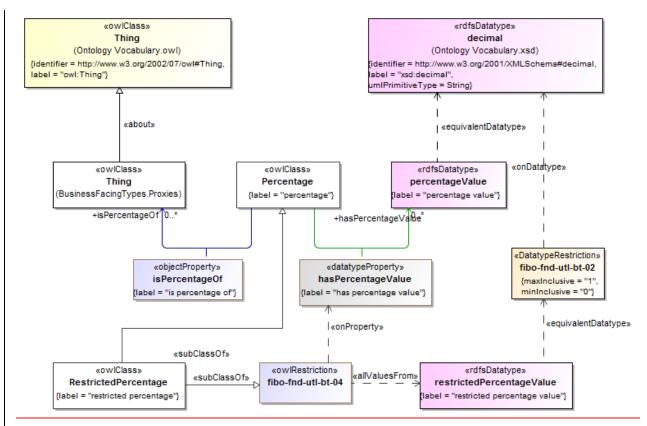

Figure 10.6 Percentage Definitions

Figure 10.6 depicts the definition of two datatypes that can be used in other FIBO definitions for the purposes of specifying percentage values. These include (1) percentage, which is declared as an xsd:decimal (and can be negative), and (2) restricted percentage, which must be an xsd:decimal whose values are restricted (in fibo-fnd-utl-bt-02) to range from zero to one.

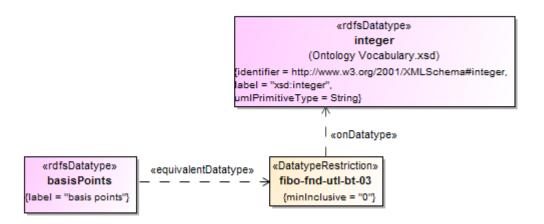

Figure 10.7 Basis Points Definition

Figure 10.7 declares the definition of basis points to be an xsd:integer whose values must be greater than or equal to zero (fibo-fnd-utl-bt-03).

Table 10-6. Business Facing Types **Details Definitions**

Issue FIBOFTF2-11: New names and definitions for percentage related datatypes.

Also renamed table because a further table is added in the usual 'details' format

Datatype	Definition	Equivalent Datatype	Concept Type	Definition Source
basisPoints	A basis point is a unit equal to one hundredth of a percentage point, or one part per ten thousand, 1/10000.	fibo-fnd-utl-bt-03	Datatype	
negativeWholeNumber		negativeInteger	Datatype	
nonNegativeNumber		fibo-fnd-utl-bt-01	Datatype	
nonNegativeWholeNumber		nonNegativeInteger	Datatype	
number	A number is a mathematical object used to count, label, and measure.	decimal	Datatype	
percentage Value	the value of a percentage expressed as a number or ratio as a fraction of 100 In mathematics, a percentage is a number or ratio as a fraction of 100. It is often denoted using the percent sign, %, or the abbreviation, pct.	decimal	Datatype	
positiveWholeNumber		positiveInteger	Datatype	
restrictedPercentage <u>Value</u>	A type defining a percentage specified as decimal from 0 to 1. A percentage of 5% would be represented as 0.05. The maximum value is 100%, i.e., 1.	fibo-fnd-utl-bt-02	Datatype	
text	the contents of an ordinary sequential file readable as textual material without much processing	String	Datatype	

Datatype	Definition	Equivalent Datatype	Concept Type	Definition Source
URI	a uniform resource identifier (URI) is a string of characters used to identify a name or a web resource.	anyURI	Datatype	
wholeNumber		integer		
yesOrNo	something which has two states, interpreted as Yes and No in the context in which this is used	boolean

10.3 Module: Goals and Objectives

Table 10-130. Goals and Objectives Module Metadata

Metadata Term	Value
sm:moduleName	Goals and Objectives
sm:moduleAbbreviation	FIBO-FND-GAO
sm:moduleVersion	1.0
sm:moduleAbstract	This module includes ontologies for goals and objectives which may be pursued by people or organizations. Goals form the basis for the definition of an organization, and objectives and related concepts are required for describing business plans.

10.3.1 Ontology: Goals

This ontology defines the concept of a goal, for use in other FIBO ontology elements. Goal is defined in general terms and forms one of the basic properties of organizations.

Goal	goal		a goal is a desired result that a person, organization or system envisions or plans, or to which it com- mits, in order to achieve a desired state						Class		Many people endeavor to reach goals within a finite time by setting dead- lines.	http://en.wikipedia.or g/wiki/Goal

10.3.2 Ontology: Objectives

This ontology defines the concept of an objective, for use in other FIBO ontology elements. Objectives are defined as being distinct from goals, in that they constitute time limited and measurable targets which some entity may seek to attain in pursuit of its goals.

Objective	objective		a statement of a quantitative, measurable result that a person, organization, or system seeks to attain in order to achieve its goals						Class		This provides an attainable, time-limited, and measurable result that defines strategy and that a person, organization, or system seeks to meet in order to achieve its goals.	Forrester Research

10.4 Module: Parties

Table 10-185. Parties Module Metadata

Metadata Term	Value
sm:moduleName	Parties
sm:moduleAbbreviation	FIBO-FND-PTY
sm:moduleVersion	1.0
sm:moduleAbstract	This module includes ontologies defining concepts that are highly contextual in nature, such as the meaning of a party in a role, an agent playing a role, and so on. Also covers independent roles themselves.
	The definitions for agents and parties in roles provide general, reusable patterns for talking about agents performing roles in specific contexts. For example the same person in the context of aviation could be a pilot, and in the context of family could be a mother. These pattern will be refined in other FIBO ontologies to define concepts such as issuer, counterparty, underwriter, etc.

10.4.1 Ontology: Parties

This ontology defines the high-level concepts of parties in roles, for use in other FIBO ontology elements. The concept of a party in a role describes some entity defined specifically in terms of some role which it performs in some formal contractual or transactional relationship. The ontology includes one or more basic party in role concepts. The ontology also includes one or more logical combinations of types of autonomous entity which may perform some of the party roles defined elsewhere in this ontology, such as the role of ownership.

10.4.2 Ontology: Roles

This ontology defines some high-level concepts of roles for use in other FIBO ontology elements. These concepts include the basic property whereby something has some role, along with the high-level concept of an agent in a role. The agent in role concept provides the basis for party in role concepts in the PartyRoles ontology and is framed as some entity defined specifically in respect to some role which it performs in some context.

10.6 Module: Agents and People

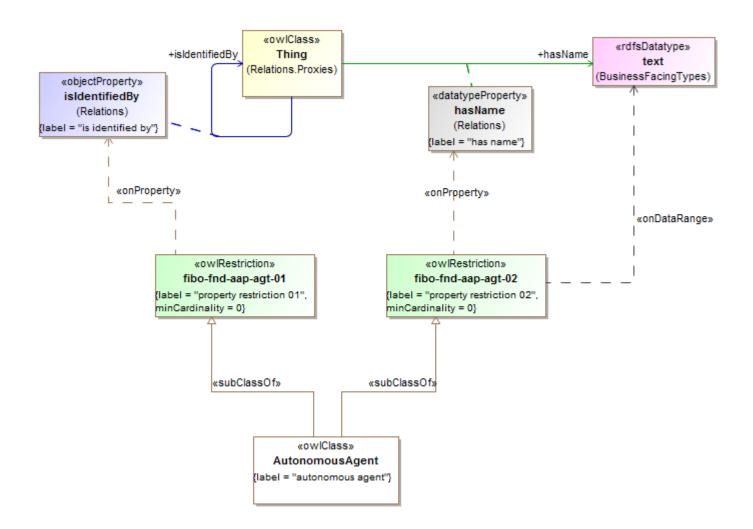

Table 10-3225. Agents and People Module Metadata

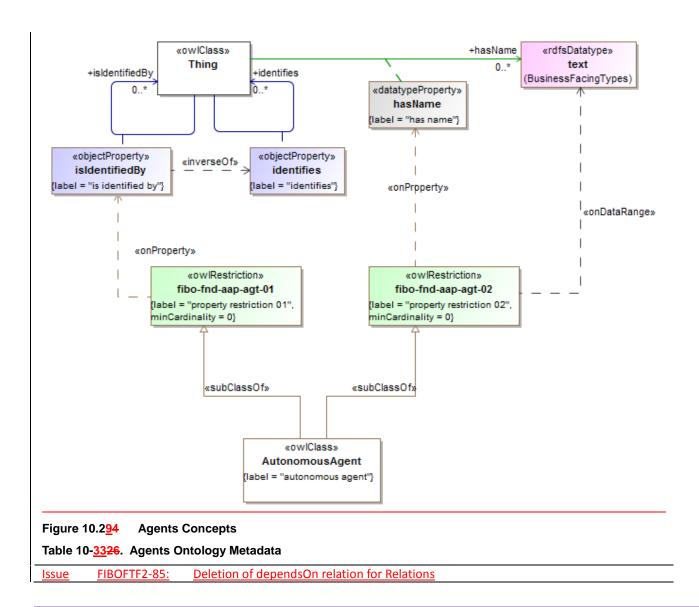

Metadata Term	Value
sm:moduleName	Agents and People
sm:moduleAbbreviation	FIBO-FND-AAP
sm:moduleVersion	1.0
sm:moduleAbstract	This module contains ontologies of concepts relating to types of autonomous entity, that is things in the world which are able to determine their own behavior. Includes ontologies for people and for autononomous entities in general.

10.6.1 Ontology: Agents

This ontology defines the concept of autonomous agent for use in other FIBO ontology elements. As defined here, autonomous agent corresponds to what is often referred to as "agent" in software and other systems. It is defined as any entity which is able to act on its own part, and embraces all such things, including people, animals, software agents organizations and all forms of legal persons, although not all of these concepts are elaborated in FIBO as not all are relevant to financial services.

10.6.2 Ontology: People

This ontology defines concepts for people and human related terms, for use in other FIBO ontology elements. People as defined here are human persons only. This ontology sets out a number of basic properties that are held by people or are definitive of a small number of specific types of people such as minors or adults. Primary use cases for determining the set of personal information definitions included are the common elements required to (1) open a bank account, (2) identify a sophisticated investor, and (3) establish foreign account ownership for money laundering purposes.

											benefits, health care,	
											and other govern-	
											mentally-related	
											functions. The num-	
											ber will appear on an	
											identity document	
											issued by a country.	
											The ways in which	
											such a system is	
											implemented are	
											dependent on the	
											country, but in most	
											cases, a citizen is	
											issued an identifica-	
											tion number at birth	
											or when they reach a	
											legal age (typically	
											the age of 18). Non-	
											citizens may be is-	
											sued such numbers	
											when they enter the	
											country, or when	
											granted a temporary	
											or permanent resi- dence permit. Many	
											countries issued such	
											numbers ostensibly	
											for a singular pur-	
											pose, but over time,	
											they become a de	
											facto national identi-	
											fication number. For	
											example, the United	
											States originally	
											developed its Social	
											Security number	
											system as a means of	
											disbursing Social	
											Security benefits.	
											However, due to	
											function creep, the	
											number has become	
											utilized for other	
											purposes to the point	
											where it is almost

											include undeveloped land, houses, condomini- ums, town- homes, office build- ings, retail store build- ings and factories.	
Physical- Location	physical location		A location in physical space		location				Class			
Location	location		Anything that can be defined as the answer to a question of the form, Where is?						Class			

10.7.2 Ontology: Countries

This ontology provides a very high level definition of country related concepts, essentially a placeholder for use in mapping countries and intra-country concepts to the appropriate regional standards or to some as yet undefined global address ontology, for use in other FIBO ontology elements. A minimal set of geopolitical and geophysical terms are included as required for financial risk management and other application use cases, and these are all to be considered as placeholders for suitable standard ontologies for these concepts as these become available. These terms may also be mapped to controlled vocabulary standards such as ISO 3166.

10.8 Module: Organizations

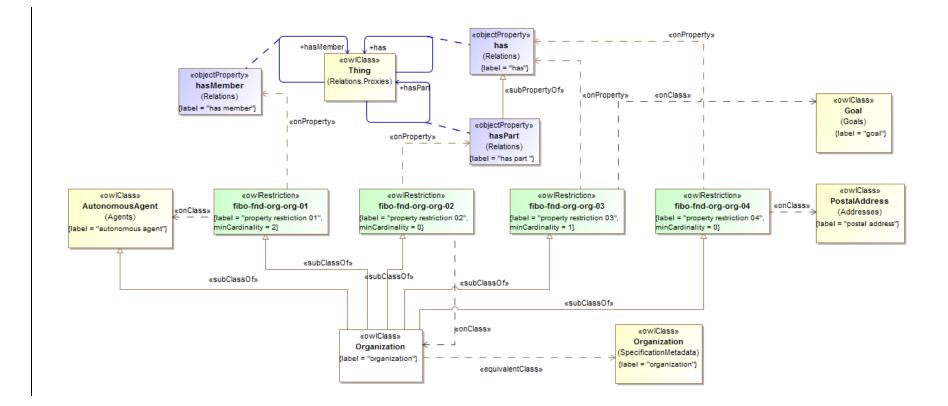

Table 10-4836. Organizations Module Metadata

Metadata Term	Value
sm:moduleName	Organizations
sm:moduleAbbreviation	FIBO-FND-ORG
sm:moduleVersion	1.0
sm:moduleAbstract	This module includes several ontologies defining organizations, features of an organization and different types of organization. These include formal versus informal organizations, legitimate and illicit organizations and so on. They are purposefully underspecified to facilitate mapping to specific organization ontologies, such as the emerging W3C organization and formal organization ontologies, organization from a BMM or BPMN perspective, organization from a records management (RMS) perspective, and so forth.

10.8.1 Ontology: Organizations

This ontology defines high-level concepts for organizations and related terms, for use in other FIBO ontology elements. It is purposefully underspecified to facilitate mapping to specific organization ontologies, such as the emerging W3C organization ontology, organization from a BMM or BPMN perspective, organization from a records management (RMS) perspective, and so forth.

Issue	FIBOFTF2-70:	Remove equivalence relation to external organization ontology and class.
Issue	FIBOFTF2-4:	Change to restriction style (from cardinality to allValuesFrom) to accommodate proper-
		ty characteristics

10.8.2 Ontology: Formal Organizations

This ontology defines the high level concept of formal organization for use in other FIBO ontology elements. It is purposefully underspecified to facilitate mapping to other formal organization ontologies, such as the emerging W3C formal organization ontology, or others defined for specific business and financial services standards. The concepts in this ontology extend those in the Organizations ontology.

FormalOr- ganization	formal organization		An Organization that is recognized in some legal jurisdiction, with associated rights and responsibilities. Examples include a Corporation, Charity, Government or Church.		organization	informal organization			Class	W3C Definition - An Organization which is recog- nized in the world at large, in particular in legal jurisdictions, with associated rights and re- sponsibilities. Examples include a Corporation, Charity, Govern- ment or Church.		Adapted from W3C Organiza- tion On- tology
isDomiciledIn	formal or- ganization	is domiciled in	the country in which the formal organization is officially domiciled				country		Relation- ship Property		This would normally be the country corresponding to the jurisdiction in which the formal organization is constituted or incorporated. For some primarily federal countries, the domicile is the country that makes up the federation while the jurisdiction under which the entity is registered (if it is a registered entity) would be that of some state in that federation.	

10.8.3 Ontology: Legitimate Organizations

This ontology defines the concepts of legitimate and illicit organizations for use in other FIBO ontology elements. These distinctions are provided in order to 200

facilitate modeling of concepts relevant to money laundering. Legitimate organizations such as clubs are defined. These, along with the distinctions of formal versus informal organizations, provide the universe of possible kinds of organizations which may perform specific roles such as holding shares, having control of assets of companies and so on.

Legiti- mateOrgani- zation	legitimate organiza-tion		An organization that exists to serve some lawful purpose		organiza- tion	illegal organ- ization			Class			
IllegalOrgani- zation	illegal or- ganization		A kind of organization which has been set up specifically to perform illegal acts or has become such		organiza- tion	legitimate organization			Class		This is not to do with performing illicit acts. We can narrow down on a definition for Illicit Organization one which has been set up specifically to perform illicit acts or has become such. This relates to the purpose of the organization, and the purposes of the entities which control that entity. And the acts which the entity may perform. (definition adopted from the above note, with Illicit changed to Illegal for clarity). Typically, a money laundering entity may perform (will perform) legal acts and is explicitly set up for such, but will also perform illicit acts. The definition of illicit is framed entirely with respect to law and not morality.	
IllegalCartel	illegal car- tel		A collection of companies that come together to manipulate the market in some way, e.g. price fixing		property restriction 01 illegal or- ganization				Class			
fibo-fnd-org- lg-01	property restriction 01		Set of things with property "has member" only "for- mal organization"						Property Re- striction

10.9 Module: Agreements

Table 10-5543. Agreements Module Metadata

Metadata Term	Value
sm:moduleName	Agreements
sm:moduleAbbreviation	FIBO-FND-AGR
sm:moduleVersion	1.0
sm:moduleAbstract	This module includes ontologies describing agreements between parties and contracts that formalize those agreements. These cover written and verbal contracts, including contracts which may be transferred from one party to another. The latter form the basis for financial securities contracts. The Contracts ontology also describes fundamental properties of contracts such as contractual terms, contract parties and so on, many of which form the basis for more specialized financial industry concepts such as interest payment terms, bond issuers and so on.

10.9.1 Ontology: Agreements

This ontology defines concepts for agreements, for use in other ontology elements. Agreements as defined here are the actual agreements between parties, and this ontology is intended to be referred to in conjunction with the contracts ontology which defines the actual contracts which formalize such agreements. The concepts of agreement and contract are intended to be kept distinct in the FIBO ontologies, that is neither is intended to be regarded as a sub type of the other.

Issue	FIBOFTF2-16:	Changes in Agreements to support unilateral agreements; unilateral commitments;
	FIBOFTF2-55:	Changes to Contracts in line with SME review

10.9.2 Ontology: Contracts

This ontology defines concepts relating to contracts, for use in other FIBO ontology elements. These include written contracts which are the concrete evidence of agreements between parties, along with verbal contracts. Contracts are further broken down into bilateral and transferable contracts, the latter being the basis for most financial instruments. Properties of contracts are also defined, in particular contractual terms and contract parties. These concepts all form the basis of concepts in the financial services industry, for example interest payment terms are a kind of contract terms set, and security holders are a kind of contract counterparty.

sm:moduleName	Law

Metadata Term	Value
sm:moduleAbbreviation	FIBO-FND-LAW
sm:moduleVersion	1.0
sm:moduleAbstract	This module includes several ontologies defining legal concepts, including constitutions, laws and jurisdictions. It also includes the definition of legal capacities such as signatory capacity, contractual capability and the like.

10.10.1 Ontology: Legal Core

This ontology defines high-level legal concepts for use in other FIBO ontology elements. These concepts include law and constitution, both of which are framed at a more abstract level than national or state laws and constitutions, so that law forms the basis both for statutes and for company by-laws, and constitution forms the basis both for national or state constitutions and for instruments which are constitutive of incorporated legal entities. This ontology also defines some of the variants of these such as governmental constitutions and ordinances. Other types of law are provided in the Jurisdictions ontology as extensions of concepts in this ontology. Court of Law is also defined here.

10.10.2 Ontology: Jurisdiction

This ontology defines high level concepts relating to jurisdictions for use in other FIBO ontology elements. This includes a general definition of jurisdiction along with some basic types of jurisdiction, along with the factors which distinguish one type of jurisdiction from another. This ontology also defines basic types of legal system, and extends the basic concept of law which is in the LegalCore ontology.

10.10.3 Ontology: Legal Capacity

This ontology defines high-level legal concepts, especially those related to legal responsibilities, for use in other FIBO ontology elements. The ontology defines things which are conferred upon some entity by some legal instrument, and elaborates this into a number of specific capacities, responsibilities and powers, each of which forms the basis for many of the concepts used elsewhere in FIBO in defining legal personhood, executive powers and the like.

fibo-fnd- acc-aeq-01	property restriction 01		Set of things that must have property "repre- sents an interest in" exactly 1 taken from "formal organization"						Property Restriction			
CapitalSur- plus	capital surplus		Capital surplus is that amount which a firm raises in excess of the par value (nominal value) of the shares (common stock).		equity				Class		Capital surplus is a term that fre- quently appears as a balance sheet item as a compo- nent of sharehold- ers equity.	http://en.wi kipe- dia.org/wiki /Additional _paid_in_ca pital
Capital	capital		financial capital, which represents obligations, and is liquidated as money for trade, and owned by legal entities		property restriction 03				Class		Financial capital is in the form of capital assets, traded in financial markets. Its market value is not based on the historical accumulation of money invested but on the perception by the market of its expected revenues and of the risk entailed.	http://en.wi kipe- dia.org/wiki /Capital_(ec onomics)
fibo-fnd- acc-aeq-03	property restriction 03		Set of things with prop- erty "takes form" only "money amount"						Property Restriction			
<u>takesForm</u>		takes form	the form taken by some amount of money de- fined according to its purpose, such as capital or equity				money amount		Relationship Property			

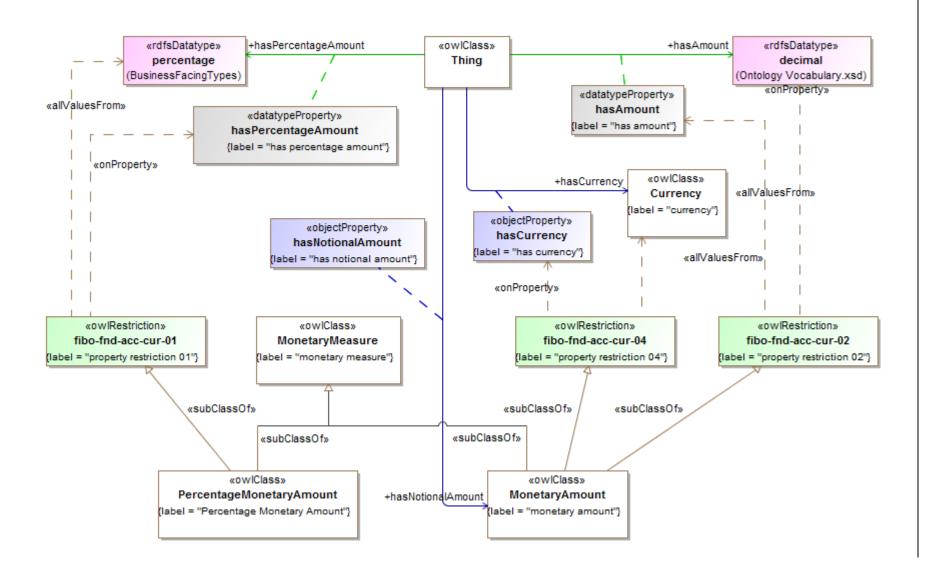

10.12.2 Ontology: Currency Amount

This ontology defines monetary amount related concepts for use in defining other FIBO ontology elements. There are two distinct kinds of concepts that correspond to money and amounts: a concrete, actual amount of money, and the monetary measure of something denominated in some currency. These are dimensionally the same but whereas "money amount" is defined as an amount of money, "monetary amount" is an abstract monetary measure. This ontology also defines related terms such as currency.

Issue FIBOFTF2-11: Changes to use new percentage model

Add new Dates and Times module containing three new ontologies. Issue FIBOFTF2-22:

10.13 **Module: Dates and Times**

Table 10-79. Dates and Times Module Metadata

Metadata Term	<u>Value</u>
sm:moduleName	Dates and Times
sm:moduleAbbreviation	<u>fibo-fnd-dt</u>
sm:moduleVersion	1.0
sm:moduleAbstract	This module includes ontologies describing date and time concepts which are of specific reference in financial services. These cover foundational date

and time concepts in a form usable for financial subject matter ontologies, including occurrences and conventions for business days and the like.

The business day convention concepts are to be further extended in specialized ontologies for securities and derivatives, building on the ontologies in this module.

10.13.1 Ontology: FinancialDates

This ontology provides definitions of date and schedule concepts for use in other FIBO ontologies.

Cass	Duration	[duration]		An amount of time.	fibo-fnd- dt-fd-11								
<u>C</u> ass	Regular- Schedule	[regular schedule]		A RegularSchedule is a Schedule that recurs regularly.	fibo-fnd- dt-fd-21					The BusinessDates ontology extends 'RegularSchedule' with an optional BusinessDa- yAdjustment that specifies what should happen if a scheduled date falls on a weekend or a holiday.	A Regular- Schedule is a Schedule defined as a set of Dates that start on a recurrence start date and repeat after each recur- rence interval. The size of this set is defined by a count. The "initial		
											ScheduleStub" associated with a Regu- larSchedule identifies any special treat- ment applied before the recurrence start date. Simiilarly, a

Annex A: Machine Readable Files Part of This Specification

(normative)

The FIBO ontologies are delivered as (1) RDF/XML serialized OWL (normative and definitive), (2) UML XMI, serialized from UML with the ODM profiles for RDF and OWL applied (normative), (3) ODM XMI, serialized based on the ODM MOF metamodels for RDF and OWL (normative), and (4) Visual Ontology Modeler (VOM) model files, based on the VOM plug-in to MagicDraw (informative). If there are differences between the OWL files, ODM XMI, and UML XMI, the OWL files take precedence, followed by the UML XMI, and finally the ODM XMI.

Regardless of their form, each of the ontologies included in Foundations makes normative reference to the DCMI Dublin Core Metadata Terms⁴, W3C Simple Knowledge Organization System (SKOS) Recommendation⁵, and the OMG Architecture Board's Specification Metadata Recommendation⁶, which are not part of this specification.

The individual RDF/XML files are organized by module (directory), and within a given module, alphabetically by name, as shown in the URI structure for each individual OWL file. These files are UTF-8 conformant XML Schema files that are also OWL 2 compliant, and may be examined using any text editor, XML editor, or RDF or OWL editor. They have been verified for syntactic correctness via the W3C RDF Validator and University of Manchester OWL 2 Validator. They have also been checked for logical consistency using the Pellet OWL 2 reasoner from Clark & Parsia as well as the HermiT OWL 2 reasoner from Oxford University. It is anticipated that the OWL ontologies will be dereference-able, together with technical documentation (HTML) from the OMG site once the specification is adopted.

Note that the ontologies use features of the OWL 2 language and other ODM revisions that will not be available in the Ontology Definition Metamodel (ODM) until the ODM 1.1 specification is published. The ODM RTF has published a convenience document, available to OMG members, that incorporates specification changes required for FIBO that have already been resolved by the working group, and which we anticipate will be available later this year once the report and related specification is published.

Annex B: Shared Semantics Treatments

(normative)

B.1 Introduction

Intended Audiences: Semantic Modelers; Technical architects

The model content is grounded in terms which come from outside the realm of business entities of financial services. These are maintained in the Foundations ontology. Wherever possible, terms in this annex are cross referenced to terms set out by suitable standards bodies and academic bodies, so that the meanings of these terms are grounded in a broader community of semantics modeling.

Some of these external standards are in the form of formal ontologies, modeled typically but not necessarily in the Web Ontology Language (OWL) and in any case grounded in formal first order logic. In addition, some terms are derived from models which are not formally grounded in first order logic but which in some way or another are identified as meaningful concepts, either by explicit mark-up of the model content, by some separate theory of meaning, or by some statement at the level of the model identifying it as a semantic model. Such models are typically in the Unified Modeling Language (UML) or some other formalism such as that of the eXtensible Business Reporting Language (XBRL).

Some of the models are only referred to in part, for example because the scope of the standard, as identified by its business requirement, is very different to the scope of the concepts in the Foundations ontologies, or because the ontology contains formal axioms or facts which are at odds with Foundations.

This annex describes the range of treatments by which such external standards are cross referenced in the Foundations ontologies. A number of such treatments have been identified, depending on the nature of the standard or vocabulary referred to in FIBO Foundations, the language in which it is framed or the extent to which we are confident of making direct formal reference to it. For example, for some ontologies we wish to make direct, explicit reference, whereas for others we may have less visibility or confidence in the maintenance arrangements of that model's content and so have elected to create a local 'snapshot' of that ontology with its own namespace.

B.2 Shared Semantics Treatments

Case 1: Complete, stable OWL Ontologies

Treatment: If an ODM representation does not already exist as part of the standard, create a surrogate of the ontology using ODM.

Because this is in ODM, it shall have the actual URIs of the external standard. The material in FIBO represents a direct use of that ontology with its original namespace.

Case 2: Ontology Snapshot

If the external ontology is in OWL but we want to make a snapshot of it at a point in time

Treatment:

- Create clone copy of the ontology in our repository
- Allocate a URI which identifies this as a clone (to include the elements of the original URI plus "/fiboclone/")
- Use OWL equivalentClass, to point from an element in the FIBO clone to the corresponding element in that ontology.

When to use snapshot

This is used when for any reason we don't want to reference changes to the external ontology.

Case 3: Partial Snapshot

This treatment is for when the external ontology has a broader or different business requirement and range of concepts, such that we may not wish to refer to or replicate them all.

Treatment: Create a clone of only those the parts of the ontology we wish to refer to.

Otherwise the treatment is the same as for Case 2, except that in place of the URI fragment "/fiboclone", the fragment "/fibopartialclone" should be used.

Annex C: Logical versus Conceptual Models comparison

(informative)

Intended Audiences: Technology Management

C.1 Comparison Table

The principal differences between a logical data model and a semantic model are shown in Table C1.1.

Table C1.1 Model Comparisons

Logical Data Model	Semantic Model
Represents elements in a database design	Should not include design information but is a model of business concepts
Represents data model design components (Classes in OO design; tables in relational database design)	Represents "Things" using set theory concepts
Combines common data structures for reuse and efficiency	No efficiency considerations because it is not a design; reiterates concepts as they apply
Single inheritance hierarchy	Multiple inheritance
May define a number of optional properties of a class, such that the application developer would know whether these apply or not	Defines what facts are applicable to a given type of thing.
Uses enumerations to quality classes	Enumerates classes ("Things")
Closed World Assumption (CWA)	Open World Assumption (OWA)

These are explained further in the sub clauses which follow.

C.2 Detailed Models Comparison

Design Elements versus Business Concepts

A logical data model represents the design of some data structure such as a database or a message design. This differs from a physical data model in that it is not specific to any one implementation or platform. That is, a logical data model is a kind of "Platform Independent Model" or PIM, as distinct from a "Platform Specific Model" or PSM.

While a logical data model is not specific to any one physical implementation, it does represent some design. That is, the logical data model, like any logical design, represents the results of some design effort by some designer.

A semantic model does not represent any design of any solution, but explicitly represents facts about the problem domain.

If a designer sets out to design something, there should normally be something that they are working from. In the design of software, designers work from formal business requirements statements, such as "Use Case" models or a requirements specification document. For data, the equivalent is a semantic model. That is to say, a designer of a data model should be expected to work from some source of knowledge of the items which are to be catered for in the database or messages for which they are carrying out the design.

Components that are Represented (Classes, Tables or Things)

In order to create a model which represents the logical design of some database or message scheme, the modeler will create a model which represents components of that design. For example, in a relational database they will create a model of database tables, along with relationships between those tables, public and private keys and so on. A logical representation of the design is therefore a representation of database constructs, namely tables, relationships, keys and so forth. The logical data model design is therefore couched in a notation which has formal representations of those elements. This may take the form of an Entity Relationship Model (ERM) or an object oriented model in the form of a Class Model in the UML design notation.

Depending on the model notation chosen by the developer therefore, the model may be an ERM model of data entities and relationships, or a UML class model of classes, associations, composition relationships and so on. These are the items to which elements of the model refer.

By contrast, a semantic model does not represent a logical design, and the things in the semantic model represent instead the real world entities in the business domain itself.

For example, a logical data model for securities may contain a representation of data tables for data about shares, bonds and so on, whereas a semantic model of the securities domain will contain representations of shares and bonds themselves, as kinds of "Thing".

The relationship between a semantic model element and the things it represents is made explicit in the Semantic Web "Web Ontology Language" or OWL notation. In an OWL model, every kind of "Thing" in the model (also known as "Classes") is a set theory construct which defines membership of the set in terms of the properties of its members. All classes in an OWL ontology model are sub-classes of a class known as the "Universal" set, commonly labeled as "Thing". This is the set of which everything is a member. In this way it is made explicit that everything in the model is some thing.

Reuse

It is sensible when carrying out data model design, to identify similar sets of terms and combine these into reusable sets. A semantic model may end up combining common concepts if the concept can be described as a more general, more abstract variant of the kind of thing. However, this is not a requirement for model design - things may be combined according to similarity in the data structures without reference to their meaning.

This is really another aspect of the basic fact that, since a semantic model is not a design, it has no design constraints (note this may not the case for an individual semantic technology application, where constraints are rightly applied but are very different to those for relational database or message design).

Single versus Multiple Inheritance

A limitation of some (though not all) relational design environments and notations is that the classes would be arranged in a hierarchy of classes. These would be in a single inheritance "tree" i.e. each class has only one parent class of which it is a specialization (ignoring polymorphism for now).

Semantic models more closely reflect the real world dispensation of taxonomies of kinds of thing, namely that a set of classes may defined according to more than one property. For example, a whale is both a marine animal and a mammal according to two different kinds of classification hierarchy, and an individual whale, being a member of the class of things which are a whale, is classified as both kinds of thing.

This is particularly valuable in modeling of kinds of security for different applications. For example risk management and securities trading performance analysis have different requirements, based on asset types, cash flow behaviors and so on. One application would need to classify things according to one set of requirements. Regulators have different requirements to traders, and even different regulators or different areas of regulatory analysis and systemic risk analysis may dictate different ways in which the universe of instruments may be "sliced" for analysis.

Optionality

In standards, particularly message standards, it is good practice to have a number of properties that may or may not apply to a given category of data element (for example, for a data element for a debt security), and make all of these optional. This is practical: for any debt instrument, not all the properties necessarily apply, but someone wanting to send a message

from one point to another will be able to populate the message with those properties that exist for that security.

This, by definition, does not represent the knowledge that business practitioners may have about what facts necessarily must apply for a given instrument of a given type. In order to provide a message which is complete and correct, the sending party needs to apply knowledge from outside the model, about what facts necessarily apply to a given instrument. This intelligence would typically need to be built into the application that builds the message which is sent according to that schema. The knowledge is not represented in the schema.

At base this is simply another way of saying that the logical design of the message is not a representation of the knowledge about the instrument. Needless to say, this is not a criticism of such a message, it is simply a statement of why the message schema is not a record of the knowledge about the instruments.

Enumerations

A valid and good design approach to different kinds of thing is to provide a single data element which is an enumeration, containing entries for each of a number of entries that distinguish these things.

In a semantic model, each thing in the enumeration is a separate class of "Thing". The presence of enumerations in a model indicates that this is a logical model.

Note that for simplicity is it sometimes the practice to provide an enumeration (of textual strings, or 'literals') in a semantic model. However this is usually a pointer to the need to develop the semantics of the model further.

Open versus Closed World Assumption

FIBO specifications are expressed in OWL, which uses the Open World Assumption.

- Open World Assumption: Absence of evidence is not evidence of absence
- Closed World Assumption: Absence of evidence is evidence of absence

What this means in practice is that facts can be asserted about a thing in a semantic model without consideration to whether these facts are represented by actual data. For example, a fact about any event is that it has a cause, however causes of events need not be known or represented.

On a more detailed level, a semantic model can describe and represent facts about things without those facts being represented as data. Very often the facts, which define the nature of a thing, may not correspond directly to data. For example, many financial instrument types are defined in terms of the legal rights and obligations that they represent to one or other party to the contract. These rights and obligations may correspond indirectly to data elements, but the legal facts themselves may be more abstract, i.e. a fact stated in terms of "has right to" or "commits to" may refer to the abstract concept of a right, while the data may contain details of those rights and obligations, which may be regarded as a sort of signature revealing the existence of those rights and obligations.

This would be true of anything which is defined and classified according to facts which are themselves abstract. This would include most legal concepts.

C.3 Model Partitioning

The FIBO Foundations concepts are partitioned into several non-mutually exclusive categories, in the sense in which the term "partition" is used in the semantic modeling community. These are:

- Independent, Relative and Mediating things
- Concrete and Abstract things
- Continuant and Occurrent things.

Each partition is represented as a class of OWL Thing and as a sub-type of the OWL Thing class, without additional archetype indications.

Terms defined in the model in this specification, and any terms defined in future additions to this specification or in local ontologies derived by extension of this specification, may not have a direct parent class of 'OWL Thing'. All classes of

thing in the model described in this specification are given a parent which is either an archetype class of Thing or has an archetype as an ancestor, and all archetypes are given a parent from each of the three partitions listed above, with the exception of temporal terms which exist in a separate partition to the above.

Users of parts of this model may optionally ignore the above partitions in order to dispose model content under separate partitions of their own.

C.3.1 Independent, Relative and Mediating Things

This set of partitions provides a division into the model according to categories which have been arrived at through a considerable body of philosophical literature, notably that of C. S. Peirce. This partitioning relies on the claim in that literature that all things which can be named and classified fall into one and only one of these categories. This principle is reflected in the model described in this specification.

An independent thing is something which is defined in its own right and without reference to any context. For example, a business entity is an independent thing.

A relative thing is something the definition and meaning of which is specific to some specific context. That which is defined in that context is itself identified as some independent thing, or in some cases some other kind of relative thing, which stands in the role or relationship defined as the relative thing. For example a party to a contract is a relative thing, being itself some independent thing, in this case some business entity.

A mediating thing is the context in which some thing is defined as being some relative thing. For example, the context of contractual relationships, or of the context in which some specific kind of contract is entered into, is the mediating thing in which the business entity is identified as being some contract party. The term 'Mediating Thing' is synonymous with 'context' in the broadest sense of that term.

Relative things always have a relationship of 'identity' with some thing which may stand in the role identified by the relative thing. This is usually but not always some independent thing. In some cases the identity relationship may refer to some other relative thing, for example a securities issuer may be a 'Special Purpose Vehicle' which itself is defined as a kind of relative entity, the identity of which may be a company incorporated by the issue of shares, a limited liability partnership or some other form of legal entity. For this reason, while relative things should normally have an identity relationship to some independent thing, the most general application of this relationship is to the universal class 'Thing'.

C.3.2 Concrete and Abstract Things

This partition simply identifies whether something is a concrete item with weight and mass, or an abstract construct. Many of the concepts formally identified in the financial services industry are by their nature abstract.

Archetypes may only be identified as concrete or abstract if this is necessarily the case for all things of that archetype.

Note that things which have legal standing and which may be either provided on paper or in a dematerialized form are identified in this model as concrete. The intention of the Abstract partition is to define things which by their very nature are abstractions, such as goals.

One important class of abstract things is those things that are made up of information. According to the modeling principals, only things which are real may be represented in this model. This necessarily excludes things like database keys and locally defined identifiers. A common sense test needs to be applied to any kind of information before it is considered to be real and therefore able to be modeled here. Public information constructs such as security identifiers, business entity identifiers, credit ratings and the like pass this test because they are published by some party. In addition, documents and messages and the like which are passed between entities or parties in the course of carrying out some business process are equally real even though they are not published. The test for their reality is passed because information constructs such as documents have some real business, legal or financial import, that is some impact on something which is itself modeled as being part of the real world and not part of the technical design of some data or application.

C.3.3 Continuant and Occurrent Things

This partition segregates things which by their nature have some existence of a period of time, with a beginning and an end to their existence, and things which by their nature occur at a point in time. The precise timescales on which a thing may be said to occur or to have an ongoing existence is itself dependent on the domain being modeled, in this case all concepts relating to business entities and more broadly to the carrying out of business activities in the human world. So for example a human being would be considered on an astronomical scale as an occurrent thing, the difference in granularity in the time scales being determined according to the context in which the ontology is to be used. More precisely, a human being could still be considered as a Continuant Thing, with a human life being the corresponding Occurrent Thing, so in many cases it is reasonable to try to frame definitions of things which are clearly either continuant or occurrent.

For the avoidance of doubt, the partitioning of continuant from occurrent things is not formally represented by any axioms, and is definitional only. This means that terms in this model may be cross referenced to terms in models which use different formal ways of distinguishing continuant from occurrent things, for example what are called four dimensional, three dimensional, and similar modeling arrangements. The partitioning given in the model described in this specification contains no such assertions and is provided to enable the problem domain to be partitioned according to the basic nature of what is defined. This enables the model to contain concepts to do with events, processes, states and the like, though these are not utilized in the business entities semantic model.

Annex D: How to extend FIBO ontologies

(informative)

Intended Audiences: The intended audience for this Annex is semantic modelers, who are expected to have some familiarity with the basic principles of semantic modeling but not necessarily with the principles specific to FIBO. Basic OWL principles are also reiterated here. This annex is not intended for purely business audiences or purely technical audiences.

This Annex should be read in conjunction with the clause on Conformance (2).

D.1 Terminology used in this Annex

There are several sets of terminology in use throughout this specification, and the meanings of some terms (such as 'thing') may be different in different specialized usages. Here the intended sense of these words, unless otherwise stated, is the sense used for business communication of the ontology content, and not the sense used in technical modeling or conventional Semantic Web terminology. If a formal definition of a term is not given or referred to via the "Definitions" clause of this specification (4), the normal, English language sense of a word should be assumed, and not that of any technical body of knowledge or community of practice.

The model described in this specification follows the principles of the Web Ontology Language (OWL). This defines the concept of a 'Class' as a set theory construct and is not to be confused with the usage of the word 'Class' in the UML modeling paradigm. In descriptions aimed as business audiences, we usually use the word 'Thing' in place of this, and on the basis that the OWL library class "Thing" is the ultimate parent of all classes in an OWL model (so they are all things). This also precludes having to explain to a business audience the very nuanced distinctions between UML and OWL Classes. The specialized technical usage of the word 'Thing' to refer to an OWL individual is not the sense used in this Annex.

In this Annex, the term 'class' and 'thing' will be used interchangeably to describe the OWL classes as set theory constructs, that is in the natural language (dictionary) sense in which one speaks of classes of thing (for example in the sentence "what class of locomotive is this?" or "what class of animal is a fish?"). This corresponds to the OWL usage of the term but not (or not without some qualification) to the UML usage of the term.

D.2 Overview

D.2.1 Classes of Thing

In OWL and therefore in FIBO models, membership of a class may be defined intensionally by way of properties which define the membership (the extension) of that class, or extensionally by way of listing the members of the set which makes up that class.

In the model described in this specification, all classes are defined intensionally except where extensional models are unavoidable. The modeling notation employed here supports the definition of extensional classes but this is discouraged except for the definition of classes which are necessarily extensional such as days of the week.

D.2.2 Model relationship to Subject Matter

The formal statement by which everything in the model has an ultimate super-class which is the universal set of 'Thing' is the means by which this model is formally identified as being a business conceptual model and not a data model representation.

In order to preserve the integrity of the model as a model of business concepts, all classes which are added to the model must:

- 1. Be given a superclass (a class with which the new class has a sub-class relationship) from one of the existing classes in the model;
- 2. Represent something in the business domain itself, and
- 3. Represent a set of possible members which in all cases would also be members of the set defined by the superclass in (1)

D.2.3 How to Model New Classes

In modeling semantics, it is a requirement to model each new kind of "Thing" (hereafter referred to as 'classes') in the model according to the following two criteria:

- What kind of thing is this?
- What facts distinguish it from other things?

The consequence of addressing these questions is that for each kind (or class) of thing in the domain of discourse (in this case business entities and legal entities), this will be defined in terms of the following question:

"What is the simplest kind of thing that this is one of?"

By defining classes in terms of simpler kinds of thing, future changes will be additive. This benefit only applies if each class in the model is adequately generalized into some more abstract concept.

Failure to adequately generalize classes of "Thing" in the taxonomic hierarchy will have the result that future additions to that part of the taxonomy may prove to be disruptive. When the model is extended in the future to cover additional concepts, if the model components are not adequately abstracted then it will become necessary to break the existing chain of generalization to interpose new terms to support these new concepts. It is therefore important that modelers exercise imagination in this regard.

D.2.4 Declaring Class Disjointness

A disjointness relationship indicates that two classes of thing are mutually exclusive, that is that members of one may not also be members of the other.

Class disjointness refers to the situation whereby the members of one class may not also be members of another class when there is a disjoint relationship between the two. In OWL this relationship uses the 'isDisjoint' construct.

New 'isDisjoint' relationships should be labeled with the natural language label of "mutually exclusive"

Classes may have several separate sets of sub-classes which are mutually disjoint.

Note that disjointness is inherited through sub-class relationships. If a disjoint is misapplied this may cause inconsistencies. Conversely, if there is an inconsistency and disjointness has been correctly applied, then somewhere in the model there is an incorrect statement which would assert that some individual may be a member of more than one mutually disjoint class. The application of disjoint relationships therefore provides a useful diagnostic for subsequent extensions to the model, provided it is implemented correctly.

D.2.5 How to Model New Facts about Things

There are two kinds of "fact" in the model (in formal modeling terms, two kinds of "Property"):

- 1. Relationship Properties (known in OWL as Object Properties);
- 2. Simple Properties (known in OWL as Datatype Properties)

These are similar in their intent, in that they assert something about the class of which they are a property, but are shown differently in model diagrams.

Facts (properties) should be presented in the model only at the level of the class to which they apply. If a fact is not always applicable or relevant to the meaning of some concept, it should be applied to one or more sub-types of that class

where it would be applicable. Similarly a property should not be applied to sub-classes where they would not always be true.

As an example, vertebrates are a class of things which are an animal and which have a backbone. It would not be appropriate to model the term "has backbone" as an optional property of all animals. Nor would it be sensible to say, for each class of things which is a vertebrate, that this class of vertebrates also has a backbone.

Note that there is a difference here from data modeling. In a data model it may be more efficient to assign a property to a class, make it optional, and then have some sub-classes which use that property and some which do not. This is appropriate for a data model because such a model is not intended to convey the meanings of those classes; rather, the user of the model has to know which sub-classes would have data for that property and which of them would not. In contrast, the semantic model in FIBO is intended to convey the knowledge that such a user would need to have. For this reason, considerations of efficiency which would be brought to bear on a data model design exercise, should not be considered when extending FIBO models.

Impact on Sub-classes

When adding a new Relationship Property or Simple Property to an existing class, ensure that this fact would be true of all the classes that are sub-classes of this class, and that are sub-classes of their classes and so on. If the meaning asserted by the addition of the new property is not necessarily true of all the descendent classes of thing, then it would not be correct to add it to this class. Instead it should be added to those of the sub-classes to which it does apply (that is, those to which it contributes something of the meaning of what it is to be a member of that class).

If there is a clearly identifiable group of those sub-classes for which the property is applicable, then it is possible that these could be grouped together as a new sub-class with that property. However, the addition of such a class, being as it would be interposed into an existing class hierarchy, should be handled with care - this constitutes a disruptive rather than an additive change, and will have different and more stringent change management requirements.

Adding a Relationship Property

Wherever possible, a Relationship Property should be a specialization of another Relationship Property which is already in the model. When adding the Relationship Property, the RDF construct "subPropertyOf" should be used to assert what is the parent property.

The new property should extend or refine the meaning of the parent property in some way.

It is also allowable to have more than one parent property. This is appropriate in cases where the meaning of one Relationship Property is recognizably derivable from the meanings of two or more other Relationship Properties. This construction should be used sparingly and with care.

Types of Relationship Property

In terms of the OWL language, there are a number of distinctions between kinds of relationship which may be asserted in this model. For example, it is possible to assert that a relationship is symmetric, or that it is 'functional'. Functional relationships are relationships where only one individual of the type that's shown as the range of the property, may be that thing.

In the UML modeling environment, the information about what kind of relationship a given relationship is, is provided by means of tagged values.

At present the terms distinguishing different types of relationship are not widely used in the model. If in doubt, relationships should be added without attempting to populate this information.

When adding a new relationship and making it a sub-property of some existing relationship, modelers should check the parent relationship and any of its parents, to verify whether these are defined as being one of these specialized types of OWL object property. If they are, then the new relationship will also take on this type, so modelers must ensure that this would be correct for the relationship being added.

Adding a Simple Property

Simple Properties may only have a range (the object of the predicate) which is a simple information type or an enumerated data range.

The simple information types may be found in the model sub clause "Business Types". These include concepts such as text, numbers, dates and yes/no answers.

Simple Properties should not have ranges which are technical datatypes (the XML primitive datatype set or the datatypes made available within a UML modeling framework). XML primitive datatypes are allowable in RDF/XML based OWL ontologies, and would be used in an operational ontology derived from these models, but for the purposes of business understanding of the model these are all either given aliases (like 'yes/no' for boolean), or have more detailed types derived from them such as the various kinds of number.

There are no "Complex Types" in FIBO. For presentation purposes in different UML editing environments it is possible to consider rendering certain Relationship Properties (OWL object properties) as if they were simple types, i.e. using the UML "attribute" construct, but this is not formally supported in the sub-set of ODM defined in this specification. If this technique is used, such properties must be formally identified as OWL object properties; datatypes properties may not refer to classes which themselves have properties, such as monetary amounts or dated values.

D.2.6 Inverse Relationships

Whenever two relationships are in an inverse pair, this must be indicated by adding a relationship between those relationships, using the OWL construct 'inverseOf'. This should be labeled with the natural language label of 'inverse'.

Many Relationship Properties about things in the real world come in pairs, where one is the inverse of the other. For example "Account held by Account Holder" and "Account Holder holds Account" are two ways of saying the same thing, from the two perspectives of the Account and the Account Holder.

All relationships in the semantic notation used here and in the Semantic Web are unidirectional, that is they are 'triples' of the form Sub verb Object.

This is different to the way relationships are treated in data modeling. The 'ends' of a relationship in a data modeling format may be considered as being analogous to the separate relationships in a semantic model.

When to add these: Where it is considered relevant in defining the meanings of concepts, Relationship Properties (other than symmetric ones - see 'Types of Relationship Property') may also be given an inverse. It is not a formal requirement to indicate all the inverses that may possibly exist. Such relationships should be present in the model and extensions to the model if the two senses are in common use, if they correspond to a named term for which there is a formal definition in use in the financial industry, or if Relationship Properties that are commonly defined for sub-types of the class that they are a fact about, are commonly specified or referred to in the opposite direction to the one which has already been specified.

For this reason, the addition of new classes of thing in the model, given that these specialize existing things, may sometimes require the addition of the inverse of some existing Relationship Property, which was previously implied but not present as a property in the model.

D.2.7 How and When to Use Enumerations

There are two kinds of enumeration in the modeling notation:

- Enumerated Data Range
- Enumerated Class

Enumerated data ranges look a lot like enumerated datatypes in data models. However, these are used differently and will not usually correspond.

The 'Enumerated Data Range' construct should be used to enumerate possible data literals, that is pieces of text, numbers and so on, any one and only one of which may be the literal value of that datatype property for one instance of that class.

Where a data model enumerations may enumerate types of real thing and are frequently used to "flag" some class to say what kind of thing this is, this arrangement cannot be used in the FIBO semantic model. If a class of thing may be of several types, then these should be modeled as distinct classes, each of them a sub-class of the class of thing that they are all types of.

Where a class is to be defined by enumerating its members (extensional definition of the class), then the class itself should be modeled not as an OWL Class but as an OWL Enumeration Class.

D.2.8 Foundations Concepts Usage

Because it was a requirement that classes of thing be abstracted to their simplest possible types, the modeling already carried out in FIBO necessarily required the creation of a set of classes which, by their nature, are not unique to business entities or financial services terms and definitions.

There is a second scenario in which terms are required which are not unique to financial services. This is when a relationships fact (OWL object property) about some business entity has a relationship to something which is not itself a concept unique to the context of the financial services sector.

The terms which are not unique to the financial services sector are maintained in a separate part of the model repository and are given a separate namespace. These are packaged as the FIBO Foundations ontologies. Use of the appropriate terms in these ontologies is normative for this specification, but in many cases these ontologies are being evolved, improved upon and better aligned with other publicly available standard ontologies and with relevant academic work.

In Semantic Web terms, these are mid level ontologies. These are additionally supplemented by the inclusion of an "Upper Ontology" consisting of three sets of underspecified, high level partitions into which all model content is divided.

When adding new classes or Relationship Properties, modelers should seek out and select concepts from within the Foundations ontologies which represent the terms they need to specialize or refer to. They should also recognize and adequately respect the 'Archetype' of that term, if available. In particular, the ontology partitions under which the required archetype term resides should be inspected and understood, in order not to give rise to inconsistencies in the resultant ontology.

New general terms should not be added without first seeking the appropriate terms in these Foundations ontologies or in some recognized external ontology, which must itself be cross referenced using one of the methods described in Annex C (Shared Semantics Treatments), in order to create the necessary relationships.

D.2.9 Content Creation Summary

In summary, there are two scenarios where classes of thing are needed in any ontology for business entities, for financial securities, loans, derivatives and so on:

- The kind of "Thing" which something is;
- Things which are referred to in facts about things.

The first question will lead the modeler to find a more general class of thing of which to make the new class a sub-class. This should be sought initially in the ontology which is being extended, and after exhausting this, in the appropriate Foundations ontology, which must be inspected and fully understood before implementing the new sub-class ('is a') relationship.

The second question will lead the modeler to seek out the appropriate class of thing to which they need to refer. Often, but not necessarily, this will require the creation of some new class of thing. For example, a new class of 'Interest Payment Terms' might be appropriate in order to define a property of a new class of interest-bearing instrument which is defined by way of unique interest payment terms.

Modelers should look in the first instance for some class of thing which is exactly appropriate to the new relationship. For example, concepts like "Monetary Amount" or "Dated Monetary Amount" may be appropriate targets ("Ranges" in Semantic Web parlance) for more than one Relationship Property about more than one class of thing.

In the absence of such a class, modelers should add a suitable sub-class of some existing class of thing which is broader

in meaning but otherwise identical to the class to which the new Relationship Property is to refer. In the interest payment terms example above, they would add a new sub-type of the class which is 'Interest Payment Terms Set' or perhaps 'Fixed Interest Payment Terms Set' or 'Bond Fixed Interest Payment Terms Set' as appropriate. This should be labeled with a suitably business-facing label which uniquely describes it within that ontology and which as far as possible reflects what is unique about its meaning (note that meanings do not follow from these labels, but that business comprehension of the model follows from their allocation).

Where a term is not available for specialization within the ontology which the modeler is extending, these are to be found in the FIBO Foundations ontologies, which have been created for the purpose of providing such terms. These are ontologies of things which are not specific to financial services. These include legal concepts like contracts, business concepts such as service provision, as well as an extensive set of concepts for times, dates, mathematical constructs, events and activities, and so on.

If a suitable general term cannot be found then it may be necessary to extend one of the FIBO Foundations ontologies. This should be undertaken as a collaborative effort since this term will almost certainly be needed again in the future and by others. Such terms should be defined with formal reference to other, publicly available ontologies (these being defined either in Semantic Web formats or in some presentation, notation of theoretical grounding which makes it unambiguously clear that the terms in question are not part of a data model or other logical design).

D.3 Presentation Considerations

The presentation conformance requirements described in this specification are mainly a consideration for those creating or setting up editing environments in different modeling tools, and are not covered in this Annex. However, in the course of creating extensions to the model content there are a number of considerations which the modeler should keep in mind, as described in this sub clause.

D.3.1 Labeling

All classes, Relationship Properties and Simple Properties should be given natural language labels. These should be rendered with spaces just as normal text is written.

These labels should conform to the following style requirements:

- Classes: Names should be in Upper Sentence Case
 - o Abbreviations (if used) should be in their normal upper case rendition e.g. ABC.
 - o Small words (of, and etc.) should also be capitalized (this is to enable technical users to compress the names without loss of sense)
- Relationship Properties: Names should take the form Subject predicate Object with the casing as shown
 - o Subject and Object to have the full name of the classes themselves except where this is cumbersome
 - The predicate (verb part) of the relationship name should be in all lower case, with spaces
 - If possible, relationship lines (which are displayed in 'simple' diagrams that don't have the boxes that come with the Relationship Properties), should be labeled with only the predicate.
- Simple Properties: Names should be in Upper Sentence Case
- Other types of "Thing" construct (OWL Union Classes, Intersection Classes, Enumerated Classes and Enumerated Data Ranges) should follow the same naming convention as classes.

In addition to the above constructs, which define the terms in the business domain, there are a number of built in constructs which make additional statements, in set theory terms, about the classes and properties. These should be labeled as follows:

• Logical Union relationships: these are rendered using the UML construct of a generalization set (UML "GeneralizationSet"). Such sets have one name. This name should be a natural language label, with spaces and

in lower case. The label should make clear the sense that it is a union relationship defining the logical union of the classes which participate in the generalization set, for example by ending the label with the word 'union'.

- Disjoints (OWL disjointWith): should always have the label "mutually exclusive"
- Inverses of relationships (OWL inverseOf): should always have the label "inverse"

D.3.2 Ontologies

These are implemented using the UML base class of 'Package'. Names for these should be in Upper Sentence Case. Wherever possible short or one word names should be considered.

D.3.3 UML Considerations

UML Diagrams

Diagrams are not transferred from any modeling environment into or out of the model repository. Diagrams are to be created by the modeler for presentation to business domain experts in the area in which they are working, or in the case of new submissions of the model content for future updates, to the wider community, and must be designed to be readable by business domain experts.

UML Notation

No explicitly UML notation should be present on any diagram.

The guiding principle here is one of language: any diagram which includes anything which belongs in or looks as though it belongs in some technical notation, will signal to the business reviewer that this diagram is in a language for which they have had no formal training. No matter how obvious the meaning of a diagram appears to be, the appearance of any technical notation means that it will appear to be something that requires some technical training to parse its meaning.

This means that

- no repurposed punctuation marks may be present on the diagrams. For example:
 - o no curly braces and therefore no OCL
 - o no guillemets so stereotype indications must be disabled
 - o no plus signs at the ends of relationships or next to attribute names
- UML class partitions that are unused (such as the operations partition) must be made invisible either by manually resizing the class box until the extra line disappears, or by some other means;
- Exceptions may be made for relationship multiplicities, but the implications of these must be clearly explained to business domain experts who are expected to review the model content
- The Generalization arrowhead is an exception to the above: although this represents a technical notation (Generalization in UML), its meaning is more universal and can be explained to business domain experts ahead of any review. Such explanations must either reference Aristotelian syllogisms or be described in terms of the "is a" relationship with examples from natural taxonomy, depending on the knowledge of the business audience, but should not make reference to UML or words like Generalization or transitivity.
- Namespace indications: in some tools these are indicated with a double colon, which breaks the first rule above.
 Diagrams with these on may be created and maintained so that maintainers of the content can keep track of what is in what ontology, but these diagrams should not be considered as suitable for general business domain distribution.

Diagram Layout

Modelers should take care to lay out these in a clear and consistent way.

Generalization relationships should be laid out with the "arrowhead" pointing vertically upwards, in either the vertical tree style or direct style of routing. This is because this relationship, while technology neutral (it represents a basic Aristotelian syllogism), has to be explained to business domain experts and should therefore be presented in the same visual layout in which it has been explained, namely to represent taxonomic hierarchies with the most general terms at the top and the most specific at the bottom. These generalization relationships should never be drawn or found pointing downwards or sideways.

Where possible, the physical arrangement of the concepts in a diagram should try to follow the layout of the corresponding concepts in the archetype diagrams for those concepts.

Where large numbers of concepts are found in the same ontology, modelers should try to create separate diagrams which emphasize separate aspects of the subject matter (for example segregating contractual terms from legal obligations, or events from parties).

The relationship sub-property relationships are a particular hazard to creating clear, clean diagrams. However, these should rarely be shown to business domain experts. Where practicable, modelers are encouraged to create, for each separate thematic diagram, a set of three diagrams: one with all the material that needed to be modeled, one without the class component of the Relationship Properties, and one without the Simple Properties (compressing the class glyph as needed to remove the appearance of the attributes partition boundary).

Diagram Notes

Diagrams may also be decorated with informative notes. However, nothing of substance to the model content should be included in these, since these will not be retained when the model is transferred into the model repository or into other modeling environments.

UML Diagram Boundaries

As with notes, these may be included in business diagrams to aid in readability, but these UML boundaries do not form part of the model content and are not retained when the model content is transferred between environments.

UML Packages

UML Packages do not form part of the model, unless the package is stereotyped as an OWL Ontology.

OWL ontology packages may not be nested within other OWL ontology packages.

Modelers may arrange packages as appropriate for the usage to which they intend to put the model, and as part of this they may elect to make hierarchical structures of packages. Packages which are not stereotypes as OWL ontologies may be used for the purposes of such organization. Such packages may only contain other such packages or OWL ontology packages (that is, they should contain no loose classes or other constructs). Such packages do not form part of the model content, and will not be retained when the model content is transferred between environments.

No relationships between packages should be interpreted as, or created to imply, any relationship between ontologies.

All ontology imports must be explicitly modeled using the ODM "owlImports" construct. Each ontology should contain a diagram showing the full set of OWL imports required for that ontology, up to and including the "Lattice" ontology.

Annex E: Creating Applications with FIBO (Informative)

E1. Introduction

This annex contains guidelines on the production of operational applications that take the various FIBO Business Conceptual Ontologies as a point of reference. Such applications include operational OWL ontologies and applications based on conventional data models. The sub clauses below set out the overarching principles for creating such applications, and itemize the things to consider when deriving operational ontologies or logical data models from the content in those FIBO specifications.

E.1.1 Principles

These are the basic principles in order to avoid making assertions which contradict those assertions already made in FIBO:

- 1. It is not necessary to include all the ancestor classes but disjoints asserted between those ancestor classes must be respected
- 2. Two classes cannot be introduced into the same logical class hierarchy which have ancestors which are disjoint in FIBO. This is because otherwise it becomes possible to introduce contradictions or data structures which correspond to contradictory or untrue (or absurd) facts about the world.
- 3. Relationships which have restrictions defined for them (for example functional object properties) may not be extended to have looser multiplicity in logical data models but they may be further restricted.
- 4. New facts or relationships should not be introduced which directly contradict some fact in the FIBO terms which are used, or in any FIBO terms which are not directly used but which have a bearing on the terms which are used.

E.1.2 Operational Ontologies

The following questions are to be considered when creating an operational OWL ontology using terms set out in one or more of the FIBO Business Conceptual Ontologies:

- When to replace an object property with a Boolean
- Shortening the inheritance hierarchy
- Using independent things without relative things
- Redefining Relative Things as Independent Things
 - o This is valid when the context of the application matches the "Mediating Thing" that is the context in which the Relative Thing is defined
 - o Example: Legal Entity is a relative thing but for an application whose scope is constrained to one jurisdiction or LEI issuer, it can be treated as an Independent Thing
- Use of property chains
- Extraction of single-inheritance (monohierarchical) taxonomy
 - o May also be conformant, as a sub-set of the FIBO material
- OWL Restrictions versus rdfsSubPropertyOf relations between multiple object properties.

E.1.3 Conventional Applications

The following questions are to be considered when creating a logical data model using terms set out in one or more of the FIBO Business Conceptual Ontologies:

- Possible architectures
 - o Use of semantically under-specified classes, with enumerations to identify semantics
 - Other styles –e.g. a direct rendition of the ontology with addition of database keys
- General
- Enumerations don't have mixed semantics in one enumerated datatype (causes combinational explosions)
- o Text: when to collapse a chain of properties that end in a text field, with just an attribute that has text as a datatype
- Combining pairs of object properties into one association with the object property names as the labels of the ends of the association
- UML considerations
 - When to render object properties with a specific archetype, as UML Associations or Generalizations
 - o Multiplicity
- Relative Things
 - These may be treated as independent classes when the context of the application matches the "Mediating Thing" that is the context in which the Relative Thing is defined
 - o Example: Legal Entity is a relative thing but for an application whose scope is constrained to one jurisdiction or LEI issuer, it can be treated as an Independent Thing
- Localization within a part of the taxonomy
 - Patterns for taking a starting point within the hierarchy (e.g. MBS versus Bond versus Security), and navigating each of the object properties that apply at that level, navigating downwards (but not upwards) in the taxonomy of things that are the range of the object property, and defining these as the full possible scope of the model
- Extraction via Context
 - o From a given "Mediating Thing", navigate to each of the "Relative Things" defined in that context, and each of the "Independent Things" that may take on the "identity" property of those relative things this should result in a set of all and only those things needed for the application
