Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

International Standards are drafted in accordance with the rules given in the ISO/IEC Directives, Part 2.

The main task of technical committees is to prepare International Standards. Draft International Standards adopted by the technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75 % of the member bodies casting a vote.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights.

ISO/IEC 19507 was prepared by Technical Committee ISO/IEC JTC1, Information technology, in collaboration with the Object Management Group (OMG), following the submission and processing as a Publicly Available Specification (PAS) of the OMG Object Constraint Language specification Version 2.3.1.

ISO/IEC 19507, under the general title Information technology - Open distributed processing - Object Constraint Language specification (OCL), apart from this introductory material is identical with that for the OMG specification for Object Constraint Language, v2.3.1.
Introduction

The rapid growth of distributed processing has led to a need for a coordinating framework for this standardization and ITU-T Recommendations X.901-904 | ISO/IEC 10746, the Reference Model of Open Distributed Processing (RM-ODP) provides such a framework. It defines an architecture within which support of distribution, interoperability, and portability can be integrated.

RM-ODP Part 2 (ISO/IEC 10746-2) defines the foundational concepts and modeling framework for describing distributed systems. The scopes and objectives of the RM-ODP Part 2 and the UML, while related, are not the same and, in a number of cases, the RM-ODP Part 2 and the UML specification use the same term for concepts that are related but not identical (e.g., interface). Nevertheless, a specification using the Part 2 modeling concepts can be expressed using UML with appropriate extensions (using stereotypes, tags, and constraints).

RM-ODP Part 3 (ISO/IEC 10746-3) specifies a generic architecture of open distributed systems, expressed using the foundational concepts and framework defined in Part 2. Given the relation between UML as a modeling language and Part 2 of the RM ODP standard, it is easy to show that UML is suitable as a notation for the individual viewpoint specifications defined by the RM-ODP.

OCL Language

OCL is a pure specification language; therefore, an OCL expression is guaranteed to be without side effects. When an OCL expression is evaluated, it simply returns a value. It cannot change anything in the model. This means that the state of the system will never change because of the evaluation of an OCL expression, even though an OCL expression can be used to specify a state change (e.g., in a post-condition).

OCL is not a programming language; therefore, it is not possible to write program logic or flow control in OCL. You cannot invoke processes or activate non-query operations within OCL. Because OCL is a modeling language in the first place, OCL expressions are not by definition directly executable.

OCL is a typed language so that each OCL expression has a type. To be well formed, an OCL expression must conform to the type conformance rules of the language. For example, you cannot compare an Integer with a String. Each Classifier defined within a UML model represents a distinct OCL type. In addition, OCL includes a set of supplementary predefined types. These are described in Clause 11 (“The OCL Standard Library”).
Information technology - Object Management Group
Object Constraint Language (OCL)

1 Scope

This International Standard defines the Object Constraint Language (OCL), version 2.3.1. OCL version 2.3.1 is the version of OCL that is aligned with UML 2.3 and MOF 2.0.

2 Conformance

The UML 2.0 Infrastructure and the MOF 2.0 Core specifications that were developed in parallel with this OCL 2.3.1 specification share a common core. The OCL specification contains a well-defined and named subset of OCL that is defined purely based on the common core of UML and MOF. This allows this subset of OCL to be used with both the MOF and the UML, while the full specification can be used with the UML only.

The following compliance points are distinguished for both parts.

1. Syntax compliance: The tool can read and write OCL expressions in accordance with the grammar, including validating its type conformance and conformance of well-formedness rules against a model.

2. XMI compliance: The tool can exchange OCL expressions using XMI.

3. Evaluation compliance: The tool evaluates OCL expressions in accordance with the semantics clause. The following additional compliance points are optional for OCL evaluators, as they are dependent on the technical platform on which they are evaluated:
   • allInstances()
   • pre-values and oclIsNew() in postconditions
   • OclMessage
   • navigating across non-navigable associations
   • accessing private and protected features of an object

The following table shows the possible compliance points. Each tool is expected to fill in this table to specify which compliance points are supported.

3.2 Informative References

The following specifications are referenced in informative text:

4 Terms and Definitions

There are no formal definitions that are taken from other documents.

5 Notational Conventions

There are no symbols defined.

6 Additional Information

6.1 Changes to Adopted OMG Specifications

This International Standard replaces the specification of OCL given in OCL 2.2.

The version of OCL specified in ISO/IEC 19501:2005 is intended for use in models based on UML 1.4.1 and UML 1.5. However, use of the OCL specified by ISO/IEC 19501:2005 is not prescribed by this specification.

The version of OCL specified in this International Standard is not directly applicable to models based on ISO/IEC 19501:2005.

6.2 Structure of the Specification

This International Standard is divided into several clauses.

- The OCL Language Description clause gives an informal description of OCL. This clause is not normative, but meant to be explanatory.
- Clause 8 (“Abstract Syntax”) describes the abstract syntax of OCL using a MOF 2.0 compliant metamodel. This is the same approach as used in the UML specifications. The metamodel is MOF compliant in the sense that it only uses constructs that are defined in the MOF.
- Clause 9 (“Concrete Syntax”) describes the canonical concrete syntax using an attributed EBNF grammar. This syntax is mapped onto the abstract syntax, achieving a complete separation between concrete and abstract syntax.
- Clause 10 (“Semantics Described using UML”) describes the semantics for OCL using UML.
- In Clause 11 (“The OCL Standard Library”) the OCL Standard Library is described. This defines type like Integer, Boolean, etc. and all the collection types. OCL is not a stand-alone language, but an integral part of the UML. An OCL expression needs to be placed within the context of a UML model.
- Clause 12 (“The Use of Ocl Expressions in UML Models”) describes a number of places within the UML where OCL expressions can be used.
- Clause 13 (“Basic OCL and Essential OCL”) defines the adaptation of the OCL metamodel when used in particular context of Core::Basic infrastructure library package and in the context of EMOF.
- Annex A (Semantics), Annex B (Bibliography), and Annex C (Legal Information)

7 OCL Language Description

7.1 General

This clause introduces the Object Constraint Language (OCL), a formal language used to describe expressions on UML models. These expressions typically specify invariant conditions that must hold for the system being modeled or queries over objects described in a model. Note that when the OCL expressions are evaluated, they do not have side effects (i.e., their evaluation cannot alter the state of the corresponding executing system).

OCL expressions can be used to specify operations / actions that, when executed, do alter the state of the system. UML modelers can use OCL to specify application-specific constraints in their models. UML modelers can also use OCL to specify queries on the UML model, which are completely programming language independent.

Note - This clause is informative only and not normative.

7.2 Why OCL?

A UML diagram, such as a class diagram, is typically not refined enough to provide all the relevant aspects of a specification. There is, among other things, a need to describe additional constraints about the objects in the model. Such constraints are often described in natural language. Practice has shown that this will always result in ambiguities. In order to write unambiguous constraints, so-called formal languages have been developed. The disadvantage of traditional formal languages is that they are usable to persons with a strong mathematical background, but difficult for the average business or system modeler to use.

OCL has been developed to fill this gap. It is a formal language that remains easy to read and write. It has been developed as a business modeling language within the IBM Insurance division, and has its roots in the Syntropy method.

OCL is a pure specification language; therefore, an OCL expression is guaranteed to be without side effects. When an OCL expression is evaluated, it simply returns a value. It cannot change anything in the model. This means that the state of the system will never change because of the evaluation of an OCL expression, even though an OCL expression can be used to specify a state change (e.g., in a post-condition).

OCL is not a programming language; therefore, it is not possible to write program logic or flow control in OCL. You cannot invoke processes or activate non-query operations within OCL. Because OCL is a modeling language in the first place, OCL expressions are not by definition directly executable.

OCL is a typed language so that each OCL expression has a type. To be well formed, an OCL expression must conform to the type conformance rules of the language. For example, you cannot compare an Integer with a String. Each Classifier defined within a UML model represents a distinct OCL type. In addition, OCL includes a set of supplementary predefined types. These are described in Clause 11 (“The OCL Standard Library”).

As a specification language, all implementation issues are out of scope and cannot be expressed in OCL.

The evaluation of an OCL expression is instantaneous. This means that the states of objects in a model cannot change during evaluation.

7.2.1 Where to Use OCL

OCL can be used for a number of different purposes:

- as a query language,
ISO/IEC 19507:2012(E)

- to specify invariants on classes and types in the class model,
- to specify type invariant for Stereotypes,
- to describe pre- and post conditions on Operations and Methods,
- to describe Guards,
- to specify target (sets) for messages and actions,
- to specify constraints on operations, and
- to specify derivation rules for attributes for any expression over a UML model.

7.3 Introduction

7.3.1 Legend

Text written in the typeface as shown below is an OCL expression.

'This is an OCL expression'

The context keyword introduces the context for the expression. The keyword inv, pre, and post denote the stereotypes, respectively «invariant», «precondition», and «postcondition» of the constraint. The actual OCL expression comes after the colon.

    context TypeName inv:
    'this is an OCL expression with stereotype <<invariant>> in the context of TypeName' = 'another string'

In the examples the keywords of OCL are written in boldface. The boldface has no formal meaning, but is used to make the expressions more readable. OCL expressions are written using ASCII characters only.

Words in Italics within the main text of the paragraphs refer to parts of OCL expressions.

7.3.2 Example Class Diagram

The diagram below is used in the examples in this clause.
7.3.3 Character Set

OCL text comprises characters in the UNICODE character set. In particular, string literals, comments, and the names of types, features, and other elements in the UML model may contain any valid UNICODE character.

7.4 Relation to the UML Metamodel

7.4.1 Self

Each OCL expression is written in the context of an instance of a specific type. In an OCL expression, the reserved word self is used to refer to the contextual instance. For example, if the context is Company, then self refers to an instance of Company.

7.4.2 Specifying the UML Context

The context of an OCL expression within a UML model can be specified through a so-called context declaration at the beginning of an OCL expression. The context declaration of the constraints in the following sub clauses is shown.

If the constraint is shown in a diagram, with the proper stereotype and the dashed lines to connect it to its contextual element, there is no need for an explicit context declaration in the test of the constraint. The context declaration is optional.
7.4.3 Invariants

The OCL expression can be part of an Invariant, which is a Constraint stereotyped as an «invariant». When the invariant is associated with a Classifier, the latter is referred to as a “type” in this clause. An OCL expression is an invariant of the type and must be true for all instances of that type at any time. (Note that all OCL expressions that express invariants are of the type Boolean.)

For example, if in the context of the Company type in Figure 7.1, the following expression would specify an invariant that the number of employees must always exceed 50:

```
self.numberOfEmployees > 50
```

where `self` is an instance of type Company. (We can view `self` as the object from where we start evaluating the expression.) This invariant holds for every instance of the Company type.

The type of the contextual instance of an OCL expression, which is part of an invariant, is written with the `context` keyword, followed by the name of the type as follows. The label `inv:` declares the constraint to be an «invariant» constraint.

```
context Company inv:
    self.numberOfEmployees > 50
```

In most cases, the keyword `self` can be dropped because the context is clear, as in the above examples. As an alternative for `self`, a different name can be defined playing the part of `self`. For example:

```
context c : Company inv:
    c.numberOfEmployees > 50
```

This invariant is equivalent to the previous one.

Optionally, the name of the constraint may be written after the `inv` keyword, allowing the constraint to be referenced by name. In the following example the name of the constraint is `enoughEmployees`.

```
context c : Company inv enoughEmployees:
    c.numberOfEmployees > 50
```

7.4.4 Pre- and Postconditions

The OCL expression can be part of a Precondition or Postcondition, corresponding to «precondition» and «postcondition» stereotypes of Constraint associated with an Operation or other behavioral feature. The contextual instance `self` then is an instance of the type that owns the operation or method as a feature. The context declaration in OCL uses the `context` keyword, followed by the type and operation declaration. The stereotype of constraint is shown by putting the labels ‘pre:’ and ‘post:’ before the actual Preconditions and Postconditions. For example:

```
context Typename::operationName(param1 : Type1, ...): ReturnType
    pre:  param1 > ...
    post:  result = ...
```

The name `self` can be used in the expression referring to the object on which the operation was called. The reserved word `result` denotes the result of the operation, if there is one. The names of the parameters (`param1`) can also be used in the OCL expression. In the example diagram, we can write:

```
context Person::income(d : Date): Integer
    post:  result = 5000
```
Optionally, the name of the precondition or postcondition may be written after the `pre` or `post` keyword, allowing the constraint to be referenced by name. In the following example the name of the precondition is `parameterOk` and the name of the postcondition is `resultOk`. In the UML metamodel, these names are the values of the attribute `name` of the metaclass `Constraint` that is inherited from `ModelElement`.

```ocl
class Typename::operationName(param1 : Type1, ...): ReturnType
  context Typename::operationName(param1 : Type1, ...): ReturnType
  pre parameterOk: param1 > ...
  post resultOk : result = ...
endclass
```

### 7.4.5 Package Context

The above context declaration is precise enough when the package in which the Classifier belongs is clear from the environment. To specify explicitly in which package invariant, pre or postcondition Constraints belong, these constraints can be enclosed between `package` and `endpackage` statements. The package statements have the syntax:

```ocl
package Package::SubPackage

context X inv:
  ... some invariant ...
context X::operationName(.,..)
  pre: ... some precondition ...
endpackage
```

An OCL file (or stream) may contain any number package statements, thus allowing all invariant, preconditions, and postconditions to be written and stored in one file. This file may co-exist with a UML model as a separate entity.

### 7.4.6 Operation Body Expression

An OCL expression may be used to indicate the result of a query operation. This can be done using the following syntax:

```ocl
context Typename::operationName(param1 : Type1, ...): ReturnType
  body: -- some expression
```

The expression must conform to the result type of the operation. Like in the pre- and postconditions, the parameters may be used in the expression. Pre-, and postconditions, and body expressions may be mixed together after one operation context. For example:

```ocl
context Person::getCurrentSpouse() : Person
  pre: self.isMarried = true
  body: self.marriages->select( m | m.ended = false ).spouse
```

### 7.4.7 Initial and Derived Values

An OCL expression may be used to indicate the initial or derived value of an attribute or association end. This can be done using the following syntax:

```ocl
context Typename::attributeName: Type
  init: -- some expression representing the initial value

context Typename::assocRoleName: Type
  derive: -- some expression representing the derivation rule
```
The expression must conform to the result type of the attribute. In the case the context is an association end the expression must conform to the classifier at that end when the multiplicity is at most one, or Set, or OrderedSet when the multiplicity may be more than one. Initial and derivation expressions may be mixed together after one context. For example:

```oclnote
context Person::income : Integer
init:   parents.income->sum() * 1% -- pocket allowance
derive: if underAge
       then parents.income->sum() * 1% -- pocket allowance
       else job.salary                 -- income from regular job
       endif
```

The derivation constraint must be satisfied at any time, hence the derivation includes the initialization. Both are allowed on the same property but they must not be contradictory. For each property there should be at most one initialization constraint and at most one derivation constraint.

### 7.4.8 Other Types of Expressions

Any OCL expression can be used as the value for an attribute of the UML metaclass Expression or one of its subtypes. In that case, the semantics sub clause describes the meaning of the expression. A special subclass of Expression, called ExpressionInOcl is used for this purpose. See Clause 12 “The Use of OCL Expressions in UML Models” for a definition.

### 7.5 Basic Values and Types

In OCL, a number of basic types are predefined and available to the modeler at all times. These predefined value types are independent of any object model and are part of the definition of OCL.

The most basic value in OCL is a value of one of the basic types. The basic types of OCL, with corresponding examples of their values, are shown in the following table.

#### Table 7.1- Basic OCL types and their values

<table>
<thead>
<tr>
<th>type</th>
<th>values</th>
<th>consistent with implementation definitions</th>
</tr>
</thead>
<tbody>
<tr>
<td>OclInvalid</td>
<td>invalid</td>
<td></td>
</tr>
<tr>
<td>OclVoid</td>
<td>null, invalid</td>
<td></td>
</tr>
<tr>
<td>Boolean</td>
<td>true, false</td>
<td>(MOF) <a href="http://www.w3.org/TR/xmlschema-2/#boolean">http://www.w3.org/TR/xmlschema-2/#boolean</a></td>
</tr>
<tr>
<td>Integer</td>
<td>1, -5, 2, 34, 26524, ...</td>
<td>(MOF) <a href="http://www.w3.org/TR/xmlschema-2/#integer">http://www.w3.org/TR/xmlschema-2/#integer</a></td>
</tr>
<tr>
<td>Real</td>
<td>1.5, 3.14, ...</td>
<td><a href="http://www.w3.org/TR/xmlschema-2/#double">http://www.w3.org/TR/xmlschema-2/#double</a></td>
</tr>
<tr>
<td>String</td>
<td>'To be or not to be...'</td>
<td>(MOF) <a href="http://www.w3.org/TR/xmlschema-2/#string">http://www.w3.org/TR/xmlschema-2/#string</a></td>
</tr>
<tr>
<td>UnlimitedNatural</td>
<td>0, 1, 2, 42, ..., *</td>
<td><a href="http://www.w3.org/TR/xmlschema-2/#nonNegativeInteger">http://www.w3.org/TR/xmlschema-2/#nonNegativeInteger</a></td>
</tr>
</tbody>
</table>

OCL defines a number of operations on the predefined types. Table 7.2 gives some examples of the operations on the predefined types. See 11.4, 'Primitive Types’ for a complete list of all operations.

#### Table 7.2- Examples of operations on the predefined types

<table>
<thead>
<tr>
<th>type</th>
<th>operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>*, +, -, /, abs()</td>
</tr>
<tr>
<td>Real</td>
<td>*, +, -, /, floor()</td>
</tr>
</tbody>
</table>
Collection, Set, Bag, Sequence, and Tuple are basic types as well. Their specifics will be described in the upcoming subclauses.

Multiple adjacent strings are concatenated allowing a long string to be specified on multiple lines.

'This is a '          -- 'concatenated string'          -- 'This is a concatenated string'

Unicode characters are used within single quoted sequences, with the following backslash based escape sequences used to define backslash and other characters.

\b          -- backspace
\t          -- horizontal tab
\n          -- linefeed
\f          -- form feed
\r          -- carriage return
\'          -- double quote
\"          -- single quote
\\          -- backslash
\xhh          -- #x00 to #xFF
\uhhhh          -- #x0000 to #xFFFF

where h is a hex digit: 0 to 9, A to F or a to f.

Reserved words such as true and arbitrary awkward spellings may be used as names by enclosing the name in underscore-prefixed single quotes.

self.'if' = 'tabbed	variable.'spaced operation'()

### 7.5.1 Types from the UML Model

Each OCL expression is written in the context of a UML model, a number of classifiers (types/classes, ...), their features and associations, and their generalizations. All classifiers from the UML model are types in the OCL expressions that are attached to the model.

### 7.5.2 Enumeration Types

Enumerations are Datatypes in UML and have a name, just like any other Classifier. An enumeration defines a number of enumeration literals that are the possible values of the enumeration. Within OCL one can refer to the value of an enumeration. When we have Datatype named Gender in the example model with values ‘female’ or ‘male’ they can be used as follows:

context Person inv: gender = Gender::male

### 7.5.3 Let Expressions

Sometimes a sub-expression is used more than once in a constraint. The let expression allows one to define a variable that can be used in the constraint.

context Person inv:

<table>
<thead>
<tr>
<th>Table 7.2- Examples of operations on the predefined types</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Boolean</strong></td>
</tr>
<tr>
<td><strong>String</strong></td>
</tr>
<tr>
<td><strong>UnlimitedNatural</strong></td>
</tr>
</tbody>
</table>

© ISO/IEC 2012 - All rights reserved
A let expression may be included in any kind of OCL expression. It is only known within this specific expression. A variable declaration inside a let must have a declared type and an initial value.

### 7.5.4 Additional operations/attributes through «definition» expressions

The Let expression allows a variable to be used in one Ocl expression. To enable reuse of variables/operations over multiple OCL expressions one can use a Constraint with the stereotype «definition», in which helper variables/operations are defined. This «definition» Constraint must be attached to a Classifier and may only contain variable and/or operation definitions, nothing else. All variables and operations defined in the «definition» constraint are known in the same context as where any property of the Classifier can be used. Such variables and operations are attributes and operations with stereotype «OclHelper» of the classifier. They are used in an OCL expression in exactly the same way as normal attributes or operations are used. The syntax of the attribute or operation definitions is similar to the Let expression, but each attribute and operation definition is prefixed with the keyword ‘def’ as shown below.

```ocl
class Person
  def : income : Integer = self.job.salary->sum()
  def : nickname : String = 'Little Red Rooster'
  def : hasTitle(t : String) : Boolean = self.job->exists(title = t)
endclass
```

Operations or attributes defined by "definitions expressions" may be static (classifier scoped). In that case the static keyword should be used before "def."

```ocl
class MyClass
  static def : globalId() : Integer = ...
endclass
```

The names of the attributes / operations in a let expression may not conflict with the names of respective attributes/associationEnds and operations of the Classifier.

Using this definition syntax is identical to defining an attribute/operation in the UML with stereotype «OclHelper» with an attached OCL constraint for its derivation.

### 7.5.5 Type Conformance

OCL is a typed language and the basic value types are organized in a type hierarchy. This hierarchy determines conformance of the different types to each other. You cannot, for example, compare an Integer with a Boolean or a String.

An OCL expression in which all the types conform is a valid expression. An OCL expression in which the types don’t conform is an invalid expression. It contains a type conformance error. A type `type1` conforms to a type `type2` when an instance of `type1` can be substituted at each place where an instance of `type2` is expected. The type conformance rules for types in the class diagrams are simple.

- Each type conforms to each of its supertypes.
- Type conformance is transitive: if `type1` conforms to `type2`, and `type2` conforms to `type3`, then `type1` conforms to `type3`. 
The effect of this is that a type conforms to its supertype, and all the supertypes above. The type conformance rules for the types from the OCL Standard Library are listed in Table 7.3., where the third column specifies an additional condition which must be satisfied by the involved types to verify the type conformance rule.

Although UnlimitedNatural conforms to Integer, ‘*’ is an invalid Integer, so that the evaluation of the expression ‘1 + *’ results in invalid.

The conformance relation between the collection types only holds if they are collections of element types that conform to each other. See 7.6.13, ‘Collection Type Hierarchy and Type Conformance Rules’ for the complete conformance rules for collections.

Table 7.4 provides examples of valid and invalid expressions.

### Table 7.3- Type conformance rules

<table>
<thead>
<tr>
<th>Type</th>
<th>Conforms to/Is a subtype of</th>
<th>Condition</th>
</tr>
</thead>

</tbody>
</table>

#### 7.5.6 Re-typing or Casting

In some circumstances, it is desirable to use a property of an object that is defined on a subtype of the current known type of the object. Because the property is not defined on the current known type, this results in a type conformance error.

When it is certain that the actual type of the object is the subtype, the object can be re-typed using the operation oclAsType(Classifier). This operation results in the same object, but the known type is the argument Classifier. When there is an object object of type Type1 and Type2 is another type, it is allowed to write:

```java
object.oclAsType(Type2) --- changes the static type of the expression to Type2
```

An object can only be re-typed to a type to which it conforms. If the actual type of the object, at evaluation time, is not a subtype of the type to which it is re-typed, then the result of oclAsType is invalid.
Casting provides visibility, at parse time, of features not defined in the context of an expression's static type. It does not coerce objects to instances of another type, nor can it provide access to hidden or overridden features of a type. For this, the feature call is qualified by the name of the type (a path name, if necessary) whose definition of the feature is to be accessed.

For example, if class Employee redefines the age() : Integer operation of the Person class, a constraint may access the Person definition as in

```plaintext
context Employee
inv: self.age() <= self.Person::age()
```

For clarity, the qualified form may only be used with an explicit source expression.

### 7.5.7 Precedence Rules

The precedence order for the operations, starting with highest precedence, in OCL is:

- literal and variable expressions, "(" and ")", "if-then-else-endif"
- "let-in"
- @pre
- call expressions: "^", "^^", "." and "->"
- unary "not" and unary "-"
- "*" and "/"
- "+" and binary "-"
- "+", ">", "<", ">=", "<<", ">="
- ">=", "><"
- "and"
- "or"
- "xor"
- "implies"
- "in"

All infix operators are left associative, equal precedence operators are evaluated left to right.

A let expression is both high precedence and low precedence; high on the left so that a let expression behaves as an atomic value in operations, low on the right so that the in-expression can be an arbitrary expression. "a + let ... in a + let ... in a + a" is "a + (let ... in (a + (let ... in (a + a)))."

Parentheses "(" and ")" can be used to change precedence and associativity.

### 7.5.8 Use of Infix Operators

The use of infix operators is allowed in OCL. The operators '+', '-', '*', '/',' <', '>',' <=', '>=', '==', '!=', 'and',' or',' xor',' implies',' in' are used as infix operators. If a type defines one of those operators with the correct signature, they will be used as infix operators. The expression:

```plaintext
a + b
```

is equal to the expression:
that is, invoking the “+” operation on a with b as the parameter to the operation.

The infix operators defined for a type must have exactly one parameter. For the infix operators ‘<,’ ‘>,’ ‘<=,’ ‘>=,’ ‘<>,’ ‘and,’ ‘or,’ and ‘xor’ the return type must be Boolean.

### 7.5.9 Keywords

Keywords in OCL are reserved words. That means that the keywords cannot occur as a name. A reserved word may be used as the name of a package, a type, a feature, a variable or a constraint by enclosing the word in underscore-prefixed single quotes. The list of keywords is shown below:

- and
- body
- context
- def
- derive
- else
- endif
- endpackage
- false
- if
- implies
- in
- init
- inv
- invalid
- let
- not
- null
- or
- package
- post
- pre
- self
- static
- then
- true
- xor

The following words are restricted. A restricted word can only be used as a name when preceded by a “::”. A restricted word may also be used by enclosing the word in underscore-prefixed single quotes.

- Bag
- Boolean
- Collection
- Integer
- OclAny
- OclInvalid
- OclMessage
- OclVoid
- OrderedSet
- Real
- Sequence
- Set
Note that operation names such as iterate, forAll, and oclType are not reserved or restricted.

### 7.5.10 Comment

Comments in OCL are written following two successive dashes (minus signs). Everything immediately following the two dashes up to and including the end of line is part of the comment.

For example:

```
-- this is a comment
```

### 7.5.11 Invalid Values

Some expressions will, when evaluated, have an invalid value. For instance, typecasting with oclAsType() to a type that the object does not support or getting the ->first() element of an empty collection will result in invalid. In general, an expression where one of the parts is null or invalid will itself be invalid. There are some important exceptions to this rule, however. First, there are the logical operators:

- True OR-ed with anything is True
- False AND-ed with anything is False
- False IMPLIES anything is True
- anything IMPLIES True is True

The rules for OR and AND are valid irrespective of the order of the arguments and they are valid whether the value of the other sub-expression is known or not.

The IF-expression is another exception. It will be valid as long as the chosen branch is valid, irrespective of the value of the other branch.

Finally, there is an explicit operation for testing if the value of an expression is undefined. oclIsUndefined() is an operation on OclAny that results in True if its argument is null or invalid and False otherwise.

### 7.6 Objects and Properties

OCL expressions can refer to Classifiers, e.g., types, classes, interfaces, associations (acting as types), and datatypes. Also all attributes, association-ends, methods, and operations without side effects that are defined on these types, etc. can be used. In a class model, an operation or method is defined to be side effect free if the isQuery attribute of the operations is true. For the purpose of this document, we will refer to attributes, association-ends, and side effect free methods and operations as being properties. A property is one of:

- an Attribute
- an AssociationEnd
- an Operation with isQuery being true
- a Method with isQuery being true
The value of a property on an object that is defined in a class diagram is specified in an OCL expression by a dot followed by the name of the property. For example:

```ocl
context Person inv:
    self.isMarried
```

If `self` is a reference to an object, then `self.property` is the value of the `property` property on `self`.

### 7.6.1 Properties: Attributes

For example, the age of a Person is written as `self.age`:

```ocl
context Person inv:
    self.age > 0
```

The value of the subexpression `self.age` is the value of the `age` attribute on the particular instance of Person identified by `self`. The type of this subexpression is the type of the attribute `age`, which is the standard type `Integer`.

Using attributes and operations defined on the basic value types, we can express calculations etc. over the class model. For example, a business rule might be “the age of a Person is always greater than zero.” This can be stated by the invariant above.

Attributes may have multiplicities in a UML model. Whenever the multiplicity of an attribute is greater than 1, the result type is collection of values. Collections in OCL are described later in this clause.

### 7.6.2 Properties: Operations

Operations may have parameters. For example, as shown earlier, a Person object has an income expressed as a function of the date. This operation would be accessed as follows, for a Person `aPerson` and a date `aDate`:

```ocl
aPerson.income(aDate)
```

The result of this operation call is a value of the return type of the operation, which is `Integer` in this example. If the operation has out or in/out parameters, the result of this operation is a tuple containing all out, in/out parameters and the return value. For example, if the income operation would have an out parameter `bonus`, the result of the above operation call is of type `Tuple( bonus: Integer, result: Integer)`. You can access these values using the names of the out parameters, and the keyword `result`. For example:

```ocl
aPerson.income(aDate).bonus = 300 and
aPerson.income(aDate).result = 5000
```

Note that the out parameters need not be included in the operation call. Values for all in or in/out parameters are necessary.

#### Defining operations

The operation itself could be defined by a postcondition constraint. This is a constraint that is stereotyped as «postcondition». The object that is returned by the operation can be referred to by `result`. It takes the following form:

```ocl
context Person::income (d: Date) : Integer
    post: result = age * 1000
```

The right-hand-side of this definition may refer to the operation being defined (i.e., the definition may be recursive) as long as the recursion is not infinite. Inside a pre- or postcondition one can also use the parameters of the operation. The type of `result`, when the operation has no out or in/out parameters, is the return type of the operation, which is `Integer` in the above example. When the operation does have out or in/out parameters, the return type is a `Tuple` as explained above. The postcondition for the income operation with out parameter `bonus` may take the following form:
7.6.3 Properties: AssociationEnds and Navigation

Starting from a specific object, we can navigate an association on the class diagram to refer to other objects and their properties. To do so, we navigate the association by using the opposite association-end:

```
object.associationEndName
```

The value of this expression is the set of objects on the other side of the `associationEndName` association. If the multiplicity of the association-end has a maximum of one (“0..1” or “1”), then the value of this expression is an object. In the example class diagram, when we start in the context of a Company (i.e., `self` is an instance of Company), we can write:

```
context Company
inv: self.manager.isUnemployed = false
inv: self.employee->notEmpty()
```

In the first invariant `self.manager` is a Person, because the multiplicity of the association is one. In the second invariant `self.employee` will evaluate in a Set of Persons. By default, navigation will result in a Set. When the association on the Class Diagram is adorned with `{ordered}`, the navigation results in an OrderedSet.

Collections, like Sets, OrderedSets, Bags, and Sequences are predefined types in OCL. They have a large number of predefined operations on them. A property of the collection itself is accessed by using an arrow ‘->’ followed by the name of the property. The following example is in the context of a person:

```
context Person
inv: self.employer->size() < 3
```

This applies the `size` property on the Set `self.employer`, which results in the number of employers of the Person `self`.

```
context Person
inv: self.employer->isEmpty()
```

This applies the `isEmpty` property on the Set `self.employer`. This evaluates to true if the set of employers is empty and false otherwise.

**Missing Association names**

The association name is never missing. If no explicit name is available, an implicit name is constructed in accordance with the UML style guide. Associations that are not explicitly named, are given names that are constructed according to the following production rule:

```
“A” <association-end-name1> “_” <association-end-name2>
```

where `<association-end-name1>` is the name of one association end and lexically precedes `<association-end-name2>` which is the name of the other association end.
Missing Association End names

The name of an association-end is never missing. If no explicit name is available an implicit name is taken from the name of the class to which the end is attached.

**NOTE:** To tool vendors: this is a non-normative change from OCL 2.2, where the UML style guidance of converting the first letter of the implicit name to lowercase was endorsed. The normative text has never defined how implicit names are obtained. Tool vendors may wish to provide backward/forward compatibility warnings for this change.

![Figure 7.2 - Ambiguous name example](image)

This may result in an ambiguity between an implicit association end name and another explicit name, unless only one of the association ends is navigable. The ambiguous name cannot be used in OCL.

```
aPerson.role   -- ambiguous
```

Qualifying association ends with association names

An association end name may be qualified with its association name or its source classifier name to resolve an ambiguity.

```
aPerson.Person::role                           -- still ambiguous
aPerson.A_person_role::role                    -- some Parts, using implicit Person to Part association name
aPerson.A_owner_role::role                     -- a Role, using implicit Person to Role association name
```

Ends owned by associations

In a UML association, an end may be owned by the Classifier at that end, or by the association, itself. The ownership of the end is not significant to OCL. In either case, the association end is considered as a property of the Classifier and can be navigated from that end to the other.

Navigation over Associations with Multiplicity Zero or One

Because the multiplicity of the role manager is one, `self.manager` is an object of type Person. Such a single object can be used as a Set as well. It then behaves as if it is a Set containing the single object. The usage as a set is done through the arrow followed by a property of Set. This is shown in the following example:

```
context Company inv:
    self.manager->size() = 1
```

The sub-expression `self.manager` is used as a Set, because the arrow is used to access the `size` property on Set. This expression evaluates to true.

```
context Company inv:
    self.manager->foo
```

The sub-expression `self.manager` is used as Set, because the arrow is used to access the `foo` property on the Set. This expression is incorrect, because `foo` is not a defined property of Set.

```
context Company inv:
    self.manager.age > 40
```

The sub-expression `self.manager` is used as a Person, because the dot is used to access the `age` property of Person.
In the case of an optional (0..1 multiplicity) association, this is especially useful to check whether there is an object or not when navigating the association. In the example we can write:

```oclm
context Person inv:
    self.wife->notEmpty() implies self.wife.gender = Gender::female
```

### Combining Properties

Properties can be combined to make more complicated expressions. An important rule is that an OCL expression always evaluates to a specific object of a specific type. After obtaining a result, one can always apply another property to the result to get a new result value. Therefore, each OCL expression can be read and evaluated left-to-right.

Following are some invariants that use combined properties on the example class diagram:

1. Married people are of age $\geq 18$

   ```oclm
   context Person inv:
   self.wife->notEmpty() implies self.wife.age $\geq$ 18 and
   self.husband->notEmpty() implies self.husband.age $\geq$ 18
   ```

2. A company has at most 50 employees

   ```oclm
   context Company inv:
   self.employee->size() <= 50
   ```

### 7.6.4 Navigation to Association Classes

To specify navigation to association classes (Job and Marriage in the example), OCL uses a dot and the name of the association class:

```oclm
context Person inv:
    self.Job
```

The sub-expression `self.Job` evaluates to a Set of all the jobs a person has with the companies that are his/her employer. In the case of an association class, there is no explicit rolename in the class diagram. The name `Job` used in this navigation is the name of the association class.

In case of a recursive association, that is an association of a class with itself, the name of the association class alone is not enough. We need to distinguish the direction in which the association is navigated as well as the name of the association class. Take the following model as an example.

![Figure 7.3 - Navigating recursive association classes](image)

When navigating to an association class such as `EmployeeRanking` there are two possibilities depending on the direction. For instance, in the above example, we may navigate towards the `employees` end, or the `bosses` end. By using the name of the association class alone, these two options cannot be distinguished. To make the distinction, the rolename of the direction in which we want to navigate is added to the association class name, enclosed in square brackets. In the expression
**context** Person inv:
   self.EmployeeRanking[bosses]->sum() > 0

the *self.EmployeeRanking[bosses]* evaluates to the set of *EmployeeRankings* belonging to the collection of *bosses*. And in the expression

**context** Person inv:
   self.EmployeeRanking[employees]->sum() > 0

the *self.EmployeeRanking[employees]* evaluates to the set of *EmployeeRankings* belonging to the collection of *employees*. The unqualified use of the association class name is not allowed in such a recursive situation. Thus, the following example is invalid:

**context** Person inv:
   self.EmployeeRanking->sum() > 0 -- INVALID!

In a non-recursive situation, the association class name alone is enough, although the qualified version is allowed as well. Therefore, the examples at the start of this sub clause could also be written as:

**context** Person inv:
   self.Job[employer]

### 7.6.5 Navigation from Association Classes

We can navigate from the association class itself to the objects that participate in the association. This is done using the dot-notation and the role-names at the association-ends.

**context** Job
   **inv**: self.employer.numberOfEmployees >= 1
   **inv**: self.employee.age > 21

Navigation from an association class to one of the objects on the association will always deliver exactly one object. This is a result of the definition of AssociationClass. Therefore, the result of this navigation is exactly one object, although it can be used as a Set using the arrow (->).

### 7.6.6 Navigation through Qualified Associations

Qualified associations use one or more qualifier attributes to select the objects at the other end of the association. To navigate them, we can add the values for the qualifiers to the navigation. This is done using square brackets, following the role-name. It is permissible to leave out the qualifier values, in which case the result will be all objects at the other end of the association. The following example results in a Set(Person) containing all customers of the Bank.

**context** Bank inv:
   self.customer

The next example results in one Person, having account number 8764423.

**context** Bank inv:
   self.customer[8764423]

If there is more than one qualifier attribute, the values are separated by commas, in the order which is specified in the UML class model. It is not permissible to partially specify the qualifier attribute values.

### 7.6.7 Using Pathnames for Packages

Within UML, types are organized in packages. OCL provides a way of explicitly referring to types in other packages by using a package-pathname prefix. The syntax is a package name, followed by a double colon:
This usage of pathnames is transitive and can also be used for packages within packages:

Packagename1::Packagename2::Typename

### 7.6.8 Accessing overridden properties of supertypes

Whenever properties are redefined within a type, the property of the supertypes can be accessed using the `oclAsType()` operation. Whenever we have a class B as a subtype of class A, and a property p1 of both A and B, we can write:

```
context B inv:
  self.oclAsType(A).p1 -- accesses the p1 property defined in A
  self.p1 -- accesses the p1 property defined in B
```

Figure 7.4 shows an example where such a construct is needed. In this model fragment there is an ambiguity with the OCL expression on Dependency:

```
context Dependency inv:
  self.source <> self
```

This can either mean normal association navigation, which is inherited from ModelElement, or it might also mean navigation through the dotted line as an association class. Both possible navigations use the same role-name, so this is always ambiguous. Using `oclAsType()` we can distinguish between them with:

```
context Dependency
  inv: self.oclAsType(Dependency).source->isEmpty()
  inv: self.oclAsType(ModelElement).source->isEmpty()
```

![Diagram of Dependency](image)

**Figure 7.4 - Accessing Overridden Properties Example**

### 7.6.9 Predefined properties on All Objects

There are several properties that apply to all objects, and are predefined in OCL. These are:

- `oclIsTypeOf(t : Classifier) : Boolean`
- `oclIsKindOf(t : Classifier) : Boolean`
- `oclInState(s : OclState) : Boolean`
- `oclIsNew() : Boolean`
- `oclAsType(t : Classifier) : instance of Classifier`
The operation is `oclIsTypeOf` results in true if the type of self and t are the same. For example:

```ocl
context Person
inv: self.oclIsTypeOf(Person) -- is true
inv: self.oclIsTypeOf(Company) -- is false
```

The above property deals with the direct type of an object. The `oclIsKindOf` property determines whether `t` is either the direct type or one of the supertypes of an object.

The operation `oclInState(s)` results in true if the object is in the state `s`. Possible states for the operation `oclInState(s)` are all states of the statemachine that defines the classifier's behavior. For nested states the statenames can be combined using the double colon `"::"`.

![Figure 7.5 - Statemachine Example](image)

In the example statemachine above, values for `s` can be `On`, `Off::Standby`, `Off::NoPower`. If the classifier of `object` has the above associated statemachine, valid OCL expressions are:

```ocl
object.oclInState(On)
octect object.oclInState(Off)
octect object.oclInState(Off::Standby)
octect object.oclInState(Off::NoPower)
```

If there are multiple statemachines attached to the object’s classifier, then the statename can be prefixed with the name of the statemachine containing the state and the double colon `"::"` as with nested states.

The operation `oclIsNew` evaluates to true if, used in a postcondition, the object is created during performing the operation (i.e., it didn’t exist at precondition time).

### 7.6.10 Features on Classes Themselves

All properties discussed until now in OCL are properties on instances of classes. The types are either predefined in OCL or defined in the class model. In OCL, it is also possible to use static features, applicable to the types/classes themselves rather than to their instances. For example, the Employee class may define a static operation “uniqueID” that computes a unique ID to use in the initialization of the employee ID attribute:

```ocl
context Employee::id : String
init:
  Employee::uniqueID()
```

Static features are invoked using the `"::"` operator and are distinct from the features of the Classifier metaclass, which include the allInstances operation pre-defined by OCL. If we want to make sure that all instances of Person have unique names, we can write:

```ocl
context Person inv:
  Person.allInstances()->forAll(p1, p2 |
    p1 <> p2 implies p1.name <> p2.name)
```
Invocation of \textit{allInstances} uses the `.' operator rather than `::' because it is not a static operation. It is an operation applicable to instances of the Classifier metaclass, of which Person is an example.

### 7.6.11 Collections

Single navigation of an association results in a Set, combined navigations in a Bag, and navigation over associations adorned with \{ordered\} results in an OrderedSet. Therefore, the collection types defined in the OCL Standard Library play an important role in OCL expressions.

The type \textit{Collection} is predefined in OCL. The Collection type defines a large number of predefined operations to enable the OCL expression author (the modeler) to manipulate collections. Consistent with the definition of OCL as an expression language, collection operations never change collections; \textit{isQuery} is always true. They may result in a collection, but rather than changing the original collection they project the result into a new one.

Collection is an abstract type, with the concrete collection types as its subtypes. OCL distinguishes three different collection types: Set, Sequence, and Bag. A Set is the mathematical set. It does not contain duplicate elements. A Bag is like a set, which may contain duplicates (i.e., the same element may be in a bag twice or more). A Sequence is like a Bag in which the elements are ordered. Both Bags and Sets have no order defined on them.

#### Collection Literals

Sets, Sequences, and Bags can be specified by a literal in OCL. Curly brackets surround the elements of the collection, elements in the collection are written within, separated by commas. The type of the collection is written before the curly brackets:

- Set \{1, 2, 5, 88\}
- Set \{'apple,' orange,'strawberry'\}

A Sequence:

- Sequence \{1, 3, 45, 2, 3\}
- Sequence \{'ape,'nut'\}

A Bag:

- Bag \{1, 3, 4, 3, 5\}

Because of the usefulness of a Sequence of consecutive Integers, there is a separate literal to create them. The elements inside the curly brackets can be replaced by an interval specification, which consists of two expressions of type Integer, \textit{Int-expr1} and \textit{Int-expr2}, separated by `..'. This denotes all the Integers between the values of \textit{Int-expr1} and \textit{Int-expr2}, including the values of \textit{Int-expr1} and \textit{Int-expr2} themselves:

- Sequence \{1..(6 + 4)\}
- Sequence \{1..10\}

-- are both identical to
- Sequence \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}

The complete list of Collection operations is described in Clause 11 (“The OCL Standard Library”).

Collections can be specified by a literal, as described above. The only other way to get a collection is by navigation. To be more precise, the only way to get a Set, OrderedSet, Sequence, or Bag is:
1. a literal, this will result in a Set, OrderedSet, Sequence, or Bag:
   - Set \{2, 4, 1, 5, 7, 13, 11, 17\}
   - OrderedSet \{1, 2, 3, 5, 7, 11, 13, 17\}
   - Sequence \{1, 2, 3, 5, 7, 11, 13, 17\}
   - Bag \{1, 2, 3, 2, 1\}

2. a navigation starting from a single object can result in a collection:
   - context Company inv:
     self.employee

3. operations on collections may result in new collections:
   - collection1->union(collection2)

### 7.6.12 Collections of Collections

OCL allows elements of collections to be collections themselves. The OCL Standard Library includes specific flattened operations for collections. These can be used to flatten collections of collections explicitly.

### 7.6.13 Collection Type Hierarchy and Type Conformance Rules

In addition to the type conformance rules in 7.5.5, ‘Type Conformance’ the following rules hold for all types, including the collection types:

- The types Set (X), Bag (X), and Sequence (X) are all subtypes of Collection (X).

Type conformance rules are as follows for the collection types:

- \textit{Type1} conforms to \textit{Type2} when they are identical (standard rule for all types).
- \textit{Type1} conforms to \textit{Type2} when it is a subtype of \textit{Type2} (standard rule for all types).
- \textit{Collection(Type1)} conforms to \textit{Collection(Type2)}, when \textit{Type1} conforms to \textit{Type2}. This is also true for \textit{Set(Type1)/Set(Type2), Sequence(Type1)/Sequence(Type2), Bag(Type1)/Bag(Type2)}.
- Type conformance is transitive: if \textit{Type1} conforms to \textit{Type2}, and \textit{Type2} conforms to \textit{Type3}, then \textit{Type1} conforms to \textit{Type3} (standard rule for all types).

For example, if \textit{Bicycle} and \textit{Car} are two separate subtypes of \textit{Transport}:

- Set(Bicycle) conforms to Set(Transport)
- Set(Bicycle) conforms to Collection(Bicycle)
- Set(Bicycle) conforms to Collection(Transport)

Note that Set(Bicycle) does not conform to Bag(Bicycle), nor the other way around. They are both subtypes of Collection(Bicycle) at the same level in the hierarchy.

### 7.6.14 Previous Values in Postconditions

As stated in 7.4.4, ‘Pre- and Postconditions’ OCL can be used to specify pre- and postconditions on operations and behaviors in UML. In a postcondition, the expression can refer to values of any feature of an object at two moments in time:
• the value of a feature at the start of the operation or behavior
• the value of a feature upon completion of the operation or behavior

The value of an operation call or a property navigation in a postcondition is the value upon completion of the operation. To refer to the value of a feature at the start of the operation, one has to postfix the property name with the keyword `@pre`:

```
context Person::birthdayHappens()
post: age = age@pre + 1
```

The property `age` refers to the property of the instance of `Person` that executes the operation. The property `age@pre` refers to the value of the property `age` of the `Person` that executes the operation, at the start of the operation.

In the case of an operation call, the `@pre` is postfixed to the operation name, before the parameters.

```
context Company::hireEmployee(p : Person)
post: employees = employees@pre->including(p) and
      stockprice() = stockprice@pre() + 10
```

When the pre-value of a feature evaluates to an object, all further properties that are accessed of this object are the new values (upon completion of the operation) of this object. So:

```
a.b@pre.c -- takes the old value of property b of a, say x
    -- and then the new value of c of x.
```

```
a.b@pre.c@pre-- takes the old value of property b of a, say x
    -- and then the old value of c of x.
```

The `@pre` postfix is allowed only in OCL expressions that are part of a Postcondition, and only on invocations of the features of model classifiers. Asking for a current property of an object that has been destroyed during execution of the operation results in null. Also, referring to the previous value of an object that has been created during execution of the operation results in null.

### 7.6.15 Tuples

It is possible to compose several values into a *tuple*. A tuple consists of named parts, each of which can have a distinct type. Some examples of tuples are:

```
Tuple {name: String = 'John,' age: Integer = 10}
Tuple {a: Collection(Integer) = Set{1, 3, 4}, b: String = 'foo,' c: String = 'bar'}
```

This is also the way to write tuple literals in OCL; they are enclosed in curly brackets, and the parts are separated by commas. The type names are optional, and the order of the parts is unimportant. Thus:

```
Tuple {name: String = 'John,' age: Integer = 10} is equivalent to
Tuple {name = 'John,' age = 10} and to
Tuple {age = 10, name = 'John'}
```

Also, note that the values of the parts may be given by arbitrary OCL expressions, so for example we may write:

```
context Person def:
attr statistics : Set(TupleType(company: Company, numEmployees: Integer,
    wellpaidEmployees: Set(Person), totalSalary: Integer)) =
    managedCompanies->collect(c |
    Tuple { company: Company = c,
        numEmployees: Integer = c.employee->size(),
        wellpaidEmployees: Set(Person) = c.Job->select(salary>10000).employee->asSet(),
```
totalSalary: Integer = c.Job.salary->sum()
}
}

This results in a bag of tuples summarizing the company, number of employees, the best paid employees, and total salary costs of each company a person manages.

The parts of a tuple are accessed by their names, using the same dot notation that is used for accessing attributes. Thus:

```
Tuple {x: Integer = 5, y: String = 'hi'}.x = 5
```

is a true, if somewhat pointless, expression. Using the definition of statistics above, we can write:

```
context Person inv:
  statistics->sortedBy(totalSalary)->last().wellpaidEmployees->includes(self)
```

This asserts that a person is one of the best-paid employees of the company with the highest total salary that he manages. In this expression, both ‘totalSalary’ and ‘wellpaidEmployees’ are accessing tuple parts.

### 7.7 Collection Operations

OCL defines many operations on the collection types. These operations are specifically meant to enable a flexible and powerful way of projecting new collections from existing ones. The different constructs are described in the following subclauses.

#### 7.7.1 Select and Reject Operations

Sometimes an expression using operations and navigations results in a collection, while we are interested only in a special subset of the collection. OCL has special constructs to specify a selection from a specific collection. These are the `select` and `reject` operations. The select specifies a subset of a collection. A select is an operation on a collection and is specified using the arrow-syntax:

```
collection->select( ... )
```

The parameter of select has a special syntax that enables one to specify which elements of the collection we want to select. There are three different forms, of which the simplest one is:

```
collection->select( boolean-expression )
```

This results in a collection that contains all the elements from `collection` for which the `boolean-expression` evaluates to true. To find the result of this expression, for each element in `collection` the expression `boolean-expression` is evaluated. If this evaluates to true, the element is included in the result collection, otherwise not. As an example, the following OCL expression specifies that the collection of all the employees older than 50 years is not empty:

```
context Company inv:
self.employee->select(age > 50)->notEmpty()
```

The `self.employee` is of type `Set(Person)`. The `select` takes each person from `self.employee` and evaluates `age > 50` for this person. If this results in `true`, then the person is in the result Set.

As shown in the previous example, the context for the expression in the select argument is the element of the collection on which the select is invoked. Thus the `age` property is taken in the context of a person.

In the above example, it is impossible to refer explicitly to the persons themselves; you can only refer to properties of them. To enable to refer to the persons themselves, there is a more general syntax for the select expression:

```
collection->select( v | boolean-expression-with-v )
```
The variable $v$ is called the iterator. When the select is evaluated, $v$ iterates over the collection and the boolean-expression-with-$v$ is evaluated for each $v$. The $v$ is a reference to the object from the collection and can be used to refer to the objects themselves from the collection. The two examples below are identical:

```ocl
class Company
context Company inv:
    self.employee->select(age > 50)->notEmpty()
context Company inv:
    self.employee->select(p | p.age > 50)->notEmpty()
```

The result of the complete select is the collection of persons $p$ for which the $p.age > 50$ evaluates to True. This amounts to a subset of self.employee.

As a final extension to the select syntax, the expected type of the variable $v$ can be given. The select now is written as:

```ocl
collection->select( v : Type | boolean-expression-with-v )
```

The meaning of this is that the objects in collection must be of type $Type$. The next example is identical to the previous examples:

```ocl
class Company
context Company inv:
    self.employee.select(p : Person | p.age > 50)->notEmpty()
```

As an example, specify that the collection of all the employees who are not married is empty:

```ocl
collection->reject( isMarried )->isEmpty()
```

As an example, specify that the collection of all the employees who are not married is empty:

```ocl
collection->reject( isMarried )->isEmpty()
```

As shown in the previous sub clause, the select and reject operations always result in a sub-collection of the original collection. When we want to specify a collection that is derived from some other collection, but which contains different objects from the original collection (i.e., it is not a sub-collection), we can use a collect operation. The collect operation uses the same syntax as the select and reject and is written as one of:

```ocl
collection->collect( v : Type | expression-with-v )
collection->collect( v | expression-with-v )
collection->collect( boolean-expression )
```

The value of the reject operation is the collection of the results of all the evaluations of expression-with-v.
An example: specify the collection of birthDates for all employees in the context of a company. This can be written in the context of a Company object as one of:

- `self.employee->collect( birthDate )`
- `self.employee->collect( person | person.birthDate )`
- `self.employee->collect( person : Person | person.birthDate )`

An important issue here is that when the source collection is a Set the resulting collection is not a Set but a Bag. Moreover, if the source collection is a Sequence or an OrderedSet, the resulting collection is a Sequence. When more than one employee has the same value for birthDate, this value will be an element of the resulting Bag more than once. The Bag resulting from the collect operation always has the same size as the original collection.

It is possible to make a Set from the Bag, by using the asSet property on the Bag. The following expression results in the Set of different birthDates from all employees of a Company:

- `self.employee->collect( birthDate )->asSet()`

**Shorthand for Collect**

Because navigation through many objects is very common, there is a shorthand notation for the collect that makes the OCL expressions more readable. Instead of

- `self.employee->collect(birthdate)`

we can also write:

- `self.employee.birthdate`

In general, when we apply a property to a collection of Objects, then it will automatically be interpreted as a collect over the members of the collection with the specified property.

For any `propertyname` that is defined as a property on the objects in a collection, the following two expressions are identical:

- `collection.propertyname`
- `collection->collect(propertyname)`

and so are these if the property is parameterized:

- `collection.propertyname (par1, par2, ...)`
- `collection->collect (propertyname(par1, par2, ...))`

### 7.7.3 ForAll Operation

Many times a constraint is needed on all elements of a collection. The forAll operation in OCL allows specifying a Boolean expression, which must hold for all objects in a collection:

- `collection->forAll( v : Type | boolean-expression-with-v )`
- `collection->forAll( v | boolean-expression-with-v )`
- `collection->forAll( boolean-expression )`

This forAll expression results in a Boolean. The result is true if the boolean-expression-with-v is true for all elements of collection. If the boolean-expression-with-v is false for one or more v in collection, then the complete expression evaluates to false. For example, in the context of a company:

- `context Company`
- `inv: self.employee->forAll( age <= 65 )`
- `inv: self.employee->forAll( p | p.age <= 65 )`
- `inv: self.employee->forAll( p : Person | p.age <= 65 )`
These invariants evaluate to true if the age property of each employee is less or equal to 65.

The forAll operation has an extended variant in which more than one iterator is used. Both iterators will iterate over the complete collection. Effectively this is a forAll on the Cartesian product of the collection with itself.

```ocl
class Company inv:
  self.employee->forAll( e1, e2 : Person |
    e1 <> e2 implies e1.forename <> e2.forename)
```

This expression evaluates to true if the forenames of all employees are different. It is semantically equivalent to:

```ocl
class Company inv:
  self.employee->forAll (e1 | self.employee->forAll (e2 |
    e1 <> e2 implies e1.forename <> e2.forename))
```

### 7.7.4 Exists Operation

Many times one needs to know whether there is at least one element in a collection for which a constraint holds. The exists operation in OCL allows you to specify a Boolean expression that must hold for at least one object in a collection:

```ocl
collection->exists( v : Type | boolean-expression-with-v )
collection->exists( v | boolean-expression-with-v )
collection->exists( boolean-expression )
```

This exists operation results in a Boolean. The result is true if the boolean-expression-with-v is true for at least one element of collection. If the boolean-expression-with-v is false for all v in collection, then the complete expression evaluates to false. For example, in the context of a company:

```ocl
class Company inv:
  self.employee->exists( forename = 'Jack' )
class Company inv:
  self.employee->exists( p | p.forename = 'Jack' )
class Company inv:
  self.employee->exists( p : Person | p.forename = 'Jack' )
```

These expressions evaluate to true if the forename property of at least one employee is equal to ‘Jack.’

Similarly to forAll expression an exists expression may declare multiple iterators.

### 7.7.5 Closure Operation

The iterators described in the preceding sections return results from the elements of a collection. The closure supports returning results from the elements of a collection, the elements of the elements of a collection, the elements of the elements of the elements of a collection, and so forth. This can be useful for iterating over a transitive relationship such as a UML generalization. closure operation uses the same syntax as the select and reject iterators and is written as one of

```ocl
source>closure( v : Type | expression-with-v )
source>closure( v | expression-with-v )
source>closure( expression )
```

The returned collection of the closure iteration is an accumulation of the source, and the collections resulting from the recursive invocation of expression-with-v in which v is associated exactly once with each distinct element of the returned collection. The iteration terminates when expression-with-v returns empty collections or collections containing only already accumulated elements. The collection type of the result collection is the unique form (Set or OrderedSet) of the original source collection. If the source collection is ordered, the result is in depth first preorder. The result satisfies the postcondition:
post: let sourceAndResult : Set(Type) = source->asSet()->union(result) in
sourceAndResult = sourceAndResult->collect(expression)

For a simple parent-children relationship and known parents
parents->closure(children)
computes the set of parents.children, parents.children.children, parents.children.children.children etc.

In the opposite direction
self->asOrderedSet()->closure(mother)
computes the maternal line.

For a more complex relationship such as UML Classifier generalization
aClassifier.generalization()->closure(general.generalization).general()->including(aClassifier)
computes the set comprising aClassifier and all its generalizations. The closure recurses over the Generalizations to compute the transitive set of all Generalizations. The generalized classifier is collected from each of these before including the originating aClassifier in the result.

As with all other iterators, self remains unchanged throughout the recursion, and an implicit source attempts to resolve features against iterators.

7.7.6 Iterate Operation

The iterate operation is slightly more complicated, but is very generic. The operations reject, select, forAll, exists, collect can all be described in terms of iterate. An accumulation builds one value by iterating over a collection.

collection->iterate( elem : Type; acc : Type = <expression> | expression-with-elem-and-acc )

The variable elem is the iterator, as in the definition of select, forAll, etc. The variable acc is the accumulator. The accumulator gets an initial value <expression>. When the iterate is evaluated, elem iterates over the collection and the expression-with-elem-and-acc is evaluated for each elem. After each evaluation of expression-with-elem-and-acc, its value is assigned to acc. In this way, the value of acc is built up during the iteration of the collection. The collect operation described in terms of iterate will look like:

collection->collect(x : T | x.property)
-- is identical to:
collection->iterate(x : T; acc : T2 = Bag{} | acc->including(x.property))

Or written in Java-like pseudocode the result of the iterate can be calculated as:

iterate(elem : T; acc : T2 = value)
{
    acc = value;
    for(Enumeration e = collection.elements() ; e.hasMoreElements(); ){
        elem = e.nextElement();
        acc.add(<expression-with-elem-and-acc>
    }
    return acc;
}
Although the Java pseudo code uses a ‘next element,’ the iterate operation is defined not only for Sequence, but for each collection type. The order of the iteration through the elements in the collection is not defined for Set and Bag. For a Sequence the order is the order of the elements in the sequence.

7.8 Messages in OCL

This sub clause contains some examples of the concrete syntax and explains the finer details of the message expression. In earlier versions the phrase “actions in OCL” was used, but message was found to capture the meaning more precisely.

7.8.1 Calling operations and sending signals

To specify that communication has taken place, the hasSent (‘^’) operator is used:

```ocl
class OCLPackage

context Subject::hasChanged()
post: observer^update(12, 14)
```

The `observer^update(12, 14)` results in true if an update message with arguments 12 and 14 was sent to `observer` during the execution of the operation. `Update()` is either an Operation that is defined in the class of `observer`, or it is a Signal specified in the UML model. The argument(s) of the message expression (12 and 14 in this example) must conform to the parameters of the operation/signal definition.

If the actual arguments of the operation/signal are not known, or not restricted in any way, it can be left unspecified. This is shown by using a question mark. Following the question mark is an optional type, which may be needed to find the correct operation when the same operation exists with different parameter types.

```ocl
class OCLPackage

context Subject::hasChanged()
```

This example states that the message update has been sent to `observer`, but that the values of the parameters are not known.

OCL also defines a special `OclMessage` type. One can get the actual OclMessages through the message operator: `^^`.

```ocl
class OCLPackage

context Subject::hasChanged()
post: observer^^update(12, 14)
```

This results in the Sequence of messages sent. Each element of the collection is an instance of `OclMessage`. In the remainder of the constraint one can refer to the parameters of the operation using their formal parameter name from the operation definition. If the operation update has been defined with formal parameters named `i` and `j`, then we can write:

```ocl
class OCLPackage

context Subject::hasChanged()
post: let messages : Sequence(OclMessage) = observer^^update(? : Integer, ? : Integer) in
  messages->notEmpty() and
  messages->exists( m | m.i > 0 and m.j >= m.i )
```

The value of the parameter `i` is not known, but it must be greater than zero and the value of parameter `j` must be larger or equal to `i`.

Because the `^^` operator results in an instance of `OclMessage`, the message expression can also be used to specify collections of messages sent to different targets. For an observer pattern we can write:

```ocl
class OCLPackage

context Subject::hasChanged()
post: let messages : Sequence(OclMessage) = observers->collect(o | o^^update(? : Integer, ? : Integer)) in
  messages->forAll(m | m.i <= m.j )
```
Messages is now a set of OclMessage instances, where every OclMessage instance has one of the observers as a target.

7.8.2 Accessing result values

A signal sent message is by definition asynchronous, so there never is a return value. If there is a logical return value it must be modeled as a separate signal message. Yet, for an operation call there is a potential return value. This is only available if the operation has already returned (not necessary if the operation call is asynchronous), and it specifies a return type in its definition. The standard operation \texttt{result()} of OclMessage contains the return value of the called operation. If \texttt{getMoney(...)} is an operation on Company that returns a boolean, as in \texttt{Company::getMoney(amount : Integer) : Boolean}, we can write:

```ocl
context Person::giveSalary(amount : Integer)
post: let message : OclMessage = company^getMoney(amount) in
  message.hasReturned() = true
  message.result() = true
```

As with the previous example we can also access a collection of return values from a collection of OclMessages. If \texttt{message.hasReturned()} is false, then \texttt{message.result()} will be invalid.

7.8.3 An example

This sub clause shows an example of using the OCL message expression.

The Example and Problem

Suppose we have built a component, which takes any form of input and transforms it into garbage (aka encrypts it). The component \texttt{GarbageCan} uses an interface \texttt{UsefulInformationProvider} that must be implemented by users of the component to provide the input. The operation \texttt{getNextPieceOfGarbage} of \texttt{GarbageCan} can then be used to retrieve the garbled data. Figure 7.6 shows the component's class diagram. Note that none of the operations are marked as queries.

![Figure 7.6 - OclMessageExample](image)

When selling the component, we do not want to give the source code to our customers. However, we want to specify the component's behavior as precisely as possible. So, for example, we want to specify, what \texttt{getNextPieceOfGarbage} does. Note that we cannot write:

```ocl
context GarbageCan::getNextPieceOfGarbage() : Integer
post: result = (datasource.getNextPieceOfData() * .7683425 + 10000) / 20 + 3
```

© ISO/IEC 2012 - All rights reserved
because `UsefulInformationProvider::getNextPieceOfData()` is not a query (e.g., it may increase some internal pointer so that it can return the next piece of data at the next call). Still we would like to say something about how the garbage is derived from the original data.

**The solution**

To solve this problem, we can use an OclMessage to represent the call to `getNextPieceOfData`. This allows us to check for the result. Note that we need to demand that the call has returned before accessing the result:

```asciidoc
context GarbageCan::getNextPieceOfGarbage() : Integer
post: let message : OclMessage = datasource^^getNextPieceOfData()^first() in
    message.hasReturned()
    and
    result = (message.result() * .7683425 + 10000) / 20 + 3
```

### 7.9 Resolving Properties

For any property (attribute, operation, or navigation) the full notation includes the object of which the property is taken. As seen in 7.4.3, `Invariants` `self` can be left implicit, and so can the iterator variables in collection operations. At any place in an expression, when an iterator is left out, an implicit iterator-variable is introduced. For example in:

```asciidoc
class Person inv:
    employer->forAll( employee->exists( lastName = name) )
```

three implicit variables are introduced. The first is `self`, which is always the instance from which the constraint starts. Secondly an implicit iterator is introduced by the `forAll` and third by the `exists`. The implicit iterator variables are unnamed. The properties `employer`, `employee`, `lastName`, and `name` all have the object on which they are applied left out. Resolving these goes as follows:

- at the place of `employer` there is one implicit variable: `self : Person`. Therefore `employer` must be a property of `self`.
- at the place of `employee` there are two implicit variables: `self : Person` and `iter1 : Company`. Therefore `employer` must be a property of either `self` or `iter1`. If `employee` is a property of both `self` and `iter1`, then it is defined to belong to the variable in the most inner scope, which is `iter1`.
- at the place of `lastName` and `name` there are three implicit variables: `self : Person`, `iter1 : Company` and `iter2 : Person`. Therefore `lastName` and `name` must both be a property of either `self` or `iter1` or `iter2`. In the UML model property `name` is a property of `iter1`. However, `lastName` is a property of both `self` and `iter2`. This is ambiguous and therefore the `lastName` refers to the variable in the most inner scope, which is `iter2`.

Both of the following invariant constraints are correct, but have a different meaning:

```asciidoc
context Person
inv: employer->forAll( employee->exists( p | p.lastName = name ) )
inv: employer->forAll( employee->exists( self.lastName = name ) )
```

A closure iteration may introduce an implicit iterator-variable at each level of recursion and so multiple iterator-variable candidates for consideration as the implicit self. Since all candidates have the same static type, it is only the least deeply nested candidate, with respect to the iteration body, that need be considered as the implicit iterator-variable for a closure.
8 Abstract Syntax

8.1 Introduction

This clause describes the abstract syntax of the OCL. In this abstract syntax a number of metaclasses from the UML metamodel are imported. These metaclasses are shown in the models with a transparent fill color. All metaclasses defined as part of the OCL abstract syntax are shown with a light gray background.

The abstract syntax as described below defines the concepts that are part of the OCL using a MOF compliant metamodel. The abstract syntax is divided into several packages.

- The Types package describes the concepts that define the type system of OCL. It shows which types are predefined in OCL and which types are deduced from the UML models.
- The Expressions package describes the structure of OCL expressions.

8.2 The Types Package

OCL is a typed language. Each expression has a type that is either explicitly declared or can be statically derived. Evaluation of the expression yields a value of this type. Therefore, before we can define expressions, we have to provide a model for the concept of type. A metamodel for OCL types is shown in this sub clause. Note that instances of the classes in the metamodel are the types themselves (e.g., Integer) not instances of the domain they represent (e.g., -15, 0, 2, 3).

The model in Figure 8.1 shows the OCL types. The basic type is the UML Classifier, which includes all subtypes of Classifier from the UML Superstructure.

In the model, the CollectionType (and its subclasses) and the TupleType are special. One can never instantiate all collection types, because there is an infinite number, especially when nested collections are taken into account. Conceptually all these types do exist, but such a type should be (lazily) instantiated by a tool, whenever it is needed in an expression. For convenience an instance representing a collection type or a tuple type may be replicated in different namespaces (such as in a top-level package or within the expression referencing it), however they represent semantically the same type.
Figure 8.1 - Abstract Syntax Kernel Metamodel for OCL Types

**AnyType**

*AnyType* is the metaclass of the special type *OclAny*, which is the type to which all other types conform. *OclAny* is the sole instance of *AnyType*. This metaclass allows defining the special property of being the generalization of all other Classifiers, including Classes, DataTypes, and PrimitiveTypes.

**BagType**

*BagType* is a collection type that describes a multiset of elements where each element may occur multiple times in the bag. The elements are unordered. Part of a *BagType* is the declaration of the type of its elements.

**CollectionType**

*CollectionType* describes a list of elements of a particular given type. *CollectionType* is a concrete metaclass whose instances are the family of abstract Collection(T) data types. Its subclasses are SetType, OrderedSetType, SequenceType, and BagType, whose instances are the concrete Set(T), OrderedSet(T), Sequence(T), and Bag(T), data types, respectively.

Part of every collection type is the declaration of the type of its elements (i.e., a collection type is parameterized with an element type). In the metamodel, this is shown as an association from *CollectionType* to *Classifier*. Note that there is no restriction on the element type of a collection type. This means in particular that a collection type may be parameterized with other collection types allowing collections to be nested arbitrarily deep.

**Associations**

<table>
<thead>
<tr>
<th>elementType</th>
<th>The type of the elements in a collection. All elements in a collection must conform to this type.</th>
</tr>
</thead>
</table>
**InvalidType**

*InvalidType* represents a type that conforms to all types except the VoidType type. The only instance of *InvalidType* is *Invalid*, which is further defined in the standard library. Furthermore *Invalid* has exactly one runtime instance identified as *OclInvalid*.

**MessageType**

*MessageType* describes ocl messages. Similar to the collection types, *MessageType* describes a set of types in the standard library. Part of every *MessageType* is a reference to the declaration of the type of its operation or signal, i.e., an ocl message type is parameterized with an operation or signal. In the metamodel, this is shown as an association from *MessageType* to *Operation* and to *Signal*. *MessageType* is part of the abstract syntax of OCL, residing on M2 level. Its instances, called *OclMessage*, and subtypes of *OclMessage*, reside on M1 level.

**Associations**

- referredSignal The *Signal* that is sent by the message.
- referredOperation The *Operation* that is called by the message.

**OrderedSetType**

*OrderedSetType* is a collection type that describes a set of elements where each distinct element occurs only once in the set. The elements are ordered by their position in the sequence. Part of an *OrderedSetType* is the declaration of the type of its elements.

**SequenceType**

*SequenceType* is a collection type that describes a list of elements where each element may occur multiple times in the sequence. The elements are ordered by their position in the sequence. Part of a *SequenceType* is the declaration of the type of its elements.

**SetType**

*SetType* is a collection type that describes a set of elements where each distinct element occurs only once in the set. The elements are not ordered. Part of a *SetType* is the declaration of the type of its elements.

**TemplateParameterType**

A *TemplateParameterType* is used to refer to generic types in parameterized definitions. It is used in the standard library to represent the parameterized collection operations. A *TemplateParameterType* is usually named “T” (or “T2,” “T3,” and so on, when more than one type parameter is involved).

The *TemplateParameterType* is a sub-class of *Classifier*. 

© ISO/IEC 2012 - All rights reserved
Attributes

specification An un-interpreted opaque definition of the template parameter type.

TupleType

TupleType (informally known as record type or struct) combines different types into a single aggregate type. The parts of a TupleType are described by its attributes, each having a name and a type. There is no restriction on the kind of types that can be used as part of a tuple. In particular, a TupleType may contain other tuple types and collection types. Each attribute of a TupleType represents a single feature of a TupleType. Each part is uniquely identified by its name.

VoidType

VoidType is the metaclass of the OclVoid type that conforms to all types except the OclInvalid type. The only instance of VoidType is OclVoid, which is further defined in the standard library. Furthermore OclVoid has exactly one instance called null - corresponding to the UML NullLiteral literal specification - and representing the absence of value. Note that in contrast with invalid, null is a valid value and as such can be owned by collections.

8.2.1 Type Conformance

The type conformance rules are formally underpinned in the Semantics sub clause of the specification. To ensure that the rules are accessible to UML modelers they are specified in this sub clause using OCL. For this, the additional operation conformsTo(c : Classifier) : Boolean is defined on Classifier. It evaluates to true, if the self Classifier conforms to the argument c. The following OCL statements define type conformance for individual types.

BagType

[3] Different bag types conform to each other if their element types conform to each other.
context BagType
inv: BagType.allInstances()->forAll(b |
  self.elementType.conformsTo(b.elementType) implies self.conformsTo(b))

Classifier

context Classifier
inv: Transitivity: Classifier.allInstances()->forAll(x|Classifier.allInstances()
  ->forAll(y) |
  (self.conformsTo(x) and x.conformsTo(y)) implies self.conformsTo(y))

[5] Classes conform to superclasses and interfaces that they realize.
context Class
inv : self.generalization.general->forAll (p |
  (p.oclsKindOf(Class) or p_oclsKindOf(Interface)) implies
  self.conformsTo(p.oclAsType(Classifier)))

[6] Interfaces conforms to super interfaces.
context Interface
inv : self.generalization.general->forAll (p |
  p_oclsKindOf(Interface) implies self.conformsTo(p.oclAsType(Interface)))
[7] [4] The Conforms operation between Types is reflexive, a Classifier always conform to itself.
   context Classifier
   inv: self.conformsTo(self)

   context Classifier
   inv: Classifier.allInstances()->forAll(t1, t2 |
       (t1.conformsTo(t2) and t2.conformsTo(t1)) implies t1 = t2)

**CollectionType**
[9] [1] Specific collection types conform to collection type.
   context CollectionType
   inv: -- all instances of SetType, SequenceType, BagType conform to a
   -- CollectionType if the elementTypes conform
   CollectionType.allInstances()->forAll (c |
       c.oclIsTypeOf(CollectionType) and
       self.elementType.conformsTo(c.elementType) implies
       self.conformsTo(c))

   context CollectionType
   inv: PrimitiveType.allInstances()->forAll (p | not self.conformsTo(p))

   context CollectionType
   inv: CollectionType.allInstances()->forAll (c |
       (not self.elementType.conformsTo (c.elementType)) implies (not self.conformsTo (c)))

**InvalidType**
[12] [1] OclInvalid conforms to all other types.
   context InvalidType
   inv: Classifier.allInstances()->forAll (c | self.conformsTo (c))

**OrderedSetType**
[13] [1] Different ordered set types conform to each other if their element types conform to each other.
   context OrderedSetType
   inv: OrderedSetType.allInstances()->forAll(s |
       self.elementType.conformsTo(s.elementType) implies self.conformsTo(s))

**PrimitiveType**
[14] [1] Integer conforms to Real.
   context PrimitiveType
   inv: (self.name = 'Integer') implies
       PrimitiveType.allInstances()->forAll (p | (p.name = 'Real') implies
       (self.conformsTo(p)))

   context PrimitiveType
   inv: (self.name = 'UnlimitedNatural') implies
       PrimitiveType.allInstances()->forAll (p | (p.name = 'Integer') implies
       (self.conformsTo(p)))
Note that * is an invalid Integer and so conversion of * to Integer yields invalid whose type conforms to all types.

**SequenceType**

[16][1] Different sequence types conform to each other if their element types conform to each other.

context SequenceType
inv: SequenceType.allInstances()->forAll (s |
    self.elementType.conformsTo(s.elementType) implies self.conformsTo(s))

**SetType**

[17][1] Different set types conform to each other if their element types conform to each other.

context SetType
inv: SetType.allInstances()->forAll (s |
    self.elementType.conformsTo(s.elementType) implies self.conformsTo(s))

**TupleType**

[18][1] Tuple types conform to each other when their names and types conform to each other. Note that allProperties is an additional operation in the UML.

context TupleType
inv: TupleType.allInstances()->forAll (t |
    ( t.allProperties()->forAll (tp |
        -- make sure at least one tuplepart has the same name
        -- (uniqueness of tuplepart names will ensure that not two
        -- tupleparts have the same name within one tuple)
        self.allProperties()->exists(stp|stp.name = tp.name) and
        -- make sure that all tupleparts with the same name conforms.
        self.allProperties()->forAll(stp | (stp.name = tp.name) implies
        stp.type.conformsTo(tp.type))
    )
    implies
    self.conformsTo(t)
)

**VoidType**

[19][1] OclVoid conforms to all other types except OclInvalid.

context VoidType
inv: Classifier.allInstances()->forAll (c | not c.oclIsTypeOf(OclInvalid) implies self.conformsTo (c))

### 8.2.2 Operations and Well-formedness Rules for the Types Package

**BagType**

[20][1] The name of a bag type is “Bag” followed by the element type’s name in parentheses.

context BagType
inv: self.name = ‘Bag(‘ + self.elementType.name + ‘)’

**BooleanType**

allInstances() : Set(Boolean)

Returns Set{true,false}.
**CollectionType**

[21][1] The name of a collection type is “Collection” followed by the element type’s name in parentheses.

```plaintext
class CollectionType
inv: self.name = 'Collection(' + self.elementType.name + ')
```

**InvalidType**

```plaintext
allInstances() : Set(OclInvalid)
```

Returns invalid, since the notional return of Set{invalid} is not well-formed.

**MessageType**

[22][1] MessageType has either a link with a Signal or with an operation, but not both.

```plaintext
class MessageType
inv: referredOperation->size() + referredSignal->size() = 1
```

[23][2] The parameters of the referredOperation become attributes of the instance of MessageType.

```plaintext
class MessageType:
inv: referredOperation->size()=1 implies
Set{1..self.ownedAttribute->size()}-forAll(i | self.ownedAttribute.at(i).cmpSlots(referredOperation.ownedParameter.asProperty()->at(i)))
```

[24][3] The attributes of the referredSignal become attributes of the instance of MessageType.

```plaintext
class MessageType
inv: referredSignal->size() = 1 implies
Set{1..self.ownedAttribute->size()}-forAll(i | self.ownedAttribute.asOrderedSet()->at(i).cmpSlots(referredSignal.ownedAttribute.asOrderedSet()->at(i)))
```

**OrderedSetType**

[25][1] The name of a set type is “OrderedSet” followed by the element type’s name in parentheses.

```plaintext
class OrderedSetType
inv: self.name = 'OrderedSet(' + self.elementType.name + ')
```

**SequenceType**

[26][1] The name of a sequence type is “Sequence” followed by the element type’s name in parentheses.

```plaintext
class SequenceType
inv: self.name = 'Sequence(' + self.elementType.name + ')
```

**SetType**

[27][1] The name of a set type is “Set” followed by the element type’s name in parentheses.

```plaintext
class SetType
inv: self.name = 'Set(' + self.elementType.name + ')
```

**TupleType**

[28][1] The name of a tuple type includes the names of the individual parts and the types of those parts.

```plaintext
class TupleType
inv: name = 'Tuple(' + Sequence{1..allProperties()->size()}-iterate (pn; s: String = '' | let p: Attribute = allProperties() at (pn) in (s.concat (p.name)) + '.')
```
(if (pn>1) then ‘,’ else ‘’ endif).
call (p.name).concat (i:i)
call (p.type.name)
)
)
).
call (i:i)

[29] All parts belonging to a tuple type have unique names.

call TupleType
call inv: -- always true, because attributes must have unique names.

[30] A TupleType instance has only features that are Properties(tuple parts).

call TupleType
call inv: feature->forAll (f | f.oclIsTypeOf(Property))

VoidType

allInstances() : Set(OclVoid)

Returns Set{null}.

8.3 The Expressions Package

This sub clause defines the abstract syntax of the expressions package. This package defines the structure that OCL expressions can have. An overview of the inheritance relationships between all classes defined in this package is shown in Figure 8.2.

Figure 8.2 - The basic structure of the abstract syntax kernel metamodel for Expressions
8.3.1 Expressions Core

Figure 8.2 shows the core part of the Expressions package. The basic structure in the package consists of the classes OclExpression, CallExp, and VariableExp. An OclExpression always has a type, which is usually not explicitly modeled, but derived. Each CallExp has exactly one source, identified by an OclExpression. In this sub clause we use the term ‘property’ that is a generalization of Feature, AssociationEnd, and predefined iterating OCL collection operations.

A FeatureCallExp generalizes all property calls that refer to Features in the UML metamodel. In Figure 8.3 the various subtypes of FeatureCallExp are defined.

Most of the remainder of the expressions package consists of a specification of the different subclasses of CallExp and their specific structure. From the metamodel it can be deduced that an OCL expression always starts with a variable or literal, on which a property is recursively applied.

CallExp

A CallExp is an expression that refers to a feature (operation, property) or to a predefined iterator for collections. Its result value is the evaluation of the corresponding feature. This is an abstract metaclass.

Associations

source The result value of the source expression is the instance that performs the property call.

FeatureCallExp

A FeatureCallExp expression is an expression that refers to a feature that is defined for a Classifier in the UML model to which this expression is attached. Its result value is the evaluation of the corresponding feature.

Attributes

isPre Boolean indicating whether the expression accesses the precondition-time value of the referred feature.

IfExp

An IfExp is defined in 8.3.3, 'If Expressions’ but included in this diagram for completeness.

IterateExp

An IterateExp is an expression that evaluates its body expression for each element of a collection. It acts as a loop construct that iterates over the elements of its source collection and results in a value. An iterate expression evaluates its body expression for each element of its source collection. The evaluated value of the body expression in each iteration-step becomes the new value for the result variable for the succeeding iteration-step. The result can be of any type and is defined by the result association. The IterateExp is the most fundamental collection expression defined in the OCL Expressions package.
Associations

result  The Variable that represents the result variable.

IteratorExp
An IteratorExp is an expression that evaluates its body expression for each element of a collection. It acts as a loop construct that iterates over the elements of its source collection and results in a value. The type of the iterator expression depends on the name of the expression, and sometimes on the type of the associated source expression. The IteratorExp represents all other predefined collection operations that use an iterator. This includes select, collect, reject, forAll, exists, etc. The OCL Standard Library defines a number of predefined iterator expressions. Their semantics is defined in terms of the iterate expression in 11.7, 'Predefined Iterator Expressions.'

LiteralExp
A LiteralExp is an expression with no arguments producing a value. In general the result value is identical with the expression symbol. This includes things like the integer 1 or literal strings like 'this is a LiteralExp.'

LoopExp
A LoopExp is an expression that represents a loop construct over a collection. It has an iterator variable that represents the elements of the collection during iteration. The body expression is evaluated for each element in the collection. The result of a loop expression depends on the specific kind and its name.

Associations

iterator  The iterator variables. These variables are, each in its turn, bound to every element value of the source collection while evaluating the body expression.

body  The OclExpression that is evaluated for each element in the source collection.

MessageExp
MessageExp is defined in “Message Expressions” on page 48, but included in this diagram for completeness.

OclExpression
An OclExpression is an expression that can be evaluated in a given environment. OclExpression is the abstract superclass of all other expressions in the metamodel - except for the ExpressionInOcl container class. It is the top-level element of the OCL Expressions package. Every OclExpression has a type that can be statically determined by analyzing the expression and its context. Evaluation of an expression results in a value. Expressions with boolean result can be used as constraints (e.g., to specify an invariant of a class). Expressions of any type can be used to specify queries, initial attribute values, target sets, etc.

The environment of an OclExpression defines what model elements are visible and can be referred to in an expression. At the topmost level the environment will be defined by the Element to which the OCL expression is attached, for example by a Classifier if the OCL expression is used as an invariant. On a lower level, each iterator expression can also introduce one or more iterator variables into the environment. The environment is not modeled as a separate metaclass because it can be completely derived using derivation rules. The complete derivation rules can be found in Clause 9 (“Concrete Syntax”).
**StateExp**

A StateExp is an expression used to refer to a state of a class within an expression. It is used to pass directly to the pre-defined operation `oclIsInState` the reference of a state of a class defined in the UML model.

**Associations**

- `referredState` The State being referred.

**TypeExp**

A TypeExp is an expression used to refer to an existing meta type within an expression. It is used in particular to pass the reference of the meta type when invoking the operations `oclIsKindOf`, `oclIsTypeOf`, and `oclAsType`.

**Associations**

- `referredType` The type being referred.

**Variable**

Variables are typed elements for passing data in expressions. The variable can be used in expressions where the variable is in scope. This metaclass represents among others the variables `self` and `result` and the variables defined using the Let expression.

**Associations**

- `initExpression` The `OclExpression` that represents the initial value of the variable. Depending on the role that a variable declaration plays, the init expression might be mandatory.
- `representedParameter` The `Parameter` in the current operation this variable is representing. Any access to the variable represents an access to the parameter value.

**VariableExp**

A VariableExp is an expression that consists of a reference to a variable. References to the variables `self` and `result` or to variables defined by Let expressions are examples of such variable expressions.

**Associations**

- `referredVariable` The Variable to which this variable expression refers.

### 8.3.2 FeatureCall Expressions

A FeatureCallExp can refer to any of the subtypes of `Feature` as defined in the UML kernel. This is shown in Figure 8.3 by the three different subtypes, each of which is associated with its own type of `Element`.
AssociationClassCallExp

An AssociationClassCallExp is a reference to an AssociationClass defined in a UML model. It is used to determine objects linked to a target object by an association class. The expression refers to these target objects by the name of the target association class.

Associations

referredAssociationClass The AssociationClass to which this AssociationClassCallExp is a reference. This refers to an AssociationClass that is defined in the UML model.

PropertyCallExp

A PropertyCallExpression is a reference to an Attribute of a Classifier defined in a UML model. It evaluates to the value of the attribute.

Associations

referredProperty The Attribute to which this AttributeCallExp is a reference.

NavigationCallExp

A NavigationCallExp is a reference to a Property or an AssociationClass defined in a UML model. It is used to determine objects linked to a target object by an association, whether explicitly modeled as an Association or implicit. If there is a qualifier attached to the source end of the association, then additional qualifier expressions may be used to specify the values of the qualifying attributes.
Associations

qualifier The values for the qualifier attributes if applicable.

navigationSource The source denotes the association end Property at the end of the object itself. This is used to resolve ambiguities when the same Classifier is at more than one end (plays more than one role) in the same association. In other cases it can be derived.

OperationCallExp

An OperationCallExp refers to an operation defined in a Classifier. The expression may contain a list of argument expressions if the operation is defined to have parameters. In this case, the number and types of the arguments must match the parameters.

Associations

argument The arguments denote the arguments to the operation call. This is only useful when the operation call is related to an Operation that takes parameters.

referredOperation The Operation to which this OperationCallExp is a reference. This is an Operation of a Classifier that is defined in the UML model.

8.3.3 If Expressions

This sub clause describes the if expression in detail. Figure 8.4 shows the structure of the if expression.

Figure 8.4 - Abstract syntax metamodel for if expression

IfExp

An IfExp results in one of two alternative expressions depending on the evaluated value of a condition. Note that both the thenExpression and the elseExpression are mandatory. The reason behind this is that an if expression should always result in a value, which cannot be guaranteed if the else part is left out.
Associations

condition The \textit{OclExpression} that represents the boolean condition. If this condition evaluates to true, the result of the if expression is identical to the result of the \textit{thenExpression}. If this condition evaluates to false, the result of the if expression is identical to the result of the \textit{elseExpression}.

\begin{itemize}
  \item \textit{thenExpression} The \textit{OclExpression} that represents the then part of the if expression.
  \item \textit{elseExpression} The \textit{OclExpression} that represents the else part of the if expression.
\end{itemize}

8.3.4 Message Expressions

In the specification of communication between instances we unify the notions of asynchronous and synchronous communication. The structure of the message expressions is shown in Figure 8.5.

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{message_expressions.png}
\caption{The abstract syntax of Ocl messages}
\end{figure}

**MessageExp**

A \textit{MessageExp} is an expression that results in a collection of \textit{OclMessage} value. An \textit{OclMessage} is the unification of a signal sent, and an operation call. The target of the operation call or signal sent is specified by the \textit{target} \textit{OclExpression}. Arguments are \textit{OclExpressions}, in particular they may be unspecified value expressions for arguments whose value is not specified. It covers both synchronous and asynchronous actions.
Associations

**target**

The *OclExpression* that represents the target instance to which the signal is sent.

**argument**

The *OclExpressions* that represent the parameters to the *Operation* or *Signal*. The number and type of arguments should conform to those defined in the *Operation* or *Signal*. The order of the arguments is the same as the order of the parameters of the *Operation* or the attributes of a *Signal*.

**calledOperation**

If this is a message to request an operation call, this is the requested *CallOperationAction*.

**sentSignal**

If this is a UML signal sent, this is the *SendSignalAction*.

**UnspecifiedValueExp**

An *UnspecifiedValueExp* is an expression whose value is unspecified in an OCL expression. It is used within OCL messages to leave parameters of messages unspecified.

### 8.4 Literal Expressions

This sub clause defines the different types of literal expressions of OCL. It also refers to enumeration types and enumeration literals. Figure 8.6 shows all types of literal expressions.

![Figure 8.6 - Abstract syntax metamodel for Literal expression](image-url)

© ISO/IEC 2012 - All rights reserved

49
**Figure 8.7 - Abstract syntax metamodel for Collection and Tuple Literal expression**

**BooleanLiteralExp**

A `BooleanLiteralExp` represents the value true or false of the predefined type Boolean.

**Attributes**

- booleanSymbol: The `Boolean` that represents the value of the literal.

**CollectionItem**

A `CollectionItem` represents an individual element of a collection.

**CollectionKind**

The `CollectionKind` enumeration lists the kinds of collections. Its literals are `Collection`, `Set`, `OrderedSet`, `Bag`, and `Sequence`.

**CollectionLiteralExp**

A `CollectionLiteralExp` represents a reference to collection literal.
Attributes

kind The kind of collection literal that is specified by this `CollectionLiteralExp`.

Associations

part The parts of the collection literal expression.

`CollectionLiteralPart`

A `CollectionLiteralPart` is a member of the collection literal.

Associations

type The type of the collection literal.

`CollectionRange`

A `CollectionRange` represents a range of integers.

`EnumLiteralExp`

An `EnumLiteralExp` represents a reference to an enumeration literal.

Associations

referredEnumLiteral The `EnumLiteral` to which the enum expression refers.

`IntegerLiteralExp`

An `IntegerLiteralExp` denotes a value of the predefined type `Integer`.

Attributes

integerSymbol The `Integer` that represents the value of the literal.

`NumericLiteralExp`

A `NumericLiteralExp` denotes a value of either the type UnlimitedNatural, `Integer` or `Real` types.

`PrimitiveLiteralExp`

A `PrimitiveLiteralExp` literal denotes a value of a primitive type.
Attributes

symbol The String that represents the value of the literal.

RealLiteralExp
A RealLiteralExp denotes a value of the predefined type Real.

Attributes

realSymbol The Real that represents the value of the literal.

StringLiteralExp
A StringLiteralExp denotes a value of the predefined type String.

Attributes

stringSymbol The String that represents the value of the literal.

TupleLiteralExp
A TupleLiteralExp denotes a tuple value. It contains a name and a value for each part of the tuple type.

Associations

part The Variable declarations defining the parts of the literal.

UnlimitedNaturalLiteralExp
An UnlimitedNaturalLiteralExp denotes a value of the predefined type UnlimitedNatural.

Attributes

unlimitedNaturalSymbol The UnlimitedNatural that represents the value of the literal.

8.4.1 Let Expressions

This sub clause defines the abstract syntax metamodel for Let expressions. The only addition to the abstract syntax is the metaclass LetExp as shown in Figure 8.8. The other metaclasses are re-used from the previous diagrams.

Note: Let expressions that take arguments are no longer allowed in OCL 2.0. This feature is redundant. Instead, a modeler can define an additional operation in the UML Classifier, potentially with a special stereotype to denote that this operation is only meant to be used as a helper operation in OCL expressions. The postcondition of such an additional operation can then define its result value. Removal of Let functions will therefore not affect the expressibility of the modeler. Another way to define such helper operations is through the «definition» constraint, which reuses some of the concrete syntax defined for Let expressions (see 12.5, ‘Definition’), but is nothing more than an OCL-based syntax for defining helper attributes and operations.
LetExp

A LetExp is a special expression that defined a new variable with an initial value. A variable defined by a LetExp cannot change its value. The value is always the evaluated value of the initial expression. The variable is visible in the *in* expression.

Associations

- **variable** The *Variable* introduced by the Let expression.
- **in** The *OclExpression* in whose environment the defined variable is visible.

### 8.4.2 Well-formedness Rules of the Expressions package

The metaclasses defined in the abstract syntax have the following well-formedness rules:

**PropertyCallExp**

The type of the call expression is the type of the referred property.

```plaintext
class PropertyCallExp
  inv: type = referredProperty.type
```

**BooleanLiteralExp**

- [31] The type of a boolean Literal expression is the type Boolean.
  ```plaintext
class BooleanLiteralExp
  inv: self.type.name = 'Boolean'
  ```

**CollectionLiteralExp**

- [32] ‘Collection’ is an abstract class on the M1 level and has no M0 instances.
  ```plaintext
class CollectionLiteralExp
  inv: kind <> CollectionKind::Collection
  ```
- [33] The type of a collection literal expression is determined by the collection kind selection and the common supertype of all elements. Note that the definition below implicitly states that empty collections have *OclVoid* as their *elementType*.
  ```plaintext
class CollectionLiteralExp
  inv: kind = CollectionKind::Set implies type.oclIsKindOf (SetType)
  inv: kind = CollectionKind::OrderedSet implies type.oclIsKindOf (OrderedSetType)
  inv: kind = CollectionKind::Sequence implies type.oclIsKindOf (SequenceType)
  ```
inv: kind = CollectionKind::Bag implies type.oclIsKindOf (BagType)
inv: type.oclAsType (CollectionType).elementType = part->iterate (p; c : Classifier = OclVoid | c.commonSuperType (p.type))

**CollectionLiteralPart**

No additional well-formedness rules.

**CollectionItem**

[34][1] The type of a CollectionItem is the type of the item expression.

context CollectionItem
inv: type = item.type

**CollectionRange**

[35][1] The type of a CollectionRange is the common supertype of the expressions taking part in the range.

context CollectionRange
inv: type = first.type.commonSuperType (last.type)

**EnumLiteralExp**

[36][1] The type of an enum Literal expression is the type of the referred literal.

context EnumLiteralExp
inv: self.type = referredEnumLiteral.enumeration

**IfExp**

[37][1] The type of the condition of an if expression must be Boolean.

context IfExp
inv: self.condition.type.oclIsKindOf(PrimitiveType) and self.condition.type.name = ‘Boolean’

[38][2] The type of the if expression is the most common supertype of the else and then expressions.

context IfExp
inv: self.type = thenExpression.type.commonSuperType(elseExpression.type)

**IntegerLiteralExp**

[39][1] The type of an integer Literal expression is the type Integer.

context IntegerLiteralExp
inv: self.type.name = ‘Integer’

**IteratorExp any**

[40][1] There is exactly one iterator.

context IteratorExp
inv: name = ‘any’ implies iterator->size() = 1

[41][2] The type is the same as the source element type

context IteratorExp
inv: name = ‘any’ implies type = source.type.oclAsType(CollectionType).elementType

[42][3] The type of the body must be Boolean.

context IteratorExp
inv: name = ‘any’ implies body.type.oclIsKindOf(PrimitiveType) and body.type.name = ‘Boolean’
**IteratorExp closure**

[43][1] There is exactly one iterator.

```
context IteratorExp
inv: name = 'closure' implies iterator->size() = 1
```

[44][2] The collection type for an OrderedSet or a Sequence source type is OrderedSet. For any other source the collection type is Set.

```
context IteratorExp
inv: name = 'closure' implies
if source.type.oclIsKindOf(SequenceType) or source.type.oclIsKindOf(OrderedSetType) then
  type.oclIsKindOf(OrderedSetType)
else
  type.oclIsKindOf(SetType)
endif
```

[45][3] The source element type is the same as type of the body elements or element.

```
context IteratorExp
inv: name = 'closure' implies
source.type.oclAsType(CollectionType).elementType =
  if body.type.oclIsKindOf(CollectionType) then body.type.oclAsType(CollectionType).elementType
  else body.type
  endif
```

[46][4] The element type is the same as the source element type.

```
context IteratorExp
inv: name = 'closure' implies
type.oclAsType(CollectionType).elementType = source.type.oclAsType(CollectionType).elementType
```

**IteratorExp collect**

[47][1] There is exactly one iterator.

```
context IteratorExp
inv: name = 'collect' implies iterator->size() = 1
```

[48][2] The collection type for an OrderedSet or a Sequence type is a Sequence, the result type for any other collection type is a Bag.

```
context IteratorExp
inv: name = 'collect' implies
if source.type.oclIsKindOf(SequenceType) or source.type.oclIsKindOf(OrderedSetType) then
  type.oclIsKindOf(SequenceType)
else
  type.oclIsKindOf(BagType)
endif
```

[49][3] The element type is the type of the body elements.

```
context IteratorExp
inv: name = 'collect' implies
type.oclAsType(CollectionType).elementType =
  body.type.oclAsType(CollectionType).elementType
```
IteratorExp collectNested
[50][1] There is exactly one iterator.
    context IteratorExp
    inv: name = 'collectNested' implies iterator->size() = 1
[51][2] The type is a Bag.
    context IteratorExp
    inv: name = 'collectNested' implies type.oclIsKindOf(BagType)
[52][3] The type is the type of source.
    context IteratorExp
    inv: name = 'collectNested' implies type = body.type

IteratorExp exists
[53][1] The type must be Boolean.
    context IteratorExp
    inv: name = 'exists' implies type.oclIsKindOf(PrimitiveType) and type.name = 'Boolean'
[54][2] The type of the body must be Boolean.
    context IteratorExp
    inv: name = 'exists' implies body.type.oclIsKindOf(PrimitiveType) and body.type.name = 'Boolean'

IteratorExp forAll
[55][1] The type must be Boolean.
    context IteratorExp
    inv: name = 'forAll' implies type.oclIsKindOf(PrimitiveType) and type.name = 'Boolean'
[56][2] The type of the body must be Boolean.
    context IteratorExp
    inv: name = 'forAll' implies body.type.oclIsKindOf(PrimitiveType) and body.type.name = 'Boolean'

IteratorExp isUnique
[57][1] There is exactly one iterator.
    context IteratorExp
    inv: name = 'isUnique' implies iterator->size() = 1
[58][2] The type must be Boolean.
    context IteratorExp
    inv: name = 'isUnique' implies type.oclIsKindOf(PrimitiveType) and type.name = 'Boolean'

IteratorExp one
[59][1] There is exactly one iterator.
    context IteratorExp
    inv: name = 'one' implies iterator->size() = 1
[60][2] The type is Boolean
    context IteratorExp
    inv: name = 'one' implies type.oclIsKindOf(PrimitiveType) and type.name = 'Boolean'
[61][3] The type of the body must be Boolean.
    context IteratorExp
    inv: name = 'one' implies body.type.oclIsKindOf(PrimitiveType) and body.type.name = 'Boolean'
IteratorExp reject or select

[62][1] There is exactly one iterator.

context IteratorExp
inv: name = 'reject' or name = 'select' implies iterator->size() = 1

[63][2] The type is the same as the source.

context IteratorExp
inv: name = 'reject' or name = 'select' implies type = source.type

[64][3] The type of the body must be Boolean.

context IteratorExp
inv: name = 'reject' or name = 'select' implies
body.type.oclIsKindOf(PrimitiveType) and body.type.name = 'Boolean'

IteratorExp sortedBy

[65][1] There is exactly one iterator.

context IteratorExp
inv: name = 'sortedBy' implies iterator->size() = 1

[66][2] The collection type for an OrderedSet or a Sequence type is a Sequence, the result type for any other collection type is Bag.

context IteratorExp
inv: name = 'sortedBy' implies
if source.type.oclIsKindOf(SequenceType) or source.type.oclIsKindOf(BagType) then
type.oclIsKindOf(SequenceType)
else
type.oclIsKindOf(OrderedSetType)
endif

[67][3] The element type is the type of the body elements.

context IteratorExp
inv: name = 'sortedBy' implies
type.oclAsType(CollectionType).elementType =
body.type.oclAsType(CollectionType).elementType

IterateExp

[68][1] The type of the iterate is the type of the result variable.

context IterateExp
inv: type = result.type

[69][2] The type of the body expression must conform to the declared type of the result variable.

context IterateExp
inv: body.type.conformsTo(result.type)

[70][3] A result variable must have an init expression.

context IterateExp
inv: self.result.initExpression->size() = 1

LetExp

[71][1] The type of a Let expression is the type of the in expression.

context LetExp
inv: type = in.type
LiteralExp
No additional well-formedness rules.

LoopExp
[72][1] The type of the source expression must be a collection.
  \[\text{context LoopExp} \quad \text{inv: source.type.oclIsKindOf (CollectionType)}\]

[73][2] The loop variable of an iterator expression has no init expression.
  \[\text{context LoopExp} \quad \text{inv: self.iterator->forAll(initExpression->isEmpty())}\]

[74][3] The type of each iterator variable must be the type of the elements of the source collection.
  \[\text{context IteratorExp} \quad \text{inv: self.iterator->forAll(type = source.type.oclAsType (CollectionType).elementType)}\]

FeatureCallExp
No additional well-formedness rules.

NumericLiteralExp
No additional well-formedness rules.

OclExpression
No additional well-formedness rules.

MessageExp
[75][1] If the message is an operation call action, the arguments must conform to the parameters of the operation.
  \[\text{context MessageExp} \quad \text{inv: calledOperation->notEmpty() implies} \]
  \[\text{argument->forAll (a | a.type.conformsTo} \]
  \[\text{(self.calledOperation.operation.ownedParameter->}
  \quad \text{select( kind = ParameterDirectionKind::in )}
  \quad \text{->at (argument->indexOf (a).type))}\]

[76][2] If the message is a send signal action, the arguments must conform to the attributes of the signal.
  \[\text{context MessageExp} \quad \text{inv: sentSignal->notEmpty() implies} \]
  \[\text{argument->forAll (a | a.type.conformsTo} \]
  \[\text{(self.sentSignal.signal.ownedAttribute}
  \quad \text{->at (argument->indexOf (a).type))}\]

[77][3] If the message is a call operation action, the operation must be an operation of the type of the target expression.
  \[\text{context MessageExp} \quad \text{inv: calledOperation->notEmpty() implies} \]
  \[\text{target.type.allOperations()->includes(calledOperation.operation)}\]

[78][4] An OCL message has either a called operation or a sent signal.
  \[\text{context MessageExp} \quad \text{inv: calledOperation->size() + sentSignal->size() = 1}\]
The target of an OCL message cannot be a collection.

context MessageExp
inv: not target.type.oclIsKindOf(CollectionType)

OperationCallExp

All the arguments must conform to the parameters of the referred operation.

context OperationCallExp
inv: arguments->forAll (a | a.type.conformsTo (self.refParams->at (arguments->indexOf (a)).type))

There must be exactly as many arguments as the referred operation has parameters.

context OperationCallExp
inv: arguments->size() = refParams->size()

An additional attribute refParams lists all parameters of the referred operation except the return and out parameter(s).

context OperationCallExp
def: refParams: Sequence(Parameter) = referredOperation.ownedParameter->select (p |
  p.kind <> ParameterDirectionKind::return or
  p.kind <> ParameterDirectionKind::out)

CallExp

No additional well-formedness rules.

RealLiteralExp

The type of a real Literal expression is the type Real.

context RealLiteralExp
inv: self.type.name = 'Real'

StateExp

No additional well-formedness rules.

StringLiteralExp

The type of a string Literal expression is the type String.

context StringLiteralExp
inv: self.type.name = 'String'

TypeExp

No additional well-formedness rules.

TupleLiteralExp

The type of a TupleLiteralExp is a TupleType with the specified parts.

context TupleLiteralExp
inv: type.oclIsKindOf(TupleType)
  and part->size() = type.allProperties()->size()
  and part->forAll (tlep |
    type.allProperties()->exists (tp | tlep.attribute.name = tp.name and tlep.attribute.type = tp.type))
All tuple literal expression parts of one tuple literal expression have unique names.

context TupleLiteralExp
inv: part->isUnique (attribute.name)

**TupleLiteralPart**

The type of the attribute conforms to the type of the value expression.

context TupleLiteralPart
inv: attribute.type.conformsTo(value.type)

**UnlimitedNaturalLiteralExp**

The type of an unlimited natural Literal expression is the type UnlimitedNatural.

context UnlimitedNaturalLiteralExp
inv: self.type.name = 'UnlimitedNatural'

**UnspecifiedValueExp**

No additional well-formedness rules.

**Variable**

For initialized variable declarations, the type of the initExpression must conform to the type of the declared variable.

context Variable
inv: initExpression->notEmpty() implies initExpression.type.conformsTo (type)

**VariableExp**

The type of a VariableExp is the type of the variable to which it refers.

context VariableExp
inv: type = referredVariable.type

### 8.4.3 Additional Operations on UML metaclasses

In the clauses “Abstract Syntax,” “Concrete Syntax,” and “The Use of Ocl Expressions in UML Models” many additional operations on UML metaclasses are used. They are defined in this sub clause. The next sub clause defines additional operations for the OCL metaclasses.

**Classifier**

The operation commonSuperType results in the most specific common supertype of two classifiers.

context Classifier
def: commonSuperType (c : Classifier) : Classifier =
Classifier.allInstances()->select (cst |
c.conformsTo (cst) and
self.conformsTo (cst) and
not Classifier.allInstances()->exists (clst |
c.conformsTo (clst) and
self.conformsTo (clst) and
clst.conformsTo (cst) and
clst <> cst
)
)->any (true)

The following operations have been added to Classifier to lookup properties and operations.
context Classifier
def: lookupProperty(attName : String) : Attribute =
    self.allProperties()->any(me | me.name = attName)
def: lookupAssociationClass(name : String) : AssociationClass =
    self.allAssociationClasses()->any (ae | ae.name = name)
def: lookupOperation (name: String, paramTypes: Sequence(Classifier)) : Operation =
    self.allOperations()->any (op | op.name = name and
        op.hasMatchingSignature(paramTypes))
def: lookupSignal (sigName: String, paramTypes: Sequence(Classifier)) : Signal =
    self.allReceptions().signal->any (sig | sig.name = sigName and
        sig.hasMatchingSignature(paramTypes))
def: allReceptions() : Set(Reception) =
    self.allFeatures()->select(f | f.oclIsKindOf(Reception))
def: allProperties() : Set(Property) =
    self.allFeatures()->select(f | f.oclIsKindOf(Property))
def: allOperations() : Set(Property) =
    self.allFeatures()->select(f | f.oclIsKindOf(Operation))

The operation allFeatures() is defined in the UML semantics.

The operation allInstances()
context Classifier
def: allInstances() : Set(T) = -- all instances of self
returns all instances of the classifier and the classifiers specializing it. May only be used for classifiers that have a finite number of instances. This is the case, for example, for user defined classes because instances need to be created explicitly, and for enumerations, the standard Boolean type, and other special types such as OclVoid. This is not the case, for example, for data types such as collection types or the standard String, UnlimitedNatural, Integer, and Real types.

Operation
An additional operation is added to Operation, which checks whether its signature matches with a sequence of Classifiers. Note that in making the match only parameters with direction kind ‘in’ are considered.

context Operation
def: hasMatchingSignature(paramTypes: Sequence(Classifier)) : Boolean =
    -- check that operation op has a signature that matches the given parameter lists
    let sigParamTypes: Sequence(Classifier) = self.allProperties().type in
    (sigParamTypes->size() = paramTypes->size() ) and
    ( Set{1..paramTypes->size()}->forAll ( i |
        paramTypes->at (i).conformsTo (sigParamTypes->at (i)) )
    )

def: allProperties() : Set(Property) =
    self.ownedParameter->asProperty()

Parameter
The operation asProperty results in a property that has the same name, type, etc. as the parameter.

context Parameter::asProperty(): Property
pre: -- none
post: result.name = self.name
post: result.type = self.type
post: result.upperValue = 1
post: result.lowerValue = 1
post: result.isOrdered = true
post: result.isStatic = false
post: result.visibility = VisibilityKind::private

An additional class operation is added to Parameter to return a Parameter.

context Parameter::make(n : String, c : Classifier, k : ParameterDirectionKind) : Parameter
post: result.name = n
post: result.kind = k
post: result.type = c

Property

The operation cmpSlots returns true if the compared property has identical name and type.

context Parameter::cmpSlots(): Boolean =
result.name = self.name and result.type = self.type

Signal

An additional operation is added to Signal, which checks whether its signature matches with a sequence of Classifiers. Note that in making the match the parameters of the signal are its attributes.

context Signal
def: hasMatchingSignature(paramTypes: Sequence(Classifier)) : Boolean =
-- check that signal has a signature that matches the given parameter lists
let opParamTypes: Sequence(Classifier) = self.ownedParameter->select (p | p.kind <> ParameterDirectionKind::return).type in

( opParamTypes->size() = paramTypes->size() ) and
( Set{1..paramTypes->size()}->forAll ( i |
paramTypes->at (i).conformsTo (opParamTypes->at (i))
)
)

State

The operation getStateMachine() returns the statemachine to which a state belongs.

context State::getStateMachine() : StateMachine
post: result = container.stateMachine

Transition

The operation getStateMachine() returns the statemachine to which a transition belongs.

context Transition::getStateMachine() : StateMachine
post: result = container.stateMachine

8.4.4 Additional Operations on OCL Metaclasses

In clauses “Abstract Syntax,” “Concrete Syntax,” and “The Use of Ocl Expressions in UML Models” many additional operations on OCL metaclasses are used. They are defined in this sub clause. The previous sub clause defines additional operations for the UML metaclasses.
OclExpression

The following operation returns an operation call expression for the predefined \texttt{asSet()} operation with the self expression as its source.

\[
\text{context OclExpression::withAsSet() : OperationCallExp}
\]
\[
\text{post: result.name = 'asSet'}
\]
\[
\text{post: result.argument->isEmpty()}
\]
\[
\text{post: result.source = self}
\]

TupleType

An additional class operation is added to Tuple to return a new tuple. The name of a tupletype is defined in the abstract syntax clause and need not be specified here.

\[
\text{context TupleType::make(atts : Sequence(Property) ) : TupleType}
\]
\[
\text{post: Sequence\{1...atts->size()\}->forAll(i | result.ownedAttribute.at(i).cmpSlots(atts.at(i))}
\]

Variable

An additional operation is added to Variable to return a corresponding Parameter.

\[
\text{context Variable::asParameter() : Parameter}
\]
\[
\text{post: result.name = self.name}
\]
\[
\text{post: result.direction = ParameterDirectionKind::in}
\]
\[
\text{post: result.type = self.type}
\]

An additional operation is added to Variable to return a corresponding Property.

\[
\text{context Variable::asProperty() : Attribute}
\]
\[
\text{post: result.name = self.name}
\]
\[
\text{post: result.type = self.type}
\]
\[
\text{upperValue = 1}
\]
\[
\text{post: result.lowerValue = 1}
\]
\[
\text{post: result.isOrdered = true}
\]
\[
\text{post: result.isStatic = false}
\]
\[
\text{post: result.visibility = VisibilityKind::private}
\]
\[
\text{post: result.constraint.specification.bodyExpression = self.initExpression}
\]
8.4.5 Overview of class hierarchy of OCL Abstract Syntax metamodel

Figure 8.9 - Overview of the abstract syntax metamodel for Expressions
9 Concrete Syntax

9.1 General

This clause describes the concrete syntax of the OCL. This allows modelers to write down OCL expressions in a standardized way. A formal mapping from the concrete syntax to the abstract syntax from Clause 8 (“Abstract Syntax”) is given. Although not required, 9.6, ‘Concrete to Abstract Syntax Mapping’ describes a mapping from the abstract syntax to the concrete syntax. This allows one to produce a standard human readable version of any OCL expression that is represented as an instance of the abstract syntax.

9.2 ‘Structure of the Concrete Syntax’ describes the structure of the grammar and the motivation for the use of an attribute grammar.

9.2 Structure of the Concrete Syntax

The concrete syntax of OCL is described in the form of a full attribute grammar. Each production in an attribute grammar may have synthesized attributes attached to it. The value of synthesized attributes of elements on the left hand side of a production rule is always derived from attributes of elements at the right hand side of that production rule. Each production may also have inherited attributes attached to it. The value of inherited attributes of elements on the right hand side of a production rule is always derived from attributes of elements on the left hand side of that production.

In the attribute grammar that specifies the concrete syntax, every production rule is denoted using the EBNF formalism and annotated with synthesized and inherited attributes, and disambiguating rules. There are a number of special annotations, as follows.

Synthesized Attributes

Each production rule has one synthesized attribute called ast (short for abstract syntax tree), that holds the instance of the OCL Abstract Syntax that is returned by the rule. The type of ast is different for every rule, but it always is an element of the abstract syntax. The type is stated with each production rule under the heading “Abstract Syntax Mapping.” The ast attribute constitutes the formal mapping from concrete syntax to abstract syntax.

The motivation for the use of an attribute grammar is the easiness of the construction and the clarity of this mapping. Note that each name in the EBNF format of the production rule is postfixed with ‘CS’ to clearly distinguish between the concrete syntax elements and their abstract syntax counterparts.

Inherited Attributes

Each production rule has one inherited attribute called env (short for environment), that holds a list of names that are visible from the expression. All names are references to elements in the model. In fact, env is a name space environment for the expression or expression part denoted according to the production rule. The type of the env attribute is Environment, as shown in Figure 9.1. A number of operations are defined for this type. Their definitions and more details on the Environment type can be found in “Concrete Syntax” on page 67. The manner in which both the ast and env attributes are determined is given using OCL expressions.
Figure 9.1 - The Environment type

Note that the contents of the \textit{env} attribute are fully determined by the context of the OCL expression. When an OCL expression is used as an invariant to class X, its environment will be different than in the case the expression is used as a postcondition to an operation of class Y. In Clause 12 ("The Use of Ocl Expressions in UML Models") the context of OCL expressions is defined in detail.

Multiple Production Rules

For some elements there is a choice of multiple production rules. In that case the EBNF format of each production rule is prefixed by a capital letter between square brackets. The same prefix is used for the corresponding determination rules for the \textit{ast} and \textit{env} attributes.

Multiple Occurrences of Production Names

In some production rules the same element name is used more than once. To distinguish between these occurrences the names will be postfixed by a number in square brackets, as in the following example.

\[
\text{CollectionRangeCS} ::= \text{OclExpressionCS}[1] \ldots \text{OclExpressionCS}[2]
\]

Disambiguating Rules

Some of the production rules are syntactically ambiguous. For such productions disambiguating rules have been defined. Using these rules, each production and thus the complete grammar becomes nonambiguous. For example in parsing \textit{a.b()}, there are at least three possible parsing solutions:

1. \textit{a} is a \textit{VariableExpr} (a reference to a let or an iterator variable)
2. \( a \) is an AttributeCallExp (self is implicit)

3. \( a \) is a NavigationCallExp (self is implicit)

A decision on which grammar production rule to use can only be made when the environment of the expression is taken into account. The disambiguating rules describe these choices based on the environment and allow unambiguous parsing of \( a.b() \). In this case the rules (in plain English) would be:

- If \( a \) is a defined variable in the current scope, \( a \) is a VariableExp.
- If not, check self and all iterator variables in scope. The inner-most scope for which as is either
  - an attribute with the name \( a \), resulting in an AttributeCallExp, or
  - an opposite association-end with the name \( a \), resulting in a NavigationCallExp, defines the meaning of \( a.b() \).
- If neither of the above is true, the expression is illegal / incorrect and cannot be parsed.

Disambiguating rules may be based on the UML model to which the OCL expression is attached (e.g., does an attribute exist or not). Because of this, the UML model must be available when an OCL expression is parsed, otherwise it cannot be validated as a correct expression. The grammar is structured in such a way that at most one of the production rules will fulfill all the disambiguating rules, thus ensuring that the grammar as a whole is unambiguous. The disambiguating rules are written in OCL, and use some metaclasses and additional operations from UML.

### 9.3 A Note to Tool Builders

#### 9.3.1 Parsing

The grammar in this clause might not prove to be the most efficient way to directly construct a tool. Of course, a tool-builder is free to use a different parsing mechanism. He can, for example, first parse an OCL expression using a special concrete syntax tree, and do the semantic validation against a UML model in a second pass. Also, error correction or syntax directed editing might need hand-optimized grammars. This document does not prescribe any specific parsing approach. The only restriction is that at the end of all processing a tool should be able to produce the same well-formed instance of the abstract syntax, as would be produced by this grammar.

#### 9.3.2 Visibility

The OCL specification puts no restriction on the visibility declared for a property defined in the model (such as ‘private,’ ‘protected,’ or ‘public’). In OCL, all modelelements are considered visible. The reason for this is to allow a modeler to specify constraints, even between ‘hidden’ elements. At the lowest implementation level this might be useful.

As a separate option OCL tools may enforce all UML visibility rules to support OCL expressions to be specified only over visible modelelements. Especially when a tool needs to generate code for runtime evaluation of OCL expressions, this visibility enforcement is necessary.

### 9.4 Concrete Syntax

In the concrete syntax, names that are reserved words or include punctuation characters can be used by enclosing the required name in underscore-prefixed single quotes.

\[
_{'\text{and}'}, _{\text{>='}}
\]
[In OCL 2.0 and 2.2 a reserved word could be used as a name after prefixing it with an underscore. 

_and

The subsequent symbol lookup would look first for the spelling with an underscore in the meta-model and if that was not found would attempt a further lookup after removing the underscore. This behavior was indeterminate, could not access names that existed both with and without prefixes, and did not support punctuation characters. The simple underscore prefix is therefore deprecated in OCL 2.3 and will be removed in OCL 3.0.]

9.4.1 ExpressionInOclCS

The ExpressionInOcl symbol has been added to set up the initial environment of an expression.

ExpressionInOclCS ::= OclExpressionCS

Abstract syntax mapping

ExpressionInOclCS.ast : OclExpression

Synthesized attributes

ExpressionInOclCS.ast = OclExpressionCS.ast

Inherited attributes

The environment of the OCL expression must be defined, but what exactly needs to be in the environment depends on the context of the OCL expression. The following rule is therefore not complete. It defines the env attribute by adding the self variable to an empty environment, as well as a Namespace containing all elements visible from self. In sub clause 12.2, the contextualClassifier will be defined for the various places where an ocl expression may occur. In the context of a pre- or postcondition, the result variable as well as variable definitions for any named operation parameters can be added in a similar way.

OclExpressionCS.env =
   ExpressionInOclCS.contextualClassifier.namespace.getEnvironmentWithParents()
   .addElement (‘self,’ ExpressionInOclCS.contextualClassifier, true)

9.4.2 OclExpressionCS

An OclExpression has several production rules, one for each subclass of OclExpression. Note that UnspecifiedValueExp is handled explicitly in OclMessageArgCS, because that is the only place where it is allowed.

[A] OclExpressionCS ::= CallExpCS
[B] OclExpressionCS ::= VariableExpCS
[C] OclExpressionCS ::= LiteralExpCS
[D] OclExpressionCS ::= LetExpCS
[E] OclExpressionCS ::= OclMessageExpCS
[F] OclExpressionCS ::= IfExpCS

Abstract syntax mapping

OclExpressionCS.ast : OclExpression
Synthesized attributes

[A] OclExpressionCS.ast = CallExpCS.ast
[B] OclExpressionCS.ast = VariableExpCS.ast
[C] OclExpressionCS.ast = LiteralExpCS.ast
[D] OclExpressionCS.ast = LetExpCS.ast
[E] OclExpressionCS.ast = OclMessageExpCS.ast
[F] OclExpressionCS.ast = IfExpCS.ast

Inherited attributes

[A] CallExpCS.env = OclExpressionCS.env
[B] VariableExpCS.env = OclExpressionCS.env
[C] LiteralExpCS.env = OclExpressionCS.env
[D] LetExpCS.env = OclExpressionCS.env
[E] OclMessageExpCS.env = OclExpressionCS.env
[F] IfExpCS.env = OclExpressionCS.env

Disambiguating rules

The disambiguating rules are defined in the children.

9.4.3 VariableExpCS

A variable expression is just a name that refers to a variable or self.
[A] VariableExpCS ::= simpleNameCS
[B] VariableExpCS ::= 'self'

Abstract syntax mapping

VariableExpCS.ast : VariableExpression

Synthesized attributes

[A] VariableExpCS.ast.referredVariable =
   env.lookup(simpleNameCS.ast).referredElement.oclAsType(VariableDeclaration)
[B] VariableExpCS.ast.referredVariable =
   env.lookup('self').referredElement.oclAsType(VariableDeclaration)

Inherited attributes

-- none

Disambiguating rules

[91][1][A] simpleNameCS must be a name of a visible VariableDeclaration in the current
   environment
   env.lookup(simpleNameCS.ast).referredElement.oclIsKindOf(VariableDeclaration)

9.4.4 simpleNameCS

This production rule represents a single name. No special rules are applicable. The abstract syntax of a simpleNameCS
String is undefined in UML 2.3, and so is undefined in OCL 2.3. The reason for this is internationalization.

The concrete syntax of a simpleNameCS String supports a Unicode letter-prefixed identifier (form [A]). Reserved words
and names involving awkward characters such as punctuation may be specified by prefixing a String Literal with an ‘_’
(form [B] and [C]).
The identifier form starts with a Unicode letter:

NameStartChar ::= [A-Z] | "_" | "$" | [a-z] | \[xC0-xD6] | \[xD8-xF6] | \[xF8-\#x2FF] | \[\#x370-\#x37D] | \[\#x37F-\#x1FFF] | \[\#x200C-\#x200D] | \[\#x2070-\#x218F] | \[\#x2C00-\#x2FEF] | \[\#x3001-\#xD7FF] | \[\#xF900-\#xFDCF] | \[\#xFDF0-\#xFFFD] | \[\#x10000-\#xEFFFF]

and may continue with a Unicode letter or digit.

NameChar ::= NameStartChar | [0-9]

The StringChar form is defined under StringLiteralExpCS.

Example simpleNameCS values are:

String    i3    αρετη    MAX_VALUE    isLetterOrDigit    _'true'    _'='    _'\''

Abstract syntax mapping

simpleNameCS.ast : String

Synthesized attributes

[A] simpleNameCS.ast = <CodePoints of NameStartChar NameChar*>  
[B] simpleNameCS.ast = <CodePoints of StringChar*>  

Inherited attributes

-- none

Disambiguating rules

[1] [A] the character, if any, following the last NameChar is not a NameChar.  
[2] [A] simpleNameCS.ast is not a reserved word  
[3] [B] No whitespace is permitted between the '_' and the first NameChar.  
[4] [C] simpleNameCS[2] is a simpleNameCS [B] or [C].

9.4.5 restrictedKeywordCS

This production rule represents any name that is not a reserved keyword.

[A] restrictedKeywordCS ::= CollectionTypeIdentifierCS  
[B] restrictedKeywordCS ::= primitiveTypeCS  
[C] restrictedKeywordCS ::= oclTypeCS  
[D] restrictedKeywordCS ::= 'Tuple'

Abstract syntax mapping

restrictedKeywordCS.ast : String
Synthesized attributes
[A] restrictedKeywordCS.ast = CollectionTypeIdentifierCS.ast.name
[B] restrictedKeywordCS.ast = primitiveTypeCS.ast.name
[C] restrictedKeywordCS.ast = oclTypeCS.ast.name
[D] restrictedKeywordCS.ast = 'Tuple'

Inherited attributes
-- none

Disambiguating rules
-- none

9.4.6 unreservedSimpleNameCS
This production rule represents any name that is not a reserved keyword.

[A] unreservedSimpleNameCS ::= simpleNameCS
[B] unreservedSimpleNameCS ::= restrictedKeywordCS

Abstract syntax mapping
unreservedSimpleNameCS.ast : String

Synthesized attributes
[A] unreservedSimpleNameCS.ast = simpleNameCS.ast
[B] unreservedSimpleNameCS.ast = restrictedKeywordCS.ast

Inherited attributes
-- none

Disambiguating rules
-- none

9.4.7 pathNameCS
This rule represents a path name, which is held in its ast as a sequence of Strings.

[A] pathNameCS ::= simpleNameCS
[B] pathNameCS ::= pathNameCS '::' unreservedSimpleNameCS

Abstract syntax mapping
pathNameCS.ast : Sequence(String)

Synthesized attributes
[A] pathNameCS.ast = Sequence{simpleNameCS.ast}
[B] pathNameCS.ast = pathNameCS.ast->append(unreservedSimpleNameCS.ast)

Inherited attributes
-- none

Disambiguating rules
-- none
9.4.8 LiteralExpCS

This rule represents literal expressions.

[A] LiteralExpCS ::= EnumLiteralExpCS
[B] LiteralExpCS ::= CollectionLiteralExpCS
[C] LiteralExpCS ::= TupleLiteralExpCS
[D] LiteralExpCS ::= PrimitiveLiteralExpCS
[E] LiteralExpCS ::= TypeLiteralExpCS

Abstract syntax mapping

LiteralExpCS.ast : LiteralExp

Synthesized attributes

[A] LiteralExpCS.ast = EnumLiteralExpCS.ast
[B] LiteralExpCS.ast = CollectionLiteralExpCS.ast
[C] LiteralExpCS.ast = TupleLiteralExpCS.ast
[D] LiteralExpCS.ast = PrimitiveLiteralExpCS.ast
[E] LiteralExpCS.ast = TypeLiteralExpCS.ast

Inherited attributes

[A] EnumLiteralExpCS.env = LiteralExpCS.env
[B] CollectionLiteralExpCS.env = LiteralExpCS.env
[C] TupleLiteralExpCS.env = LiteralExpCS.env
[D] PrimitiveLiteralExpCS.env = LiteralExpCS.env
[E] TypeLiteralExpCS.env = LiteralExpCS.env

Disambiguating rules

-- none

9.4.9 EnumLiteralExpCS

The rule represents Enumeration Literal expressions.

EnumLiteralExpCS ::= pathNameCS '::' simpleNameCS

Abstract syntax mapping

EnumLiteralExpCS.ast : EnumLiteralExp

Synthesized attributes

EnumLiteralExpCS.ast.type =
  env.lookupPathName (pathNameCS.ast).referredElement.oclAsType (Classifier)
EnumLiteralExpCS.ast.referredEnumLiteral =
  EnumLiteralExpCS.ast.type.oclAsType (Enumeration).literal->
    select (l | l.name = simpleNameCS.ast )->any(true)

Inherited attributes

-- none

Disambiguating rules

[92][1] The specified name must indeed reference an enumeration:
not EnumLiteralExpCS.ast.type.oclIsUndefined() and
EnumLiteralExpCS.ast.type.oclIsKindOf(Enumeration)

9.4.10 CollectionLiteralExpCS

This rule represents a collection literal expression.

CollectionLiteralExpCS ::= CollectionTypeIdentifierCS
                        ‘{’ CollectionLiteralPartsCS? ‘}’

Abstract syntax mapping
CollectionLiteralExpCS.ast : CollectionLiteralExp

Synthesized attributes
CollectionLiteralExpCS.ast.parts = CollectionLiteralPartsCS.ast
CollectionLiteralExpCS.ast.kind = CollectionTypeIdentifierCS.ast

Inherited attributes
CollectionTypeIdentifierCS.env = CollectionLiteralExpCS.env
CollectionLiteralPartsCS.env   = CollectionLiteralExpCS.env

Disambiguating rules
[93][1] In a literal the collection type may not be Collection.
CollectionTypeIdentifierCS.ast <> ‘Collection’

9.4.11 CollectionTypeIdentifierCS

This rule represents the type identifier in a collection literal expression. The Collection type is an abstract type on M1 level, so it has no corresponding literals.

[A] CollectionTypeIdentifierCS ::= ‘Set’
[B] CollectionTypeIdentifierCS ::= ‘Bag’
[C] CollectionTypeIdentifierCS ::= ‘Sequence’
[D] CollectionTypeIdentifierCS ::= ‘Collection’
[E] CollectionTypeIdentifierCS ::= ‘OrderedSet’

Abstract syntax mapping
CollectionTypeIdentifierCS.ast : CollectionKind

Synthesized attributes
[A] CollectionTypeIdentifierCS.ast = CollectionKind::Set
[B] CollectionTypeIdentifierCS.ast = CollectionKind::Bag
[C] CollectionTypeIdentifierCS.ast = CollectionKind::Sequence
[D] CollectionTypeIdentifierCS.ast = CollectionKind::Collection
[E] CollectionTypeIdentifierCS.ast = CollectionKind::OrderedSet

Inherited attributes
-- none
Disambiguating rules

-- none

9.4.12 CollectionLiteralPartsCS

This production rule describes a sequence of items that are the contents of a collection literal.

\[ \text{CollectionLiteralPartsCS}[1] = \text{CollectionLiteralPartCS} (',', \text{CollectionLiteralPartsCS}[2])? \]

Abstract syntax mapping

\[ \text{CollectionLiteralPartsCS}[1].\text{ast} : \text{Sequence(CollectionLiteralPart)} \]

Synthesized attributes

\[ \text{CollectionLiteralPartsCS}[1].\text{ast} = \text{Sequence(CollectionLiteralPartCS.ast)} \rightarrow \text{union(CollectionLiteralPartsCS[2].ast)} \]

Inherited attributes

\[ \text{CollectionLiteralPartCS.env} = \text{CollectionLiteralPartsCS[1].env} \]
\[ \text{CollectionLiteralPartSCS[2].env} = \text{CollectionLiteralPartsCS[1].env} \]

Disambiguating rules

-- none

9.4.13 CollectionLiteralPartCS

[A] CollectionLiteralPartCS ::= CollectionRangeCS

[B] CollectionLiteralPartCS ::= OclExpressionCS

Abstract syntax mapping

\[ \text{CollectionLiteralPartCS.ast} : \text{CollectionLiteralPart} \]

Synthesized attributes

[A] CollectionLiteralPartCS.ast = CollectionRange.ast

[B] CollectionLiteralPartCS.ast.oclIsKindOf(CollectionItem) and

\[ \text{CollectionLiteralPartCS.ast.oclAsType(CollectionItem).OclExpression} = \text{OclExpressionCS.ast} \]

Inherited attributes

[A] CollectionRangeCS.env = CollectionLiteralPartCS.env

[B] OclExpressionCS.env = CollectionLiteralPartCS.env

Disambiguating rules

-- none

9.4.14 CollectionRangeCS

\[ \text{CollectionRangeCS ::= OclExpressionCS[1] ' , ' OclExpressionCS[2]} \]
Abstract syntax mapping
CollectionRangeCS.ast : CollectionRange

Synthesized attributes
CollectionRangeCS.ast.first = OclExpressionCS[1].ast
CollectionRangeCS.ast.last = OclExpressionCS[2].ast

Inherited attributes
OclExpressionCS[1].env = CollectionRangeCS.env
OclExpressionCS[2].env = CollectionRangeCS.env

Disambiguating rules
-- none

9.4.15 PrimitiveLiteralExpCS
This includes Real, Boolean, UnlimitedNatural, Integer, and String literals. Especially String literals must take internationalization into account and might need to remain undefined in this specification.

[A] PrimitiveLiteralExpCS ::= IntegerLiteralExpCS
[B] PrimitiveLiteralExpCS ::= RealLiteralExpCS
[C] PrimitiveLiteralExpCS ::= StringLiteralExpCS
[D] PrimitiveLiteralExpCS ::= BooleanLiteralExpCS
[E] PrimitiveLiteralExpCS ::= UnlimitedNaturalLiteralExpCS
[F] PrimitiveLiteralExpCS ::= NullLiteralExpCS
[G] PrimitiveLiteralExpCS ::= InvalidLiteralExpCS

Abstract syntax mapping
PrimitiveLiteralExpCS.ast : PrimitiveLiteralExp

Synthesized attributes
[A] PrimitiveLiteralExpCS.ast = IntegerLiteralExpCS.ast
[B] PrimitiveLiteralExpCS.ast = RealLiteralExpCS.ast
[C] PrimitiveLiteralExpCS.ast = StringLiteralExpCS.ast
[D] PrimitiveLiteralExpCS.ast = BooleanLiteralExpCS.ast
[E] PrimitiveLiteralExpCS.ast = UnlimitedNaturalLiteralExpCS.ast
[F] PrimitiveLiteralExpCS.ast = NullLiteralExpCS.ast
[G] PrimitiveLiteralExpCS.ast = InvalidLiteralExpCS.ast

Inherited attributes
-- none

Disambiguating rules
-- none
9.4.16 TupleLiteralExpCS

This rule represents tuple literal expressions.

\[
\text{TupleLiteralExpCS} ::= \text{`Tuple` `{ `variableDeclarationListCS `}`}
\]

Abstract syntax mapping

\[
\text{TupleLiteralExpCS.ast : TupleLiteralExp}
\]

Synthesized attributes

\[
\text{TupleLiteralExpCS.tuplePart = variableDeclarationListCS.ast}
\]

Inherited attributes

\[
\text{variableDeclarationListCS[1].env = TupleLiteralExpCS.env}
\]

Disambiguating rules

[1] The initExpression and type of all VariableDeclarations must exist.

\[
\text{TupleLiteralExpCS.tuplePart->forAll( varDecl |}
\text{ varDecl.initExpression->notEmpty() and not varDecl.type.oclIsUndefined() )}
\]

9.4.17 UnlimitedNaturalLiteralExpCS

This rule represents unlimited natural literal expressions. The lexical representation is either the lexical representation of an integer value or the single character * that represents the unlimited value. The -1 representation of the unlimited value is only visible in the abstract syntax and its serialization.

\[
\begin{align*}
[A] & \text{UnlimitedNaturalLiteralExpCS ::= <Integer Lexical Representation>} \\
[B] & \text{UnlimitedNaturalLiteralExpCS ::= `*`}
\end{align*}
\]

Abstract syntax mapping

\[
\text{UnlimitedNaturalLiteralExpCS.ast : UnlimitedNaturalLiteralExp}
\]

Synthesized attributes

\[
\begin{align*}
\text{UnlimitedNaturalLiteralExpCS.ast.unlimitedNaturalSymbol = <IntegerValue>} \\
\text{UnlimitedNaturalLiteralExpCS.ast.unlimitedNaturalSymbol = -1}
\end{align*}
\]

Inherited attributes

-- none

Disambiguating rules

-- none

9.4.18 IntegerLiteralExpCS

This rule represents integer literal expressions. The lexical representation of an integer is a sequence of at least one of the decimal digit characters, without a leading zero; except that a single leading zero character is required for the zero value.

\[
\text{IntegerLiteralExpCS ::= <Integer Lexical Representation>}
\]

Abstract syntax mapping

\[
\text{IntegerLiteralExpCS.ast : IntegerLiteralExp}
\]
Synthesized attributes

IntegerLiteralExpCS.ast.integerSymbol = <Integer Value>

Inherited attributes

-- none

Disambiguating rules

-- none

9.4.19 RealLiteralExpCS

This rule represents real literal expressions. A real literal consists of an integer part, a fractional part and an exponent part. The exponent part consists of either the letter 'e' or 'E', followed optionally by a '+' or '-' letter followed by an exponent integer part. Each integer part consists of a sequence of at least one of the decimal digit characters. The fractional part consists of the letter '.' followed by a sequence of at least one of the decimal digit characters. Either the fraction part or the exponent part may be missing but not both.

RealLiteralExpCS ::= <Real Lexical Representation>

Abstract syntax mapping

RealLiteralExpCS.ast : RealLiteralExp

Synthesized attributes

RealLiteralExpCS.ast.realSymbol = <Real Value>

Inherited attributes

-- none

Disambiguating rules

-- none

9.4.20 StringLiteralExpCS

This rule represents string literal expressions. The concrete syntax comprises a sequence of zero or more characters or escape sequences surrounded by single quote characters. The [B] form with adjacent strings allows a long string literal to be split into fragments or to be written across multiple lines.

[A] StringLiteralExpCS ::= #x27 StringChar* #x27

where

StringChar ::= Char | EscapeSequence
WhiteSpaceChar ::= #x09 | #x0a | #x0c | #x0d | #x20
Char ::= [#x20-#x26] | [#x28-#x5B] | [#x5D-#xD7FF] | [#xE000-#xFFFD] | [#x10000-#x10FFFF]
EscapeSequence ::= \'\' | '\b' | '\t' | '\n' | '\f' | '\r' | '\"' | '\\' -- #x08: backspace BS

© ISO/IEC 2012 - All rights reserved
Abstract syntax mapping
StringLiteralExpCS.ast : StringLiteralExp

Synthesized attributes
[A] StringLiteralExpCS.ast.symbol = <CodePoints of StringChar*>  

Inherited attributes
-- none

Disambiguating rules
-- none

9.4.21 BooleanLiteralExpCS
This rule represents boolean literal expressions.
[94] [A] BooleanLiteralExpCS ::= ‘true’  
[95] [B] BooleanLiteralExpCS ::= ‘false’

Abstract syntax mapping
BooleanLiteralExpCS.ast : BooleanLiteralExp

Synthesized attributes
[A] BooleanLiteralExpCS.ast.booleanSymbol = true  
[B] BooleanLiteralExpCS.ast.booleanSymbol = false

Inherited attributes
-- none

9.4.22 TypeLiteralExpCS
This production rule references a type name.

Abstract syntax mapping
TypeLiteralExpCS ::= typeCS

Synthesized attributes
TypeLiteralExpCS.ast = typeCS.ast
Inherited attributes

typeCS.env = TypeLiteralExpCS.env

Disambiguating rules
-- none

9.4.23 CallExpCS

This rule represents property call expressions.

[96] [A] CallExpCS ::= FeatureCallExpCS
[97] [B] CallExpCS ::= LoopExpCS

Abstract syntax mapping
CallExpCS.ast : CallExp

Synthesized attributes

[A] CallExpCS.ast = ModelPropertyCallCS.ast
[B] CallExpCS.ast = LoopExpCS.ast

Inherited attributes

[A] ModelPropertyCallCS.env = CallExpCS.env
[B] LoopExpCS.env = CallExpCS.env

Disambiguating rules
The disambiguating rules are defined in the children.

9.4.24 LoopExpCS

This rule represents loop expressions.

[A] LoopExpCS ::= IteratorExpCS
[B] LoopExpCS ::= IterateExpCS

Abstract syntax mapping
LoopExpCS.ast : LoopExp

Synthesized attributes

[A] LoopExpCS.ast = IteratorExpCS.ast
[B] LoopExpCS.ast = IterateExpCS.ast

Inherited attributes

[A] IteratorExpCS.env = LoopExpCS.env
[B] IterateExpCS.env = LoopExpCS.env

Disambiguating rules
-- none
9.4.25 IteratorExpCS

The first alternative is a straightforward Iterator expression, with optional iterator variable. The second and third alternatives are so-called implicit collect iterators. B is for operations and C for attributes, D for navigations, and E for association classes.

[A] IteratorExpCS ::= OclExpressionCS[1] ‘->’ simpleNameCS

‘(’ (VariableDeclarationCS[1],

(‘,’ VariableDeclarationCS[2])? ‘|’ )?
OclExpressionCS[2]

‘)’

[B] IteratorExpCS ::= OclExpressionCS ‘.’ simpleNameCS ‘(argumentsCS?)’

[C] IteratorExpCS ::= OclExpressionCS ‘.’ simpleNameCS

[D] IteratorExpCS ::= OclExpressionCS ‘.’ simpleNameCS

(‘[‘ argumentsCS ‘]’)?

[E] IteratorExpCS ::= OclExpressionCS ‘.’ simpleNameCS

(‘[‘ argumentsCS ‘]’)?

Abstract syntax mapping

IteratorExpCS.ast : IteratorExp

Synthesized attributes

-- the ast needs to be determined bit by bit, first the source association of IteratorExp

[A] IteratorExpCS.ast.source = OclExpressionCS[1].ast

-- next the iterator association of IteratorExp

[E] typeCS.ast = oclTypeCS.ast

Inherited attributes

[B] collectionTypeCS.env = typeCS.env
[C] tupleTypeCS.env = typeCS.env

Disambiguating rules

[105][1] [A] pathName must be a name of a Classifier in current environment.

typeCS.env.lookupPathName(pathNameCS.ast).referredElement.oclIsKindOf(Classifier)

9.4.29 primitiveTypeCS

This production rule denotes a primitive type.

Abstract syntax mapping

[A] primitiveTypeCS ::= 'Boolean'
[B] primitiveTypeCS ::= 'Integer'
[C] primitiveTypeCS ::= 'Real'
[D] primitiveTypeCS ::= 'String'
[E] primitiveTypeCS ::= 'UnlimitedNatural'

Synthesized attributes

[A] primitiveTypeCS.ast = Boolean
ISO/IEC 19507:2012(E)

[B] primitiveTypeCS.ast = Integer
[C] primitiveTypeCS.ast = Real
[D] primitiveTypeCS.ast = String
[E] primitiveTypeCS.ast = UnlimitedNatural

Inherited attributes
-- none

Disambiguating rules
-- none

9.4.30 oclTypeCS

This production rule denotes a built-in OCL type.

Abstract syntax mapping
[A] oclTypeCS ::= 'OclAny'
[B] oclTypeCS ::= 'OclInvalid'
[C] oclTypeCS ::= 'OclMessage'
[D] oclTypeCS ::= 'OclVoid'

Synthesized attributes
[A] oclTypeCS.ast = OclAny
[B] oclTypeCS.ast = OclInvalid
[C] oclTypeCS.ast = OclMessage
[D] oclTypeCS.ast = OclVoid

Inherited attributes
-- none

Disambiguating rules
-- none

9.4.31(collectionTypeCS)

A typename is either a Classifier, or a collection of some type.
collectionTypeCS ::= collectionTypelentifierCS ‘(‘ typeCS ‘)’

Abstract syntax mapping
typeCS.ast : CollectionType

Synthesized attributes
collectionTypeCS.ast.elementType = typeCS.ast
-- We know that the ‘ast’ is a collectiontype, all we need to state now is which
-- specific collection type it is.
kind = CollectionKind::Set implies collectionTypeCS.ast.oclIsKindOf (SetType)

kind = CollectionKind::OrderedSetimplies collectionTypeCS.ast.oclIsKindOf (OrderedSetType)

Inherited attributes

typeCS.env = collectionTypeCS.env

Disambiguating rules

-- none

9.4.32 tupleTypeCS

This represents a tuple type declaration.
tupleTypeCS ::= ‘Tuple’ ‘(’ variableDeclarationListCS? ‘)’

Abstract syntax mapping

typeCS.ast : TupleType

Synthesized attributes

typeCS.ast =  TupleType::make( variableDeclarationListCS->collect( v | v.asAttribute() ))

Inherited attributes

variableDeclarationListCS.env = tupleTypeCS.env

Disambiguating rules

[106][1] Of all VariableDeclarations the initExpression must be empty and the type must exist.
variableDeclarationListCS.ast->forAll( varDecl | varDecl.initExpression->notEmpty() and varDecl.type->notEmpty() )

9.4.33 variableDeclarationListCS

This production rule represents the formal parameters of a tuple or attribute definition.
variableDeclarationListCS[1] = VariableDeclarationCS
    (‘,’variableDeclarationListCS[2] )?

Abstract syntax mapping

variableDeclarationListCS[1].ast : Sequence( VariableDeclaration )

Synthesized attributes

variableDeclarationListCS[1].ast = Sequence{VariableDeclarationCS.ast}
    ->union(variableDeclarationListCS[2].ast)
Inherited attributes

VariableDeclarationCS.env = variableDeclarationListCS[1].env
variableDeclarationListCS[2].env = variableDeclarationListCS[1].env

Disambiguating rules

-- none

9.4.34 FeatureCallExpCS

A FeatureCallExp expression may have three different productions. Which one is chosen depends on the disambiguating rules defined in each of the alternatives.

[107][A] FeatureCallExpCS ::= OperationCallExpCS
[108][B] FeatureCallExpCS ::= PropertyCallExpCS
[109][C] FeatureCallExpCS ::= NavigationCallExpCS

Abstract syntax mapping

FeatureCallExpCS.ast : FeatureCallExp

Synthesized attributes

The value of this production is the value of its child production.

[A] FeatureCallExpCS.ast = OperationCallExpCS.ast
[B] FeatureCallExpCS.ast = PropertyCallExpCS.ast
[C] FeatureCallExpCS.ast = NavigationCallExpCS.ast

Inherited attributes

[A] OperationCallExpCS.env = FeatureCallExpCS.env
[B] PropertyCallExpCS.env = FeatureCallExpCS.env
[C] NavigationCallExpCS.env = FeatureCallExpCS.env

Disambiguating rules

These are defined in the children.

9.4.35 OperationCallExpCS

An operation call has many different forms. A is used for infix, B for using an object as an implicit collection. C is a straightforward operation call, while D has an implicit source expression. E, F and J are like C, D, and I, with the @pre addition. G covers the static operation call. Rule H is for unary prefix expressions. I and J use pathNameCS to permit qualification of operation names in access to redefined operations.

[111][B] OperationCallExpCS ::= OclExpressionCS '->' simpleNameCS '( argumentsCS? ')' 
[112][C] OperationCallExpCS ::= OclExpressionCS '.' simpleNameCS '( argumentsCS? ')' 
[113][D] OperationCallExpCS ::= simpleNameCS '( argumentsCS? ')' 
[114][E] OperationCallExpCS ::= OclExpressionCS '.' simpleNameCS isMarkedPreCS '( argumentsCS? ')' 
[115][F] OperationCallExpCS ::= simpleNameCS isMarkedPreCS '( argumentsCS? ')'
[116][G] OperationCallExpCS ::= pathNameCS ( argumentsCS )
[117][H] OperationCallExpCS ::= simpleNameCS OclExpressionCS
[118][I] OperationCallExpCS ::= OclExpressionCS . pathNameCS :: simpleNameCS ( argumentsCS )
[119][J] OperationCallExpCS ::= OclExpressionCS . pathNameCS :: isMarkedPreCS ( argumentsCS )

Abstract syntax mapping

OperationCallExpCS.ast : OperationCallExp

Synthesized attributes

-- this rule is for binary operators as `+`, `-`, `*`, etc. It has only one argument.
[A] OperationCallExpCS.ast.arguments  = Sequence{OclExpression2[2].ast}
    OperationCallExpCS.ast.source     = OclExpressionCS[1].ast

9.4.49 Comments
It is possible to include comments anywhere in a text composed according to the above concrete syntax. There will be no mapping of any comments to the abstract syntax. Comments are simply skipped when the text is being parsed. There are two forms of comments, a line comment, and a paragraph comment. The line comment starts with the string '--' and ends with the next newline. The paragraph comment starts with the string '/*' and ends with the string '*/.' Paragraph comments may be nested.

9.5 Environment Definition

The Environment type used in the rules for the concrete syntax is defined according to the following invariants and additional operations. A diagrammatic view can be found in Figure 9.1. Environments can be nested, denoted by the existence of a parent environment. Each environment keeps a list of named elements, that have a name a reference to a ModelElement.

9.5.1 Environment
The definition of Environment has the following invariants and specifications of its operations.

[139][1] The attribute EMPTY_ENV is really just a helper to avoid having to say new Environment (...).

```context Environment
inv EMPTY_ENV_Definition: EMPTY_ENV.namedElements->isEmpty()
```
Find a named element in the current environment, not in its parents, based on a single name.

context Environment::lookupLocal(name : String) : NamedElement
post: result = namedElements->any(v | v.name = name)

Find a named element in the current environment or recursively in its parent environment, based on a single name.

context Environment::lookup(name: String) : ModelElement
post: result = if not lookupLocal(name).oclIsUndefined() then
    lookupLocal(name).referredElement
else
    parent.lookup(name)
endif

Find a named element in the current environment or recursively in its parent environment, based on a path name.

context Environment::lookupPathName(names: Sequence(String)) : ModelElement
post: let firstNamespace : ModelElement = lookupLocal( names->first() ).referredElement
in
    if firstNamespace.oclIsKindOf(Namespace)
        -- indicates a sub namespace of the namespace in which self is present
        then
            result = self.nestedEnvironment().addNamespace(
                firstNamespace ).lookupPathName( names->subSequence(2, names->size()) )
        else
            -- search in surrounding namespace
            result = parent.lookupPathName( names )
    endif

Add a new named element to the environment. Note that this operation is defined as a query operation so that it can be used in OCL constraints.

context Environment::addElement (name : String,
    elem : ModelElement, imp : Boolean) : Environment
pre: -- the name must not clash with names already existing in this environment
    self.lookupLocal(name).oclIsUndefined()
post: result.parent = self.parent and
    result.namedElements->includesAll (self.namedElements) and
    result.namedElements->count (v | v.oclIsNew()) = 1 and
    result.namedElements->forAll (v | v.oclIsNew() implies
        v.name = name and v.referredElement = elem)
    and
    v.mayBeImplicit = imp )

Combine two environments resulting in a new environment. Note that this operation is defined as a query operation so that it can be used in OCL constraints.

context Environment::addEnvironment(env : Environment) : Environment
pre: -- the names must not clash with names already existing in this environment
    env.namedElements->forAll(nm | self.lookupLocal(nm).oclIsUndefined() )
post: result.parent = self.parent and
    result.namedElements = self.namedElements->union(env.namedElements)

Add all elements in the namespace to the environment.

context Environment::addNamespace(ns: Namespace) : Environment
post: result.namedElements = ns.getEnvironmentWithoutParents().namedElements->union(
    self.namedElements)
post: result.parent = self.parent

This operation results in a new environment that has the current one as its parent.

context Environment::nestedEnvironment() : Environment
post: result.namedElements->isEmpty()
post: result.parent = self
post: result.oclIsNew()

[147][9] Lookup a given attribute name of an implicitly named element in the current environment, including its parents.
context Environment::lookupImplicitAttribute(name: String) : Attribute
pre: -- none
post: result = lookupImplicitSourceForAttribute(name).referredElement.oclAsType(Attribute)

[148][10] Lookup the implicit source belonging to a given attribute name in the current environment, including the parents.
context Environment::lookupImplicitSourceForAttribute(name: String) : NamedElement
pre: -- none
post: let foundElement : NamedElement =
    namedElements->select(mayBeImplicit)
    ->any( ne | not ne.getType().lookupAttribute(name).oclIsUndefined() ) in
    result = if foundAttribute.oclIsUndefined() then
        self.parent.lookupImplicitSourceForAttribute(name)
    else
        foundElement
    end

[149][11] Lookup a given association end name of an implicitly named element in the current environment, including its parents.
context Environment::lookupImplicitAssociationEnd(name: String) : AssociationEnd
pre: -- none
post: let foundAssociationEnd : AssociationEnd =
    namedElements->select(mayBeImplicit)
    ->any( ne | not ne.getType().lookupAssociationEnd(name).oclIsUndefined() ) in
    result = if foundAssociationEnd.oclIsUndefined() then
        self.parent.lookupImplicitAssociationEnd(name)
    else
        foundAssociationEnd
    end

[150][12] Lookup an operation of an implicitly named element with given name and parameter types in the current environment, including its parents.
context Environment::lookupImplicitOperation(name: String, params : Sequence(Classifier)) : Operation
pre: -- none
post: let foundOperation : Operation =
    namedElements->select(mayBeImplicit)
    ->any( ne | not ne.getType().lookupOperation(name, params).oclIsUndefined() ) in
    result = if foundOperation.oclIsUndefined() then
        self.parent.lookupImplicitOperation(name)
    else
        foundOperation
    end

In OCL 2.0 and 2.2 a reserved word could be used as a name after prefixing it with an underscore. Therefore, for compatibility, a lookup of simpleNameCS[A] name with a leading underscore may need to be looked up twice. The symbol is first looked up in the meta-model with the underscore prefix, and if no value is found, the symbol is looked up gain without the underscore prefix.

A double lookup is not required for a simpleNameCS[B] or [C] name (an underscore-prefixed singly quoted string).
The second lookup after removing the underscore prefix is deprecated in OCL 2.3 and will be discontinued in OCL 3.0. Tool implementors should provide a warning message for this deprecated usage.

### 9.5.2 NamedElement

A named element is a modelelement that is referred to by a name. A modelelement itself has a name, but this is not always the name that is used to refer to it.

The operation getType() returns the type of the referred modelelement.

```plaintext
context NamedElement::getType() : Classifier
pre: -- none
post: referredElement.oclIsKindOf(VariableDeclaration) implies
      result = referredElement.oclAsType(VariableDeclaration).type
post: referredElement.oclIsKindOf(Classifier) implies
      result = referredElement
post: referredElement.oclIsKindOf(State) implies
      result = -- TBD: when aligning with UML 2.0 Infrastructure
```

### 9.5.3 Namespace

The following additional operation returns the information of the contents of the namespace in the form of an Environment object, where Environment is the class defined in this clause. Note that the parent association of Environment is not filled.

Because the definition of this operation is completely dependent on the UML metamodel, and this model will be considerably different in the 2.0 version, the definition is left to be done.

```plaintext
context Namespace::getEnvironmentWithoutParents() : Environment
post: self.isTypeOf(Classifier) implies -- TBD when aligning with UML 2.0 Infrastructure
     -- include all class features and contained classifiers
post: self.isTypeOf(Package) implies -- TBD when aligning with UML 2.0 Infrastructure
     -- include all classifiers and subpackages
post: self.isTypeOf(StateMachine) implies -- TBD when aligning with UML 2.0 Infrastructure
     -- include all states
post: self.isTypeOf(Subsystem) implies -- TBD when aligning with UML 2.0 Infrastructure
     -- include all classifiers and subpackages

The following operation returns an Environment that contains a reference to its parent environment, which is itself created by this operation by means of a recursive call, and therefore contains a parent environment too.

```plaintext
context Namespace::getEnvironmentWithParents() : Environment
post: result.NamedElements = self.getEnvironmentWithoutParents()
post: if self.namespace->notEmpty() -- this namespace has an owning namespace
      then result.parent = self.namespace.getEnvironmentWithParents()
      else result.parent = invalid
     endif
```

### 9.6 Concrete to Abstract Syntax Mapping

The mapping from concrete to abstract syntax is described as part of the grammar. It is described by adding a synthesized attribute `ast` to each production that has the corresponding metaclass from the abstract syntax as its type. This allows the mapping to be fully formalized within the attribute grammar formalism.
9.7 Abstract Syntax to Concrete Syntax Mapping

It is often useful to have a defined mapping from the abstract syntax to the concrete syntax. This mapping can be defined by applying the production rules in sub clause 9.4 from left to right. As a general guideline nothing will be implicit (for example, implicit collect, implicit use of object as set) and all iterator variables will be filled in completely. The mapping is not formally defined in this document but should be obvious.
10 Semantics Described Using UML

10.1 Introduction

This clause describes the semantics of the OCL using the UML itself to describe the semantic domain and the mapping between semantic domain and abstract syntax.

In sub clause 8.3, The Expressions Package an OCL expression is defined as: “an expression that can be evaluated in a given environment,” and in 8.2, The Types Package it is stated that an “evaluation of the expression yields a value.” The ‘meaning’ (semantics) of an OCL expression, therefore, can be defined as the value yielded by its evaluation in a given environment.

To specify the semantics of OCL expressions we need to define two things: (1) the set of possible values that evaluations of expressions may yield, and (2) evaluations and their environment. The set of possible values is called the semantic domain. The set of evaluations together with their associations with the concepts from the abstract syntax represent the mapping from OCL expressions to values from the semantic domain. Together the semantic domain and the evaluations with their environment will be called domain in this clause.

The semantic domain is described in the form of a UML package, containing a UML class diagram, classes, associations, and attributes. The real semantic domain is the (infinite) set of instances that can be created according to this class diagram. To represent the evaluation of the OCL expressions in the semantic domain a second UML package is used. In it, a set of so-called evaluation classes is defined (in short eval). Each evaluation class is associated with a value (its result value), and a name space environment that binds names to values. Note that the UML model comprising both packages, resides on layer 1 of the OMG 4-layered architecture, while the abstract syntax defined in Clause 8 (“Abstract Syntax”), resides on layer 2.

The semantics of an OCL expression is given by association: each value defined in the semantic domain is associated with a type defined in the abstract syntax, each evaluation is associated with an expression from the abstract syntax. The value yielded by an OCL expression in a given environment, its ‘meaning’ is the result value of its evaluation within a certain name space environment. The semantics are also described in the form of a UML package called “AS-Domain-Mapping.” Note that this package links the domain on layer 1 of the OMG 4-layered architecture with the abstract syntax on layer 2. The AS-Domain-Mapping package itself cannot be positioned in one of the layers of the OMG 4-layered architecture. Note also that this package contains associations only, no new classes are defined.

Figure 10.1 shows how the packages defined in this clause relate to each other, and to the packages from the abstract syntax.
The Domain package describes the values and evaluations. It is subdivided into two subpackages:

- The Values package describes the semantic domain. It shows the values OCL expressions may yield as result.
- The Evaluations package describes the evaluations of OCL expressions. It contains the rules that determine the result value for a given expression.

The AS-Domain-Mapping package describes the associations of the values and evaluations with elements from the abstract syntax. It is subdivided into two subpackages:

- The Type-Value package contains the associations between the instances in the semantics domain and the types in the abstract syntax.
- The Expression-Evaluation package contains the associations between the evaluation classes and the expressions in the abstract syntax.

## 10.2 The Values Package

OCL is an object language. A value can be either an object, which can change its state in time, or a data type, which can not change its state. The model in Figure 10.2 shows the values that form the semantic domain of an OCL expression. The basic type is the Value, which includes both objects and data values. There is a special subtype of Value called UndefinedValue, which is used to represent the undefined value for any Type in the abstract syntax.

Figure 10.3 shows a number of special data values, the collection and tuple values. To distinguish between instances of the Set, Bag, and Sequence types defined in the standard library, and the classes in this package that represent instances in the semantic domain, the names SetValue, BagValue, and SequenceValue are used, instead of SetTypeValue, BagTypeValue, and SequenceTypeValue.
Figure 10.2 - The kernel values in the semantic domain

The value resulting from an ocl message expression is shown in Figure 10.4. It links an ocl message value to the snapshot of an object.

### 10.2.1 Definitions of Concepts for the Values Package

The sub clause lists the definitions of concepts in the Values package in alphabetical order.

#### 10.2.1.1 BagTypeValue

A bag type value is a collection value that is a multiset of values, where each value may occur multiple times in the bag. The values are unordered. In the metamodel, this list of values is shown as an association from CollectionValue (a generalization of BagTypeValue) to Element.

#### 10.2.1.2 CollectionValue

A collection value is a list of values. In the metamodel, this list of values is shown as an association from CollectionValue to Element.

**Associations**

- `elements`: The values of the elements in a collection.

#### 10.2.1.3 DomainElement

A domain element is an element of the domain of OCL expressions. It is the generic superclass of all classes defined in this clause, including Value and OclExpEval. It serves the same purpose as ModelElement in the UML meta model.
Figure 10.3 - The collection and tuple values in the semantic domain

10.2.1.4 Element

An element represents a single component of a tuple value, or collection value. An element has an index number and a value. The purpose of the index number is to identify uniquely the position of each element within the enclosing value, when it is used as an element of a SequenceValue.

10.2.1.5 LocalSnapshot

A local snapshot is a domain element that holds for one point in time the subvalues of an object value. It is always part of an ordered list of local snapshots of an object value, which is represented in the metamodel by the associations pred, succ, and history. An object value may also hold a sequence of OclMessageValues, which the object value has sent, and a sequence of OclMessageValues, which the object value has received. Both sequences can change in time, therefore they are included in a local snapshot. This is represented by the associations in the metamodel called inputQ, and outputQ.

A local snapshot has two attributes, isPost and isPre, that indicate whether this snapshot is taken at postcondition or precondition time of an operation execution. Within the history of an object value it is always possible to find the local snapshot at precondition time that corresponds with a given snapshot at postcondition time. The association pre (shown in Figure 10.3) is redundant, but added for convenience.
Associations

bindings  The set of name value bindings that hold the changes in time of the subvalues of the associated object value.

outputQ  The sequence of OclMessageValues that the associated ObjectValue at the certain point in time has sent, and are not yet put through to their targets.

inputQ  The sequence of OclMessageValues that the associated ObjectValue at the certain point in time has received, but not yet dealt with.

pred  The predecessor of this local snapshot in the history of an object value.

succ  The successor of this local snapshot in the history of an object value.

pre  If this snapshot is a snapshot at postcondition time of a certain operation execution, then pre is the associated snapshot at precondition time of the same operation in the history of an object value.

10.2.1.6 NameValueBinding

A name value binding is a domain element that binds a name to a value.

10.2.1.7 ObjectValue

An object value is a value that has an identity, and a certain structure of subvalues. Its subvalues may change over time, although the structure remains the same. Its identity may not change over time. In the metamodel, the structure is shown as a set of NameValueBindings. Because these bindings may change over time, the ObjectValue is associated with a sequence of LocalSnapshots that hold a set of NameValueBindings at a certain point in time.

Associations

history  The sequence of local snapshots that hold the changes in time of the subvalues of this object value.
10.2.1.8 **OclMessageValue**

An ocl message value is a value that has as target and as source an object value. An ocl message value has a number of attributes. The name attribute corresponds to the *name* of the operation called, or signal sent. The *isSyncOperation*, *isAsyncOperation*, and *isSignal* attributes indicate respectively whether the message corresponds to a synchronous operation, an asynchronous operation, or a signal.

**Associations**

- **arguments**: A sequence of name value bindings that hold the arguments of the message from the source to the target.
- **source**: The object value that has sent this signal.
- **target**: The object value for which this signal has been intended.
- **returnMessage**: The ocl message value that holds the values of the result and out parameters of a synchronous operation call in its arguments. Is only present if this message represents a synchronous operation call.

10.2.1.9 **OclVoidValue**

An undefined value is a value that represents void or undefined for any type.

10.2.1.10 **PrimitiveValue**

A primitive value is a predefined static value, without any relevant substructure (i.e., it has no parts).
10.2.1.11 SequenceTypeValue
A sequence type value is a collection value that is a list of values where each value may occur multiple times in the sequence. The values are ordered by their position in the sequence. In the metamodel, this list of values is shown as an association from CollectionValue (a generalization of SequenceTypeValue) to Element. The position of an element in the list is represented by the attribute indexNr of Element.

10.2.1.12 SetTypeValue
A set type value is a collection value that is a set of elements where each distinct element occurs only once in the set. The elements are not ordered. In the metamodel, this list of values is shown as an association from CollectionValue (a generalization of SetTypeValue) to Element.

10.2.1.13 StaticValue
A static value is a value that will not change over time.¹

10.2.1.14 TupleValue
A tuple value (also known as record value) combines values of different types into a single aggregate value. The components of a tuple value are described by tuple parts each having a name and a value. In the metamodel, this is shown as an association from TupleValue to NameValueBinding.

Associations

elements The names and values of the elements in a tuple value.

10.2.1.15 Value
A part of the semantic domain.

10.2.2 Well-formedness Rules for the Values Package

10.2.2.1 BagTypeValue
No additional well-formedness rules.

10.2.2.2 CollectionValue
No additional well-formedness rules.

10.2.2.3 DomainElement
No additional well-formedness rules.

¹ As StaticValue is the counterpart of the DataType concept in the abstract syntax, the name DataValue would be preferable. StaticValue is used for historical reasons concerning past versions of UML.
10.2.2.4 Element
No additional well-formedness rules.

10.2.2.5 EnumValue
No additional well-formedness rules.

10.2.2.6 LocalSnapshot
[151][1] Only one of the attributes \textit{isPost} and \textit{isPre} may be true at the same time.

\begin{verbatim}
context LocalSnapshot
inv: isPost implies isPre = false
inv: isPre implies isPost = false
\end{verbatim}

[152][2] Only if a snapshot is a postcondition snapshot will it have an associated precondition snapshot.

\begin{verbatim}
context LocalSnapshot
inv: isPost implies pre->size() = 1
inv: not isPost implies pre->size() = 0
inv: self.pre->size() = 1 implies self.pre.isPre = true
\end{verbatim}

10.2.2.7 NameValueBinding
No additional well-formedness rules.

10.2.2.8 ObjectValue
[153][1] The history of an object is ordered. The first element does not have a predecessor, the last does not have a successor.

\begin{verbatim}
context ObjectValue
inv: history->oclIsTypeOf( Sequence(LocalSnapShot) )
inv: history->last().succ->size = 0
inv: history->first().pre->size = 0
\end{verbatim}

10.2.2.9 OclMessageValue
[154][1] Only one of the attributes \textit{isSyncOperation}, \textit{isAsyncOperation}, and \textit{isSignal} may be true at the same time.

\begin{verbatim}
context OclMessageValue
inv: isSyncOperation implies isAsyncOperation = false and isSignal = false
inv: isAsyncOperation implies isSyncOperation = false and isSignal = false
inv: isSignal implies isSyncOperation = false and isAsyncOperation = false
\end{verbatim}

[155][2] The return message is only present if, and only if, the ocl message value is a synchronous operation call.

\begin{verbatim}
context OclMessageValue
inv: isSyncOperation implies returnMessage->size() = 1
inv: not isSyncOperation implies returnMessage->size() = 0
\end{verbatim}

10.2.2.10 OclVoidValue
[156] No additional well-formedness rules.

10.2.2.11 PrimitiveValue
No additional well-formedness rules.
10.2.2.12 SequenceTypeValue

[157][1] All elements belonging to a sequence value have unique index numbers.

```plaintext
self.element->isUnique(e : Element | e.indexNr)
```

10.2.2.13 SetTypeValue

[158][1] All elements belonging to a set value have unique values.

```plaintext
self.element->isUnique(e : Element | e.value)
```

10.2.2.14 StaticValue

No additional well-formedness rules.

10.2.2.15 TupleValue

[159][1] All elements belonging to a tuple value have unique names.

```plaintext
self.elements->isUnique(e : Element | e.name)
```

10.2.2.16 Value

No additional well-formedness rules.

10.2.3 Additional Operations for the Values Package

10.2.3.1 LocalSnapshot

[160][1] The operation `allPredecessors` returns the collection of all snapshots before a snapshot, `allSuccessors` returns the collection of all snapshots after a snapshot.

```plaintext
context LocalSnapshot
def: let allPredecessors() : Sequence(LocalSnapshot) =
   if pred->notEmpty then
      pred->union(pred.allPredecessors())
   else
      Sequence {}
   endif
def: let allSuccessors() : Sequence(LocalSnapshot) =
   if succ->notEmpty then
      succ->union(succ.allSuccessors())
   else
      Sequence {}
   endif
```

10.2.3.2 ObjectValue

[161][1] The operation `getCurrentValueOf` results in the value that is bound to the `name` parameter in the bindings of the latest snapshot in the history of an object value. Note that the value may be the UndefinedValue.
context ObjectValue::getCurrentValueOf(n: String): Value
pre: -- none
post: result = history->last().bindings->any(name = n).value

[162][2] The operation outgoingMessages results in the sequence of OclMessageValues that have been in the output queue of the object between the last postcondition snapshot and its associated precondition snapshot.

context OclExpEval::outgoingMessages() : Sequence( OclMessageValue )
pre: -- none
post:
let end: LocalSnapshot =
  history->last().allPredecessors()->select( isPost = true )->first() in
let start: LocalSnapshot = end.pre in
let inBetween: Sequence( LocalSnapshot ) =
  start.allSuccessors()->excluding( end.allSuccessors())->including( start ) in
result = inBetween.outputQ->iterate (
  -- creating a sequence with all elements present once
  m : oclMessageValue;
  res: Sequence( OclMessageValue ) = Sequence{}
  | if not res->includes( m )
  then res->append( m )
  else res
  endif )
endif

10.2.3.3 TupleValue

[163][1] The operation getValueOf results in the value that is bound to the name parameter in the tuple value.

context TupleValue::getValueOf(n: String): Value
pre: -- none
post: result = elements->any(name = n).value

10.2.4 Overview of the Values Package

Figure 10.5 shows an overview of the inheritance relationships between the classes in the Values package.
10.3 The Evaluations Package

This sub clause defines the evaluations of OCL expressions. The evaluations package is a mirror image of the expressions package from the abstract syntax. Figure 10.6 shows how the environment of an OCL expression evaluation is structured. The environment is determined by the placement of the expression within the UML model as discussed in Clause 12 ("The Use of Ocl Expressions in UML Models"). The calculation of the environment is done in the ExpressionInOclEval, which will be left undefined here.
Figure 10.6 shows the core part of the Evaluations package. In Figure 10.7 the various subtypes of OclExpEval are defined. An OclExpEval always has a result value, and a name space that binds names to values.

Most of the OCL expressions can be simply evaluated, i.e., their value can be determined based on a non-changing set of name value bindings. Operation call expressions, however, need the execution of the called operation. The semantics of the execution of an operation will be defined in the UML infrastructure. For our purposes it is enough to assume that an operation execution will add to the environment of an OCL expression the name ‘result’ bound to a certain value. In order not to become tangled in a mix of terms, the term evaluation is used in the following to denote both the ‘normal’ OCL evaluations and the executions of operation call expressions.

In Section 10.3.1.13, “Model PropertyCall Evaluations,” on page 119 to Section 10.3.1.26, “Let Expressions,” on page 124 special subclasses of OclExpEval will be defined.

10.3.1 Definitions of Concepts for the Evaluations Package

This sub clause lists the definitions of concepts in the Evaluations package in alphabetical order.

10.3.1.1 EvalEnvironment

An EvalEnvironment is a set of NameValueBindings that form the environment in which an OCL expression is evaluated. An EvalEnvironment has three operations that are defined in “Additional Operations of the Evaluations Package.”
Associations

10.3.1.2 IterateExpEval
An IterateExpEval is an expression evaluation that evaluates its body expression for each element of a collection value, and accumulates a value in a result variable. It evaluates an IterateExp.

10.3.1.3 IteratorExpEval
An IteratorExp is an expression evaluation that evaluates its body expression for each element of a collection.

10.3.1.4 ExpressionInOclEval
An ExpressionInOclEval is an evaluation of the context of an OCL expression. It is the counterpart in the domain of the ExpressionInOcl metaclass defined in Clause 12 (“The Use of Ocl Expressions in UML Models”). It is merely included here to be able to determine the environment of an OCL expression.

10.3.1.5 LiteralExpEval
A Literal expression evaluation is an evaluation of a Literal expression.

10.3.1.6 LoopExpEval
A loop expression evaluation is an evaluation of a Loop expression.

Associations

bodyEvals The oclExpEvaluations that represent the evaluation of the body expression for each element in the source collection.

iterators The names of the iterator variables in the loop expression.

10.3.1.7 ModelPropertyCallExpEval
A model property call expression evaluation is an evaluation of a ModelPropertyCallExp. In Figure 10.8 the various subclasses of ModelPropertyCallExpEval are shown.

Operations

atPre The atPre operation returns true if the property call is marked as being evaluated at pre-condition time.

10.3.1.8 OclExpEval
An ocl expression evaluation is an evaluation of an OclExpression. It has a result value, and it is associated with a set of name-value bindings called environment. These bindings represent the values that are visible for this evaluation, and the names by which they can be referenced. A second set of name-value bindings is used to evaluate any sub expression for which the operation atPre returns true, called beforeEnvironment.
Note that as explained in Clauses 9 (“Concrete Syntax”) and 12 (“The Use of Ocl Expressions in UML Models”) these bindings need to be established, based on the placement of the OCL expression within the UML model. A binding for an invariant will not need the beforeEnvironment, and it will be different from a binding of the same expression when used as precondition.

**Associations**

environment The set of name value bindings that is the context for this evaluation of an ocl expression.

beforeEnvironment The set of name value bindings at the precondition time of an operation, to evaluate any sub expressions of type ModelPropertyCallExp for which the operation atPre returns true.

resultValue The value that is the result of evaluating the OclExpression.

### 10.3.1.9 OclMessageExpEval

An ocl message expression evaluation is defined in “Ocl Message Expression Evaluations” on page 121, but included in this diagram for completeness.

### 10.3.1.10 PropertyCallExpEval

A property call expression evaluation is an evaluation of a PropertyCallExp.

**Associations**

source The result value of the source expression evaluation is the instance that performs the property call.

### 10.3.1.11 VariableDeclEval

A variable declaration evaluation represents the evaluation of a variable declaration. Note that this is not a subtype of OclExpEval, therefore it has no resultValue.

**Associations**

name The name of the variable.

initExp The value that will be initially bound to the name of this evaluation.

### 10.3.1.12 VariableExpEval

A variable expression evaluation is an evaluation of a VariableExp, which in effect is the search of the value that is bound to the variable name within the environment of the expression.

**Associations**

variable The name that refers to the value that is the result of this evaluation.
10.3.1.13 Model PropertyCall Evaluations

The subtypes of ModelPropertyCallExpEval are shown in Figure 10.8, and are defined in this sub clause in alphabetical order.

10.3.1.14 AssociationClassCallExpEval

An association end call expression evaluation is an evaluation of an AssociationClassCallExp, which in effect is the search of the value that is bound to the associationClass name within the expression environment.

Associations

referredAssociationClass  The name of the AssociationClass to which the corresponding AssociationClassCallExp is a reference.

10.3.1.15 AssociationEndCallExpEval

An association end call expression evaluation is an evaluation of an AssociationEndCallExp, which in effect is the search of the value that is bound to the associationEnd name within the expression environment.
Associations

referredAssociationEnd    The name of the AssociationEnd to which the corresponding NavigationCallExp is a reference.

10.3.1.16 AttributeCallExpEval
An attribute call expression evaluation is an evaluation of an AttributeCallExp, which in effect is the search of the value that is bound to the attribute name within the expression environment.

Associations

referredAttribute    The name of the Attribute to which the corresponding AttributeCallExp is a reference.

10.3.1.17 NavigationCallExpEval
A navigation call expression evaluation is an evaluation of a NavigationCallExp.

Associations

navigationSource    The name of the AssociationEnd of which the corresponding NavigationCallExp is the source.

10.3.1.18 OperationCallExpEval
An operation call expression evaluation is an evaluation of an OperationCallExp.

Associations

arguments    The arguments denote the arguments to the operation call. This is only useful when the operation call is related to an Operation that takes parameters.

referredOperation    The name of the Operation to which this OperationCallExp is a reference. This is an Operation of a Classifier that is defined in the UML model.

10.3.1.19 If Expression Evaluations
If expression evaluations are shown in Figure 10.9 and defined in this sub clause.

Figure 10.9 - Domain model for if expression
10.3.1.20 IfExpEval

An IfExpEval is an evaluation of an IfExp.

**Associations**

- condition: The OclExpEval that evaluates the condition of the corresponding IfExpression.
- thenExpression: The OclExpEval that evaluates the thenExpression of the corresponding IfExpression.
- elseExpression: The OclExpEval that evaluates the elseExpression of the corresponding IfExpression.

10.3.1.21 Ocl Message Expression Evaluations

Ocl message expressions are used to specify the fact that an object has, or will send some message to another object at some moment in time. Ocl message expression evaluations are shown in Figure 10.10, and defined in this sub clause.

![Figure 10.10 - Domain model for message evaluation](image)

10.3.1.22 OclMessageArgEval

An ocl message argument evaluation is an evaluation of an OclMessageArg. It represents the evaluation of the actual parameters to the Operation or Signal. An argument of a message expression is either an ocl expression, or a variable declaration.
10.3.1.23 OclMessageExpEval

An ocl message expression evaluation is an evaluation of an OclMessageExp. The only demand we can put on the ocl message expression is that the OclMessageValue it represents (either an operation call, or a UML signal), has been at some time between ‘now’ and a reference point in time in the output queue of the sending instance. The ‘now’ timepoint is the point in time at which this evaluation is performed. This point is represented by the environment link of the OclMessageExpEval (inherited from OclExpEval).

Associations

target The OclExpEval that represents the evaluation of the target instance or instances on which the action is performed.

arguments The OclMessageArgEvals that represent the evaluation of the actual parameters to the Operation or Message.

10.3.1.24 UnspecifiedValueExpEval

An unspecified value expression evaluation is an evaluation of an UnSpecifiedValueExp. It results in a randomly picked instance of the type of the expression.

10.3.1.25 Literal Expression Evaluations

This sub clause defines the different types of literal expression evaluations in OCL, as shown in Figure 10.11. Again it is a complete mirror image of the abstract syntax.
Figure 10.11 - Domain model for literal expressions

**BooleanLiteralExpEval**
A boolean literal expression evaluation represents the evaluation of a boolean literal expression.

**CollectionItemEval**
A collection item evaluation represents the evaluation of a collection item.

**CollectionLiteralExpEval**
A collection literal expression evaluation represents the evaluation of a collection literal expression.

**CollectionLiteralPartEval**
A collection literal part evaluation represents the evaluation of a collection literal part.

**CollectionRangeEval**
A collection range evaluation represents the evaluation of a collection range.

**EnumLiteralExpEval**
An enumeration literal expression evaluation represents the evaluation of an enumeration literal expression.

**IntegerLiteralExpEval**
A integer literal expression evaluation represents the evaluation of a integer literal expression.

**NumericLiteralExpEval**
A numeric literal expression evaluation represents the evaluation of a numeric literal expression.
**ISO/IEC 19507:2012(E)**

**PrimitiveLiteralExpEval**
A primitive literal expression evaluation represents the evaluation of a primitive literal expression.

**RealLiteralExpEval**
A real literal expression evaluation represents the evaluation of a real literal expression.

**StringLiteralExpEval**
A string literal expression evaluation represents the evaluation of a string literal expression.

**TupleLiteralExpEval**
A tuple literal expression evaluation represents the evaluation of a tuple literal expression.

**TupleLiteralExpPartEval**
A tuple literal expression part evaluation represents the evaluation of a tuple literal expression part.

**UnlimitedNaturalLiteralExpEval**
An unlimited natural literal expression evaluation represents the evaluation of an unlimited natural literal expression.

**10.3.1.26 Let Expressions**
Let expressions define new variables. The structure of the let expression evaluation is shown in Figure 10.12.

![Diagram of Let expression evaluation](image)

**LetExpEval**
A Let expression evaluation is an evaluation of a Let expression that defines a new variable with an initial value. A Let expression evaluation changes the environment of the *in* expression evaluation.
10.3.2 Well-formedness Rules of the Evaluations Package

The metaclasses defined in the evaluations package have the following well-formedness rules. These rules state how the result value is determined. This defines the semantics of the OCL expressions.

10.3.2.1 AssociationClassCallExpEval

[164][1] The result value of an association class call expression is the value bound to the name of the association class to which it refers. Note that the determination of the result value when qualifiers are present is specified in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package. The operation getCurrentValueOf is an operation defined on ObjectValue in 10.2.3, Additional Operations for the Values Package.

\[
\text{context AssociationClassCallExpEval inv:} \\
\text{qualifiers->size = 0 implies} \\
\text{resultValue = source.resultValue.getCurrentValueOf(referredAssociationClass.name)}
\]

10.3.2.2 AssociationEndCallExpEval

[165][1] The result value of an association end call expression is the value bound to the name of the association end to which it refers. Note that the determination of the result value when qualifiers are present is specified in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.

\[
\text{context AssociationEndCallExpEval inv:} \\
\text{qualifiers->size = 0 implies} \\
\text{resultValue = source.resultValue.getCurrentValueOf(referredAssociationEnd.name)}
\]

10.3.2.3 AttributeCallExpEval

[166][1] The result value of an attribute call expression is the value bound to the name of the attribute to which it refers.

\[
\text{context AttributeCallExpEval inv:} \\
\text{resultValue = if source.resultValue->oclIsTypeOf( ObjectValue) then} \\
\text{source.resultValue->oclAsType( ObjectValue )} \\
\text{.getCurrentValueOf(referredAttribute.name)} \\
\text{else -- must be a tuple value} \\
\text{source.resultValue->oclAsType( TupleValue )} \\
\text{.getValueOf(referredAttribute.name)} \\
\text{endif}
\]

10.3.2.4 BooleanLiteralExpEval

No extra well-formedness rules. The manner in which the resultValue is determined is given in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.
10.3.2.5 CollectionItemEval

[167][1] The value of a collection item is the result value of its item expression. The environment of this item expression is equal to the environment of the collection item evaluation.

context CollectionItemEval
inv: element = item.resultValue
inv: item.environment = self.environment

10.3.2.6 CollectionLiteralExpEval

[168][1] The environment of its parts is equal to the environment of the collection literal expression evaluation.

context CollectionLiteralExpEval
inv: parts->forAll( p | p.environment = self.environment )

[169][2] The result value of a collection literal expression evaluation is a collection literal value, or one of its subtypes.

context CollectionLiteralExpEval
inv:
resultValue.oclIsKindOf( CollectionValue )

[170][3] The number of elements in the result value is equal to the number of elements in the collection literal parts, taking into account that a collection range can result in many elements.

context CollectionLiteralExpEval
inv:
resultValue.elements->size() = parts->collect( element )->size()->sum()

[171][4] The elements in the result value are the elements in the collection literal parts, taking into account that a collection range can result in many elements.

context CollectionLiteralExpEval
inv:
let allElements = parts->collect( element )->flatten() in
Sequence{1..allElements->size()}->forAll( i: Integer |
resultValue.elements->at(i).name = ii and
resultValue.elements->at(i).value = allElements->at(i) and
self.kind = CollectionKind::Sequence implies
resultValue.elements->at(i).indexNr = i )

10.3.2.7 CollectionLiteralPartEval

No extra well-formedness rules. The manner in which its value is determined is given by its subtypes.

10.3.2.8 CollectionRangeEval

[172][1] The value of a collection range is the range of integer numbers between the result value of its first expression and its last expression.

context CollectionRangeEval
inv: element.oclIsTypeOf( Sequence(Integer) ) and
element = getRange( first->oclAsType(Integer), last->oclAsType(Integer) )

10.3.2.9 EnumLiteralExpEval

No extra well-formedness rules.

10.3.2.10 EvalEnvironment

[173][1] All names in a name space must be unique.
context EvalEnvironment inv:
  bindings->collect(name)->forall( name: String | bindings->collect(name)->isUnique(name))

10.3.2.11 ExpressionInOclEval

No extra well-formedness rules.

10.3.2.12 IfExpEval

[174][1] The result value of an if expression is the result of the thenExpression if the condition is true, else it is the result of the elseExpression.

context IfExpEval inv:
  resultValue = if condition then thenExpression.resultValue else elseExpression.resultValue

[175][2] The environment of the condition, thenExpression and elseExpression are equal to the environment of the if expression.

context IfExpEval
  inv: condition.environment = environment
  inv: thenExpression.environment = environment
  inv: elseExpression.environment = environment

10.3.2.13 IntegerLiteralExpEval

No extra well-formedness rules. The manner in which the resultValue is determined is given in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.

10.3.2.14 IterateExpEval

[176][1] All sub evaluations have a different environment. The first sub evaluation will start with an environment in which all iterator variables are bound to the first element of the source, plus the result variable that is bound to the init expression of the variable declaration in which it is defined.

context IterateExpEval
  inv: let bindings: Sequence( NameValueBindings ) =
    iterators->collect( i | NameValueBinding( i.varName, source->asSequence()->first() ) )
  in
    bodyEvals->at(1).environment = self.environment->addAll( bindings )
    ->add( NameValueBinding( result.name, result.initExp.resultValue ) )

[177][2] The environment of any sub evaluation is the same environment as the one from its previous sub evaluation, taking into account the bindings of the iterator variables, plus the result variable which is bound to the result value of the last sub evaluation.

inv: let SS: Integer = source.value->size()
in if iterators->size() = 1 then
  Sequence{2..SS}->forall( i: Integer |
    bodyEvals->at(i).environment = bodyEvals->at(i-1).environment
    ->replace( NameValueBinding( iterators->at(1).varName, source.value->asSequence()->at(i)) )
    ->replace( NameValueBinding( result.varName, bodyEvals->at(i-1).resultValue ) )
  )
else -- iterators->size() = 2
  Sequence{2..SS*SS}->forall( i: Integer |
    bodyEvals->at(i).environment = bodyEvals->at(i-1).environment
  )
->replace( NameValueBinding( iterators->at(1).varName,  
          source->asSequence()->at(i.div(SS) + 1) ))
->replace( NameValueBinding( iterators->at(2).varName,  
          source.value->asSequence()->at(i.mod(SS))))
->replace( NameValueBinding( result.varName,  
          bodyEvals->at(i-1).resultValue )))

endif

[178][3] The result value of an IteratorExpEval is the result of the last of its body evaluations.

context IteratorExpEval
inv: resultValue = bodyEvals->last().resultValue

10.3.2.15 IteratorExpEval

The *IteratorExp* in the abstract syntax is merely a placeholder for the occurrence of one of the predefined iterator
expressions in the standard library (see Clause 11 “The OCL Standard Library”). These predefined iterator expressions
are all defined in terms of an iterate expression. The semantics defined for the iterate expression are sufficient to define
the iterator expression. No well-formedness rules for IteratorExpEval are defined.

10.3.2.16 LetExpEval

[179][1] A let expression results in the value of its *in* expression.

context LetExpEval inv:
resultValue = in.resultValue

[180][2] A let expression evaluation adds a name value binding that binds the *variable* to the value of its *initExpression*, to
the environment of its *in* expression.

context LetExpEval
inv: in.environment = self.environment
->add( NameValueBinding( variable.varName, variable.initExpression.resultValue ))

[181][3] The environment of the *initExpression* is equal to the environment of this Let expression evaluation.

context LetExpEval
inv: initExpression.environment = self.environment

10.3.2.17 LiteralExpEval

No extra well-formedness rules.

10.3.2.18 LoopExpEval

The result value of a loop expression evaluation is determined by its subtypes.

[182][1] There is an OclExpEval (a sub evaluation) for combination of values for the iterator variables. Each iterator variable
will run through every element of the source collection.

[183]
context LoopExpEval
inv: bodyEvals->size() =
   if iterators->size() = 1 then
      source.value->size()
   else -- iterators->size() = 2
      source.value->size() * source.value->size()
   endif
[184][2] All sub evaluations (in the sequence bodyEvals) have a different environment. The first sub evaluation will start with an environment in which all iterator variables are bound to the first element of the source. Note that this is an arbitrary choice, one could easily start with the last element of the source, or any other combination.

```
context LoopExpEval
inv: let bindings: Sequence( NameValueBindings ) =
    iterators->collect( i |
        NameValueBinding( i.varName, source->asSequence()->first() )
    )
in
    bodyEvals->at(1).environment = self.environment->addAll( bindings )
```

[185][3] All sub evaluations (in the sequence bodyEvals) have a different environment. The environment is the same environment as the one from the previous bodyEval, where the iterator variable or variables are bound to the subsequent elements of the source.

```
context LoopExpEval
inv: let SS: Integer = source.value->size()
in if iterators->size() = 1 then
    Sequence{2..SS}->forAll( i: Integer |
        bodyEvals->at(i).environment = bodyEvals->at(i-1).environment
        ->replace( NameValueBinding( iterators->at(1).varName, source.value->asSequence()->at(i) ))
    )
else -- iterators->size() = 2
    Sequence{2..SS*SS}->forAll( i: Integer |
        bodyEvals->at(i).environment = bodyEvals->at(i-1).environment
        ->replace( NameValueBinding( iterators->at(1).varName, source.value->asSequence()->at(i.div(SS) + 1) ))
        ->replace( NameValueBinding( iterators->at(2).varName, source.value->asSequence()->at(i.mod(SS)) ))
    )
endif
```

10.3.2.19 ModelPropertyCallExpEval

Result value is determined by its subtypes.

[186][1] The environment of a ModelPropertyCall expression is equal to the environment of its source.

```
context ModelPropertyCallExpEval inv:
    environment = source.environment
```

10.3.2.20 NavigationCallExpEval

[187][1] When the navigation call expression has qualifiers, the result value is limited to those elements for which the qualifier value equals the value of the attribute.

```
-- To be done.
```

10.3.2.21 NumericLiteralExpEval

No extra well-formedness rules. Result value is determined by its subtypes.

10.3.2.22 OclExpEval

The result value of an ocl expression is determined by its subtypes.

[188][1] The environment of an OclExpEval is determined by its context, i.e., the ExpressionInOclEval.
10.3.2.23 OclMessageExpEval

[190][1] The result value of an ocl message expression is an ocl message value.

context OclMessageExpEval
inv: resultValue->isTypeOf( OclMessageValue )

[191][2] The result value of an ocl message expression is the sequence of the outgoing messages of the ‘self’ object that matches the expression. Note that this may result in an empty sequence when the expression does not match any of the outgoing messages.

context OclMessageExpEval
inv: resultValue = environment.getValueOf( ‘self’ ).outgoingMessages->select( m | m.target = target.resultValue and m.name = self.name and self.arguments->forAll( expArg: OclMessageArgEval | not expArg.resultValue.oclIsUndefined() implies m.arguments->exists( messArg | messArg.value = expArg.value ) )

[192][3] The source of the resulting ocl message value is equal to the ‘self’ object of the ocl message expression.

context OclMessageExpEval
inv: resultValue.source = environment.getValueOf( ‘self’ )

[193][4] The isSent attribute of the resulting ocl message value is true only if the message value is in the outgoing messages of the ‘self’ object.

context OclMessageExpEval
inv:
if resultValue.oclIsUndefined()
resultValue.isSent = false
else
resultValue.isSent = true
endif

[194][5] The target of an ocl message expression is an object value.

context OclMessageExpEval
inv: target.resultValue->isTypeOf( ObjectValue )

[195][6] The environment of all arguments, and the environment of the target expression are equal to the environment of this ocl message value.

context OclMessageExpEval
inv: arguments->forAll( a | a.environment = self.environment )
inv: target.environment = self.environment

10.3.2.24 OclMessageArgEval

[196][1] An ocl message argument evaluation has either an ocl expression evaluation, or an unspecified value expression evaluation, not both.
context OclMessageArgEval inv:
expression->size() = 1 implies unspecified->size() = 0
expression->size() = 0 implies unspecified->size() = 1

[197][2] The result value of an ocl message argument is determined by the result value of its expression, or its unspecified value expression.

context OclMessageArgEval inv:
if expression->size() = 1
then resultValue = expression.resultValue
else resultValue = unspecified.resultValue
endif

[198][3] The environment of the expression and unspecified value are equal to the environment of this ocl message argument.

context OclMessageArgEval
inv: expression.environment = self.environment
inv: unspecified.environment = self.environment

10.3.2.25 OperationCallExpEval

The definition of the semantics of the operation call expression depends on the definition of operation call execution in the UML semantics. This is part of the UML infrastructure specification, and will not be defined here. For the semantics of the OperationCallExp it suffices to know that the execution of an operation call will produce a result of the correct type, as specified in 10.4, The AS-Domain-Mapping Package.

[199][1] The environments of the arguments of an operation call expression are equal to the environment of this call.

context OperationCallExpEval inv:
arguments->forall( a | a.environment = self.environment )

10.3.2.26 PropertyCallExpEval

The result value and environment are determined by its subtypes.

[200][1] The environment of the source of a property call expression is equal to the environment of this call.

context PropertyCallExpEval inv:
source.environment = self.environment

10.3.2.27 PrimitiveLiteralExpEval

No extra well-formedness rules. The result value is determined by its subtypes.

10.3.2.28 RealLiteralExpEval

No extra well-formedness rules. The manner in which the resultValue is determined is given in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.

10.3.2.29 StringLiteralExpEval

No extra well-formedness rules. The manner in which the resultValue is determined is given in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.
10.3.2.30 TupleLiteralExpEval

[201][1] The result value of a tuple literal expression evaluation is a tuple value whose elements correspond to the parts of the tuple literal expression evaluation.

context TupleLiteralExpEval inv:
resultValue.oclIsTypeOf( TupleValue ) and
tuplePart->size() = resultValue.elements->size() and
Sequence{1..tuplePart->size()}->forAll( i: Integer |
resultValue.elements->at(i).name = tuplePart.name and
resultValue.elements->at(i).value = tuplePart.initExpression.resultValue )

10.3.2.31 UnlimitedNaturalLiteralExpEval

No extra well-formedness rules. The manner in which the resultValue is determined is given in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.

10.3.2.32 UnspecifiedValueExpEval

The result of an unspecified value expression is a randomly picked instance of the type of the expression. This rule will be defined in 10.4.3, Well-formedness rules for the AS-Domain-Mapping.exp-eval Package.

10.3.2.33 VariableDeclEval

No extra well-formedness rules.

10.3.2.34 VariableExpEval

[202][1] The result of a VariableExpEval is the value bound to the name of the variable to which it refers.

context VariableExpEval inv:
resultValue = environment.getValueOf(referredVariable.varName)

10.3.3 Additional Operations of the Evaluations Package

10.3.3.1 EvalEnvironment

[203][1] The operation getValueOf results in the value that is bound to the name parameter in the bindings of a name space. Note that the value may be the UndefinedValue.

[204]
context EvalEnvironment::getValueOf(n: String): Value
pre: -- none
post: result = bindings->any(name = n).value

[205][2] The operation replace replaces the value of a name, by the value given in the nvb parameter.

context EvalEnvironment::replace(nvb: NameValueBinding): EvalEnvironment
pre: -- none
post: result.bindings = self.bindings
      ->excluding( self.bindings->any( name = nvb.name ) )->including( nvb )

[206][3] The operation add adds the name and value indicated by the NameValueBinding given by the nvb parameter.

context EvalEnvironment::add(nvb: NameValueBinding): EvalEnvironment
pre: -- none
post: result.bindings = self.bindings->including( nvb )
The operation `addAll` adds all NameValueBindings in the `nvbs` parameter.

```plaintext
class EvalEnvironment::add(nvbs: Collection(NameValueBinding)): EvalEnvironment
  pre: -- none
  post: result.bindings = self.bindings->union(nvbs)
```

### 10.3.3.2 CollectionRangeEval

The operation `getRange()` returns a sequence of integers that contains all integer in the collection range.

```plaintext
class CollectionRangeEval::getRange(first, last: Integer): Sequence(Integer)
  pre: -- none
  post: result = if first = last then
         first->asSequence()
       else
         first->asSequence()->union(getRange(first + 1, last))
     endif
```

### 10.3.4 Overview of the Values Package

Figure 10.13 shows an overview of the inheritance relationships between the classes in the Values package.

![Figure 10.13 - The inheritance tree of classes in the Evaluations package](image-url)
10.4 The AS-Domain-Mapping Package

Figure 10.14 shows the associations between the abstract syntax concepts and the domain concepts defined in this clause. Each domain concept has a counterpart called model in the abstract syntax. Each model has one or more instances in the semantic domain. Note that in particular every OCL expression can have more than one evaluation. Still every evaluation has only one value. For example, the “asSequence” applied to a Set may have n! evaluations, which each give a different permutation of the elements in the set, but each evaluation has exactly one result value.

Figure 10.14 - Associations between values and the types defined in the abstract syntax
10.4.1 Well-formedness rules for the AS-Domain-Mapping.type-value Package

10.4.1.1 CollectionValue

[209][1] All elements in a collection value must have a type that conforms to the elementType of its corresponding CollectionType.

context CollectionValue inv:
  elements->forAll(e: Element | e.value.model.conformsTo( model.elementType ) )

10.4.1.2 DomainElement

No additional well-formedness rules.

10.4.1.3 Element

No additional well-formedness rules.
10.4.1.4 EnumValue
No additional well-formedness rules.

10.4.1.5 ObjectValue
[210][1] All bindings in an object value must correspond to attributes or associations defined in the object’s Classifier.

context ObjectValue inv:
history->forAll( snapshot | snapshot.bindings->forAll( b |
self.model.allAttributes()->exists (attr | b.name = attr.name)
or
self.model.allAssociationEnds()->exists (role | b.name = role.name) ) )

10.4.1.6 OclMessageValue
No additional well-formedness rules.

10.4.1.7 PrimitiveValue
No additional well-formedness rules.

10.4.1.8 SequenceTypeValue
No additional well-formedness rules.

10.4.1.9 SetTypeValue
No additional well-formedness rules.

10.4.1.10 StaticValue
No additional well-formedness rules.

10.4.1.11 TupleValue
[211][1] The elements in a tuple value must have a type that conforms to the type of the corresponding tuple parts.

context TupleValue inv:
elements->forAll( elem |
let correspondingPart: Attribute =
self.model.allAttributes()->select( part | part.name = elem.name ) in
elem.value.model.conformsTo( correspondingPart.type ) )

10.4.1.12 UndefinedValue
No additional well-formedness rules.

10.4.1.13 Value
No additional well-formedness rules.
10.4.2 Additional Operations for the AS-Domain-Mapping.type-value Package

10.4.2.1 Value

[212][1] The additional operation `isInstanceOf` returns true if this value is an instance of the parameter classifier.

context Value::isInstanceOf( c: Classifier ): Boolean
pre: -- none
post: result = self.model.conformsTo( c )

10.4.3 Well-formedness rules for the AS-Domain-Mapping.exp-eval Package

10.4.3.1 AssociationClassCallExpEval

[213][1] The string that represents the referredAssociationClass in the evaluation must be equal to the name of the referredAssociationClass in the corresponding expression.

class context AssociationClassCallExpEval inv:
    referredAssociationClass = model.referredAssociationClass.name

[214][2] The result value of an association class call expression evaluation that has qualifiers, is determined according to the following rule. The ‘normal’ determination of result value is already given in 10.3.2, Well-formedness Rules of the Evaluations Package.

let
-- the attributes that are the formal qualifiers. Because and association class has two or
-- more association ends, we must select the qualifiers from the other end(s), not from
-- the source of this expression. We allow only 2-ary associations.
formalQualifiers : Sequence(Attribute) =
    self.model.referredAssociationClass.connection->any( c | c <> self.navigationSource).qualifier.asSequence() ,

-- the attributes of the class at the qualified end. Here we already assume that an
-- AssociationEnd will be owned by a Classifier, as will most likely be the case in the
-- UML 2.0 Infrastructure.
objectAttributes: Sequence(Attribute) =
    self.model.referredAssociationClass.connection->any( c | c <> self.navigationSource).owner.feature->select( f | f.oclIsTypeOf( Attribute ).asSequence() ,

-- the rolename of the qualified association end
qualifiedEnd: String = self.model.referredAssociationClass.connection->any( c | c <> self.navigationSource).name ,

-- the values for the qualifiers given in the ocl expression
qualifierValues : Sequence( Value ) = self.qualifiers.asSequence()

-- the objects from which a subset must be selected through the qualifiers
normalResult =
    source.resultValue.getCurrentValueOf(referredAssociationClass.name)

in
-- if name of attribute of object at qualified end equals name of formal qualifier then
-- if value of attribute of object at qualified end equals the value given in the exp
-- then select this object and put it in the resultValue of this expression.
qualifiers->size <> 0 implies
10.4.3.2 AssociationEndCallExpEval

[215][1] The string that represents the referredAssociationEnd in the evaluation must be equal to the name of the referredAssociationEnd in the corresponding expression.

context AssociationEndCallExpEval inv:
  referredAssociationEnd = model.referredAssociationEnd.name

[216][2] The result value of an association end call expression evaluation that has qualifiers, is determined according to the following rule. The ‘normal’ determination of result value is already given in 10.3.2, Well-formedness Rules of the Evaluations Package.

let
  -- the attributes that are the formal qualifiers
  formalQualifiers : Sequence(Attribute) = self.model.referredAssociationEnd.qualifier,

  -- the attributes of the class at the qualified end
  objectAttributes: Sequence(Attribute) =
    (if self.resultValue.model.oclIsKindOf( Collection ) implies
    then self.resultValue.model.oclAsType( Collection ).elementType->
    collect( feature->oclAsType( Attribute ) )
    else self.resultValue.model->collect( feature->oclAsType( Attribute ) )
    endif).asSequence() ,

  -- the values for the qualifiers given in the ocl expression
  qualifiersValues : Sequence( Value ) = self.qualifiers.asSequence()

  -- the objects from which a subset must be selected through the qualifiers
  normalResult =
    source.resultValue.getCurrentValueOf(referredAssociationEnd.name)

in
  -- if name of attribute of object at qualified end equals name of formal qualifier then
  -- if value of attribute of object at qualified end equals the value given in the exp
  -- then select this object and put it in the resultValue of this expression.

qualifiers->size <> 0 implies
normalResult->select( obj |
  Sequence(1..formalQualifiers->size())->forAll( i |
    objectAttributes->at(i).name = formalQualifiers->at(i).name and
    obj.qualifiedEnd.getCurrentValueOf( objectAttributes->at(i).name ) =
    qualifiersValues->at(i) ))

10.4.3.3 AttributeCallExpEval

[217][1] The string that represents the referredAttribute in the evaluation must be equal to the name of the referredAttribute in the corresponding expression.

context AttributeCallExpEval inv:
  referredAttribute = model.referredAttribute.name
10.4.3.4 BooleanLiteralExpEval

[218][1] The result value of a boolean literal expression is equal to the literal expression itself (‘true’ or ‘false’). Because the booleanSymbol attribute in the abstract syntax is of type Boolean as defined in the MOF, and resultValue is of type Primitive as defined in this clause, a conversion is necessary. For the moment, we assume the additional operation MOFbooleanToOCLboolean() exists. This will need to be re-examined when the MOF and/or UML Infrastructure submissions are finalized.

context BooleanLiteralExpEval inv:
    resultValue = model.booleanSymbol.MOFbooleanToOCLboolean()

10.4.3.5 CollectionItemEval

No extra well-formedness rules.

10.4.3.6 CollectionLiteralExpEval

No extra well-formedness rules.

10.4.3.7 CollectionLiteralPartEval

No extra well-formedness rules.

10.4.3.8 CollectionRangeEval

No extra well-formedness rules.

10.4.3.9 EvalEnvironment

Because there is no mapping of name space to an abstract syntax concept, there are no extra well-formedness rules.

10.4.3.10 LiteralExpEval

No extra well-formedness rules.

10.4.3.11 LoopExpEval

No extra well-formedness rules.

10.4.3.12 EnumLiteralExpEval

[219][1] The result value of an EnumLiteralExpEval must be equal to one of the literals defined in its type.

context EnumLiteralExpEval inv:
    model.type->includes( self.resultValue )

10.4.3.13 IfExpEval

[220][1] The condition evaluation corresponds with the condition of the expression, and likewise for the thenExpression and the else Expression.

context IfExpEval inv:
    condition.model = model.condition
    thenExpression.model = model.thenExpression
    elseExpression.model = model.elseExpression
10.4.3.14 IntegerLiteralExpEval

context IntegerLiteralExpEval inv:
resultValue = model.integerSymbol

10.4.3.15 IterateExpEval

[221][1] The model of the result of an iterate expression evaluation is equal to the model of the result of the associated IterateExp.

context IterateExpEval
inv: result.model = model.result )

10.4.3.16 IteratorExpEval

No extra well-formedness rules.

10.4.3.17 LetExpEval

[222][1] All parts of a let expression evaluation correspond to the parts of its associated LetExp.

context LetExpEval inv:
in.model = model.in and
initExpression.model = model.initExpression and
variable = model.variable.varName

10.4.3.18 LoopExpEval

[223][1] All sub evaluations have the same model, which is the body of the associated LoopExp.

context LoopExpEval
inv: bodyEvals->forAll( model = self.model )

10.4.3.19 ModelPropertyCallExpEval

No extra well-formedness rules.

10.4.3.20 NumericLiteralExpEval

No extra well-formedness rules.

10.4.3.21 NavigationCallExpEval

[224][1] The string that represents the navigation source in the evaluation must be equal to the name of the navigationSource in the corresponding expression.

context NavigationCallExpEval inv:
navigationSource = model.navigationSource.name

[225][2] The qualifiers of a navigation call expression evaluation must correspond with the qualifiers of the associated expression.

context NavigationCallExpEval inv:
Sequence{1..qualifiers->size()}->forAll( i |
qualifiers->at(i).model = model.qualifiers->at(i).type )
10.4.3.22 OclExpEval

[226][1] The result value of the evaluation of an ocl expression must be an instance of the type of that expression.

context OclExpEval
inv: resultValue.isInstanceOf( model.type )

10.4.3.23 OclMessageExpEval

[227][1] An ocl message expression evaluation must correspond with its message expression.

context OclMessageExpEval
inv: target.model = model.target
inv: Set{1..arguments->size()}-forall (i | arguments->at(i) = model.arguments->at(i) )

[228][2] The name of the resulting ocl message value must be equal to the name of the operation or signal indicated in the message expression.

context OclMessageExpEval inv:
  if model.operation->size() = 1
  then resultValue.name = model.operation.name
  else resultValue.name = model.signal.name
  endif

[229][3] The isSignal, isSyncOperation, and isAsyncOperation attributes of the result value of an ocl message expression evaluation must correspond to the operation indicated in the ocl message expression.

[230]
context OclMessageExpEval inv:
  if model.calledOperation->size() = 1
  then model.calledOperation.isAsynchronous = true implies
    resultValue.isAsyncOperation = true
  else -- message represents sending a signal
    resultValue.isSignal = true
  endif

[231][4] The arguments of an ocl message expression evaluation must correspond to the formal input parameters of the operation, or the attributes of the signal indicated in the ocl message expression.

context OclMessageExpEval
inv:
  model.calledOperation->size() = 1 implies
  Sequence{1.. arguments->size()} -forall ( i | arguments->at(i).variable->size() = 1 implies
    model.calledOperation.operation.parameter->
    select( kind = ParameterDirectionKind::in )->at(i).name =
    arguments->at(i).variable
  and
  arguments->at(i).expression->size() = 1 implies
    model.calledOperation.operation.parameter->
    select( kind = ParameterDirectionKind::in )at(i).type =
    arguments->at(i).expression.model

inv:
  model.sentSignal->size() = 1 implies
  Sequence{1.. arguments->size()} -forall ( i | arguments->at(i).variable->size() = 1 implies
    model.sentSignal.signal.feature->select(
      arguments->at(i).variable )-notEmpty()
  and
  arguments->at(i).expression->size() = 1 implies
The arguments of the return message of an ocl message expression evaluation must correspond to the names given by the formal output parameters, and the result type of the operation indicated in the ocl message expression. Note that the Parameter type is defined in the UML metamodel.

context OclMessageExpEval
inv: let returnArguments: Sequence( NameValueBindings ) = resultValue.returnMessage.arguments ,
    formalParameters: Sequence( Parameter ) = model.calledOperation.operation.parameter
in
    resultValue.returnMessage->size() = 1 and model.calledOperation->size() = 1 implies
    -- 'result' must be present and have correct type
    returnArguments->any( name = 'result' ).value.model = formalParameters->select( kind = ParameterDirectionKind::return ).type
    and
    -- all 'out' parameters must be present and have correct type
    Sequence(1.. returnArguments->size() ) ->forall( i | returnArguments->at(i).name = formalParameters->select( kind = ParameterDirectionKind::out )->at(i).name
    and
    returnArguments->at(i).value.model = formalParameters->select( kind = ParameterDirectionKind::out )->at(i).type )

10.4.3.24 OclMessageArgEval
[233][1] An ocl message argument evaluation must correspond with its argument expression.

context OclMessageArgEval
inv: model.variable->size() = 1 implies variable->size() = 1 and variable.symbol = model.variable.name
inv: model.expression->size() = 1 implies expression and expression.model = model.expression

10.4.3.25 OperationCallExpEval
[234][1] The result value of an operation call expression will have the type given by the Operation being called, if the operation has no out or in/out parameters, else the type will be a tuple containing all out, in/out parameters and the result value.

context OperationCallEval inv:
let outparameters : Set( Parameter ) = referredOperation.parameter->select( p | p.kind = ParameterDirectionKind::in/out or p.kind = ParameterDirectionKind::out)
in
    if outparameters->isEmpty()
        then resultValue.model = model.referredOperation.parameter
        ->select( kind = ParameterDirectionKind::result ).type
    else resultValue.model.oclIsType( TupleType ) and
        outparameters->forall( p |
            resultValue.model.attribute->exist( a | a.name = p.name and a.type = p.type )
        )
endif

[235][2] The string that represents the referred operation in the evaluation must be equal to the name of the referredOperation in the corresponding expression.
context OperationCallExpEval inv:
    referredOperation = model.referredOperation.name

[236][3] The arguments of an operation call expression evaluation must correspond with the arguments of its associated expression.

context OperationCallExpEval inv:
    Sequence(1..arguments->size)->forAll( i |
        arguments->at(i).model = model.arguments->at(i) )

10.4.3.26 PropertyCallExpEval

[237][1] The source of the evaluation of a property call corresponds to the source of its associated expression.

context PropertyCallExpEval inv:
    source.model = model.source

10.4.3.27 PrimitiveLiteralExpEval

No extra well-formedness rules.

10.4.3.28 RealLiteralExpEval

context RealLiteralExpEval inv:
    resultValue = model.realSymbol

10.4.3.29 StringLiteralExpEval

context StringLiteralExpEval inv:
    resultValue = model.stringSymbol

10.4.3.30 TupleLiteralExpEval

context TupleLiteralExpEval inv:
    model.tuplePart = tuplePart.model

10.4.3.31 UnlimitedNaturalLiteralExpEval

context UnlimitedNaturalLiteralExpEval inv:
    resultValue = model.unlimitedNaturalSymbol

10.4.3.32 UnspecifiedValueExpEval

[238][1] The result of an unspecified value expression is a randomly picked instance of the type of the expression.

context UnspecifiedValueExpEval
    inv: resultValue = model.type.allInstances()->any( true )
    inv: resultValue.model = model.type

10.4.3.33 VariableDeclEval

context VariableDeclEval inv:
    model.initExpression = initExpression.model

10.4.3.34 VariableExpEval

No extra well-formedness rules.
11 OCL Standard Library

11.1 Introduction

This clause describes the OCL Standard Library of predefined types, their operations, and predefined expression templates in the OCL. This sub clause contains all standard types defined within OCL, including all the operations defined on those types. For each operation the signature and a description of the semantics is given. Within the description, the reserved word ‘result’ is used to refer to the value that results from evaluating the operation. In several places, post conditions are used to describe properties of the result. When there is more than one postcondition, all postconditions must be true. A similar thing is true for multiple preconditions. If these are used, the operation is only defined if all preconditions evaluate to true.

The structure, syntax, and semantics of the OCL is defined in Clauses 8 (“Abstract Syntax”), 9 (“Concrete Syntax”), and 10 (“Semantics Described using UML”). This clause adds another part to the OCL definition: a library of predefined types and operations. Any implementation of OCL must include this library package. This approach has also been taken by e.g., the Java definition, where the language definition and the standard libraries are both mandatory parts of the complete language definition.

The OCL standard library defines a number of types. It includes several primitive types: UnlimitedNatural, Integer, Real, String, and Boolean. These are familiar from many other languages. The second part of the standard library consists of the collection types. They are Bag, Set, Sequence, and Collection where Collection is an abstract type. Note that all types defined in the OCL standard library are instances of an abstract syntax class. The OCL standard library exists at the modeling level, also referred to as the M1 level, where the abstract syntax is the metalevel or M2 level.

Next to definitions of types the OCL standard library defines a number of template expressions. Many operations defined on collections map not on the abstract syntax metaclass FeatureCallExp, but on the IteratorExp. For each of these a template expression that defines the name and format of the expression is defined in 11.8, ‘Predefined Iterator Expressions.’

The Standard Library may be extended with new types, new operations and new iterators. In particular new operations can be defined for collections.

Certain String operations depend on the prevailing locale to ensure that Strings are collated and characters are case-converted in an appropriate fashion. A locale is defined as a concatenation of up to three character sequences separated by underscores, with the first sequence identifying the language and the second sequence identifying the country. The third sequence is empty but may encode an implementation-specific variant. Trailing empty strings and separators may be omitted.

The character sequences for languages are defined by ISO 639.
The character sequences for countries are defined by ISO 3166.

‘fr_CA’ therefore identifies the locale for the French language in the Canada country.

Comparison of strings and consequently the collation order of Collection::sortedBy() conforms to the Unicode Collation algorithm defined by Unicode Technical Standard#10.

The locale is ‘en_us’ by default but may be configured by a property constraint on OclAny::oclLocale.

The prevailing locale is defined by the prevailing value of oclLocale within the current environment; it may therefore be changed temporarily by using a Let expression.

let oclLocale : String = ‘fr_CA’ in aString.toUpperCase()
11.2 The OclAny, OclVoid, OclInvalid, and OclMessage Types

11.2.1 OclAny

All types in the UML model and the primitive and collection types in the OCL standard library conforms to the type OclAny. Conceptually, OclAny behaves as a supertype for all the types. Features of OclAny are available on each object in all OCL expressions. OclAny is itself an instance of the metatype AnyType.

All classes in a UML model inherit all operations defined on OclAny. To avoid name conflicts between properties in the model and the properties inherited from OclAny, all names on the properties of OclAny start with ‘ocl.’ Although theoretically there may still be name conflicts, they can be avoided. One can also use qualification by OclAny (name of the type) to explicitly refer to the OclAny properties.

Operations of OclAny, where the instance of OclAny is called object.

11.2.2 OclMessage

This sub clause contains the definition of the standard type OclMessage. As defined in this sub clause, each ocl message type is actually a template type with one parameter. ‘T’ denotes the parameter. A concrete ocl message type is created by substituting an operation or signal for the T.

The predefined type OclMessage is an instance of MessageType. Every OclMessage is fully determined by either the operation, or signal given as parameter. Note that there is conceptually an undefined (infinite) number of these types, as each is determined by a different operation or signal. These types are unnamed. Every type has as attributes the name of the operation or signal, and either all formal parameters of the operation, or all attributes of the signal. OclMessage is itself an instance of the metatype MessageType.

OclMessage has a number of predefined operations, as shown in the OCL Standard Library.

11.2.3 OclVoid

The type OclVoid is a type that conforms to all other types except OclInvalid. It has one single instance, identified as null, that corresponds with the UML LiteralNull value specification. Any property call applied on null results in invalid, except for the oclIsUndefined(), oclIsInvalid(), =(OclAny) and ^(OclAny) operations. However, by virtue of the implicit conversion to a collection literal, an expression evaluating to null can be used as source of collection operations (such as ‘isEmpty’). If the source is the null literal, it is implicitly converted to Bag{}.

OclVoid is itself an instance of the metatype VoidType.

11.2.4 OclInvalid

The type OclInvalid is a type that conforms to all other types. It has one single instance, identified as invalid. Any property call applied on invalid results in invalid, except for the operations oclIsUndefined() and oclIsInvalid(). OclInvalid is itself an instance of the metatype InvalidType.

11.3 Operations and Well-formedness Rules

11.3.1 OclAny

=(object2 : OclAny) : Boolean
True if `self` is the same object as `object2`. Infix operator.

    post: result = (self = object2)

`<> (object2 : OclAny) : Boolean`

True if `self` is a different object from `object2`. Infix operator.

    post: result = not (self = object2)

`oclIsNew() : Boolean`

Can only be used in a postcondition. Evaluates to true if the `self` is created during performing the operation (for instance, it didn't exist at precondition time).

    post: self@pre.oclIsUndefined()

`oclIsUndefined() : Boolean`

Evaluates to true if the `self` is equal to `invalid` or equal to null.

    post: result = self.isTypeOf(OclVoid) or self.isTypeOf(OclInvalid)

`oclIsInvalid() : Boolean`

Evaluates to true if the `self` is equal to `OclInvalid`.

    post: result = self.isTypeOf(OclInvalid)

`oclAsType(type : Classifier) : T`

Evaluates to self, where `self` is of the type identified by `T`. The type `T` may be any classifier defined in the UML model; if the actual type of `self` at evaluation time does not conform to `T`, then the `oclAsType` operation evaluates to `invalid`.

In the case of feature redefinition, casting an object to a supertype of its actual type does not access the supertype's definition of the feature; according to the semantics of redefinition, the redefined feature simply does not exist for the object. However, when casting to a supertype, any features additionally defined by the subtype are suppressed.

    post: (result = self) and result.oclIsTypeOf( t )

`oclIsTypeOf(type : Classifier) : Boolean`

Evaluates to true if `self` is of the type `t` but not a subtype of `t`

    post: self.oclType() = type

`oclIsKindOf(type : Classifier) : Boolean`

Evaluates to true if the type of `self` conforms to `t`. That is, `self` is of type `t` or a subtype of `t`.

    post: self.oclType().conformsTo(type)

`oclIsInState(statespec : OclState) : Boolean`

Evaluates to true if the `self` is in the state indentified by `statespec`.

    post: -- TBD

`oclType() : Classifier`

Evaluates to the type of which `self` is an instance.

    post: self.oclIsTypeOf(result)
oclLocale : String
Defines the default locale for local-dependent library operations such as String::toUpperCase().

11.3.2 OclVoid

= (object : OclAny) : Boolean
Redefines the OclAny operation, returning true if object is null.
    post: result = object.oclIsTypeOf(OclVoid)

11.3.3 OclMessage

hasReturned() : Boolean
True if type of template parameter is an operation call, and the called operation has returned a value. This implies the fact that the message has been sent. False in all other cases.
    post: --

result() : <<The return type of the called operation>>
Returns the result of the called operation, if type of template parameter is an operation call, and the called operation has returned a value. Otherwise the invalid value is returned.
    pre: hasReturned()

isSignalSent() : Boolean
Returns true if the OclMessage represents the sending of a UML Signal.

isOperationCall() : Boolean
Returns true if the OclMessage represents the sending of a UML Operation call.

11.4 Primitive Types

The primitive types defined in the OCL standard library are UnlimitedNatural, Integer, Real, String, and Boolean. They are all instances of the metaclass Primitive from the UML core package.

11.4.1 Real
The standard type Real represents the mathematical concept of real. Note that UnlimitedNatural is a subclass of Integer and that Integer is a subclass of Real, so for each parameter of type Real, you can use an unlimited natural or an integer as the actual parameter. Real is itself an instance of the metatype PrimitiveType (from UML).

11.4.2 Integer
The standard type Integer represents the mathematical concept of integer. Note that UnlimitedNatural is a subclass of Integer, so for each parameter of type Integer, you can use an unlimited natural as the actual parameter. Integer is itself an instance of the metatype PrimitiveType (from UML).
11.4.3 String

The standard type String represents string. A string is a sequence of characters in some suitable character set used to display information about the model. Character sets may include non-Roman alphabets and characters. String is itself an instance of the metatype PrimitiveType (from UML).

11.4.4 Boolean

The standard type Boolean represents the common true/false values. Boolean is itself an instance of the metatype PrimitiveType (from UML).

11.4.5 UnlimitedNatural

The standard type UnlimitedNatural is used to encode the non-negative values of a multiplicity specification. This includes a special unlimited value (*) that encodes the upper value of a multiplicity specification. UnlimitedNatural is itself an instance of the metatype UnlimitedNaturalType.

Note that although UnlimitedNatural is a subclass of Integer, the unlimited value cannot be represented as an Integer. Any use of the unlimited value as an integer or real is replaced by the invalid value.

11.5 Operations and Well-formedness Rules

This sub clause contains the operations and well-formedness rules of the primitive types.

11.5.1 Real

Note that UnlimitedNatural is a subclass of Integer and that Integer is a subclass of Real, so for each parameter of type Real, you can use an unlimited natural or an integer as the actual parameter.

+ (r : Real) : Real
The value of the addition of self and r.

- (r : Real) : Real
The value of the subtraction of r from self.

* (r : Real) : Real
The value of the multiplication of self and r.

- : Real
The negative value of self.

/ (r : Real) : Real
The value of self divided by r. Evaluates to invalid if r is equal to zero.

abs() : Real
The absolute value of self.
ISO/IEC 19507:2012(E)

post: if self < 0 then result = - self else result = self endif

floor() : Integer
The largest integer that is less than or equal to self.
post: (result <= self) and (result + 1 > self)

round() : Integer
The integer that is closest to self. When there are two such integers, the largest one.
post: ((self - result).abs() < 0.5) or ((self - result).abs() = 0.5 and (result > self))

max(r : Real) : Real
The maximum of self and r.
post: if self >= r then result = self else result = r endif

min(r : Real) : Real
The minimum of self and r.
post: if self <= r then result = self else result = r endif

< (r : Real) : Boolean
True if self is less than r.

> (r : Real) : Boolean
True if self is greater than r.
post: result = not (self <= r)

<= (r : Real) : Boolean
True if self is less than or equal to r.
post: result = ((self = r) or (self < r))

>= (r : Real) : Boolean
True if self is greater than or equal to r.
post: result = ((self = r) or (self > r))

toString() : String
Converts self to a string value.

11.5.2 Integer
Note that UnlimitedNatural is a subclass of Integer, so for each parameter of type Integer, you can use an unlimited natural as the actual parameter.

- : Integer
The negative value of self.
+ (i : Integer) : Integer
The value of the addition of self and i.

- (i : Integer) : Integer
The value of the subtraction of i from self.

* (i : Integer) : Integer
The value of the multiplication of self and i.

/ (i : Integer) : Real
The value of self divided by i. Evaluates to invalid if r is equal to zero.

abs() : Integer
The absolute value of self.

post: if self < 0 then result = - self else result = self endif

div( i : Integer) : Integer
The number of times that i fits completely within self.

pre : i <> 0
post: if self / i >= 0 then result = (self / i).floor()
else result = -((-self/i).floor())
endf

mod( i : Integer) : Integer
The result is self modulo i.

post: result = self - (self.div(i) * i)

max(i : Integer) : Integer
The maximum of self an i.

post: if self >= i then result = self else result = i endif

min(i : Integer) : Integer
The minimum of self an i.

post: if self <= i then result = self else result = i endif

toString() : String
Converts self to a string value.

11.5.3 String

+ (s : String) : String
The concatenation of self and s.

post: result = self.concat(s)
size() : Integer
The number of characters in self.

concat(s : String) : String
The concatenation of self and s.

    post: result.size() = self.size() + string.size()
    post: result.substring(1, self.size() ) = self
    post: result.substring(self.size() + 1, result.size() ) = s

substring(lower : Integer, upper : Integer) : String
The sub-string of self starting at character number lower, up to and including character number upper. Character numbers run from 1 to self.size().

    pre: 1 <= lower
    pre: lower <= upper
    pre: upper <= self.size()

toInteger() : Integer
Converts self to an Integer value.

toReal() : Real
Converts self to a Real value.

toUpperCase() : String
Converts self to upper case, using the locale defined by looking up oclLocale in the current environment. Otherwise, returns the same string as self.

toLowerCase() : String
Converts self to lower case, using the locale defined by looking up oclLocale in the current environment. Otherwise, returns the same string as self.

indexOf(s : String) : Integer
Queries the index in self at which s is a substring of self, or zero if s is not a substring of self. The empty string is considered to be a substring of every string but the empty string, at index 1. No string is a substring of the empty string.

    post: self.size() = 0 implies result = 0
    post: s.size() = 0 and self.size() > 0 implies result = 1
    post: s.size() > 0 and result > 0 implies self.substring(result, result + s.size() - 1) = s

equalsIgnoreCase(s : String) : Boolean
Queries whether s and self are equivalent under case-insensitive collation.

    post: result = (self.toUpperCase() = s.toUpperCase())

at(i : Integer) : String
Queries the character at position i in self.
pre: i > 0
pre: i <= self.size()
post: result = self.substring(i, i)

def characters() : Sequence(String)
Obtains the characters of self as a sequence.
    post: result =
        if self.size() = 0 then
            Sequence{}
        else
            Sequence{1..self.size()]->iterate(i; acc : Sequence(String) = Sequence{} | 
            acc->append(self.at(i)))
        endif

toBoolean() : Boolean
Converts self to a boolean value.
    post: result = (self = 'true')

< (s : String) : Boolean
True if self is less than s, using the locale defined by looking up oclLocale in the current environment.

> (s : String) : Boolean
True if self is greater than s, using the locale defined by looking up oclLocale in the current environment.
    post: result = not (self <= s)

<= (s : String) : Boolean
True if self is less than or equal to s, using the locale defined by looking up oclLocale in the current environment.
    post: result = ((self = s) or (self < s))

>= (s : String) : Boolean
True if self is greater than or equal to s, using the locale defined by looking up oclLocale in the current environment.
    post: result = ((self = s) or (self > s))

11.5.4 Boolean

or (b : Boolean) : Boolean
True if either self or b is true.

xor (b : Boolean) : Boolean
True if either self or b is true, but not both.
    post: (self or b) and not (self = b)

and (b : Boolean) : Boolean
True if both \( b1 \) and \( b \) are true.

\textbf{not : Boolean}

True if \( self \) is false.

\hspace{1cm} \textbf{post:} \text{if \( self \) then result = false else result = true endif}

\textbf{implies (b : Boolean) : Boolean}

True if \( self \) is false, or if \( self \) is true and \( b \) is true.

\hspace{1cm} \textbf{post:} \( \text{not self} \) or \( \text{(self and b)} \)

\textbf{toString() : String}

Converts \( self \) to a string value.

\textbf{11.5.5 UnlimitedNatural}

\textbf{+ (u : UnlimitedNatural) : UnlimitedNatural}

The value of the addition of \( self \) and \( u \). Evaluates to invalid if \( self \) or \( u \) is unlimited.

\textbf{* (u : UnlimitedNatural) : UnlimitedNatural}

The value of the multiplication of \( self \) and \( u \). Evaluates to invalid if \( self \) or \( u \) is unlimited.

\textbf{/ (u : UnlimitedNatural) : Real}

The value of \( self \) divided by \( u \). Evaluates to invalid if \( u \) is equal to zero or unlimited, or if \( self \) is unlimited.

\textbf{div(u : UnlimitedNatural) : UnlimitedNatural}

The number of times that \( u \) fits completely within \( self \). Evaluates to invalid if \( u \) is equal to zero or unlimited, or if \( self \) is unlimited.

\hspace{1cm} \textbf{post:} \( \text{result} = (self / u).floor() \)

\textbf{mod(u : UnlimitedNatural) : UnlimitedNatural}

The result is \( self \) modulo \( u \). Evaluates to invalid if \( u \) is equal to zero or unlimited, or if \( self \) is unlimited.

\hspace{1cm} \textbf{post:} \( \text{result} = \text{self} - (\text{self.div(u)} * \text{u}) \)

\textbf{max(u : UnlimitedNatural) : UnlimitedNatural}

The maximum of \( self \) and \( u \).

\hspace{1cm} \textbf{post:} \text{if \( self = * \) or \( u = * \) then result = * else if \( self \geq u \) then result = \( self \) else result = \( u \) endif endif}

\textbf{min(u : UnlimitedNatural) : UnlimitedNatural}

The minimum of \( self \) and \( u \).

\hspace{1cm} \textbf{post:} \text{if \( self = * \) then result = \( u \) else if \( u = * \) then result = \( self \) else if \( self \leq u \) then result = \( self \) else result = \( u \) endif endif endif}
< (u : UnlimitedNatural) : Boolean
True if \( self \) is less than \( u \).
  
  \[
  \text{post: if } self = \ast \text{ then result = false} \\
  \text{else if } u = \ast \text{ then result = true} \\
  \text{else result = self.toInteger()} < u.toInteger() \]

> (u : UnlimitedNatural) : Boolean
True if \( self \) is greater than \( u \).
  
  \[
  \text{post: if } u = \ast \text{ then result = false} \\
  \text{else if } self = \ast \text{ then result = true} \\
  \text{else result = self.toInteger()} > u.toInteger() \]

<= (u : UnlimitedNatural) : Boolean
True if \( self \) is less than or equal to \( u \).
  
  \[
  \text{post: if } u = \ast \text{ then result = true} \\
  \text{else if } self = \ast \text{ then result = false} \\
  \text{else result = self.toInteger()} <= u.toInteger() \]

>= (u : UnlimitedNatural) : Boolean
True if \( self \) is greater than or equal to \( u \).
  
  \[
  \text{post: if } self = \ast \text{ then result = true} \\
  \text{else if } u = \ast \text{ then result = false} \\
  \text{else result = self.toInteger()} >= u.toInteger() \]

toInteger() : Integer
Converts \( self \) to an integer value. If \( self \) is \textit{unlimited} the result is \textit{invalid}.
  
  \[
  \text{post: if } self = \ast \text{ then result = invalid} \\
  \text{else result = self.oclAsType(Integer) \} \}

toString() : String
Converts \( self \) to a string value, using the canonical form as defined by http://www.w3.org/TR/xmlschema-2/
#nonNegativeInteger. If \( self \) is \textit{unlimited} the result is '\(*\}'.

11.6 Collection-Related Types
This sub clause defines the collection types and their operations. As defined in this sub clause, each collection type is
actually a template type with one parameter. ‘T’ denotes the parameter. A concrete collection type is created by
substituting a type for the T. So Set (Integer) and Bag (Person) are collection types.
11.6.1 Collection

Collection is the abstract supertype of all collection types in the OCL Standard Library. Each occurrence of an object in a collection is called an *element*. If an object occurs twice in a collection, there are two elements. This sub clause defines the properties on Collections that have identical semantics for all collection subtypes. Some operations may be defined within the subtype as well, which means that there is an additional postcondition or a more specialized return value. Collection is itself an instance of the metatype CollectionType.

The definition of several common operations is different for each subtype. These operations are not mentioned in this sub clause.

The semantics of the collection operations is given in the form of a postcondition that uses the *IterateExp* of the *IteratorExp* construct. The semantics of those constructs is defined in Clause 10 (“Semantics Described using UML”). In several cases the postcondition refers to other collection operations, which in turn are defined in terms of the *IterateExp* or *IteratorExp* constructs.

11.6.2 Set

The Set is the mathematical set. It contains elements without duplicates. Set is itself an instance of the metatype SetType.

11.6.3 OrderedSet

The OrderedSet is a Set, the elements of which are ordered. It contains no duplicates. OrderedSet is itself an instance of the metatype OrderedSetType.

An OrderedSet is not a subtype of Set, neither a subtype of Sequence. The common supertype of Sets and OrderedSets is Collection.

11.6.4 Bag

A bag is a collection with duplicates allowed. That is, one object can be an element of a bag many times. There is no ordering defined on the elements in a bag. Bag is itself an instance of the metatype BagType.

11.6.5 Sequence

A sequence is a collection where the elements are ordered. An element may be part of a sequence more than once. Sequence is itself an instance of the metatype SequenceType.

A Sentence is not a subtype of Bag. The common supertype of Sentence and Bags is Collection.

11.7 Operations and Well-formedness Rules

This sub clause contains the operations and well-formedness rules of the collection types.

11.7.1 Collection

\[= (c : \text{Collection}(T)) : \text{Boolean}\]

True if \(c\) is a collection of the same kind as self and contains the same elements in the same quantities and in the same order, in the case of an ordered collection type.
<> (c : Collection(T)) : Boolean
True if c is not equal to self.
   post: result = not (self = c)

size() : Integer
The number of elements in the collection self.
   post: result = self->iterate(elem; acc : Integer = 0 | acc + 1)

includes(object : T) : Boolean
True if object is an element of self, false otherwise.
   post: result = (self->count(object) > 0)

excludes(object : T) : Boolean
True if object is not an element of self, false otherwise.
   post: result = (self->count(object) = 0)

count(object : T) : Integer
The number of times that object occurs in the collection self.
   post: result = self->iterate( elem; acc : Integer = 0 | if elem = object then acc + 1 else acc endif)

includesAll(c2 : Collection(T)) : Boolean
Does self contain all the elements of c2 ?
   post: result = c2->forAll(elem | self->includes(elem))

excludesAll(c2 : Collection(T)) : Boolean
Does self contain none of the elements of c2 ?
   post: result = c2->forAll(elem | self->excludes(elem))

isEmpty() : Boolean
Is self the empty collection?
   post: result = ( self->size() = 0 )

Note: null->isEmpty() returns 'true' in virtue of the implicit casting from null to Bag{}

notEmpty() : Boolean
Is self not the empty collection?
   post: result = ( self->size() <> 0 )
null->notEmpty() returns 'false' in virtue of the implicit casting from null to Bag{}

max() : T
The element with the maximum value of all elements in self. Elements must be of a type supporting the max operation. The max operation - supported by the elements - must take one parameter of type T and be both associative and commutative. UnlimitedNatural, Integer and Real fulfill this condition.

\[
\text{post: result} = \text{self->iterate( elem; acc : T = self.first() | acc.max(elem) )}
\]

\[
\text{min()} : T
\]

The element with the minimum value of all elements in self. Elements must be of a type supporting the min operation. The min operation - supported by the elements - must take one parameter of type T and be both associative and commutative. UnlimitedNatural, Integer and Real fulfill this condition.

\[
\text{post: result} = \text{self->iterate( elem; acc : T = self.first() | acc.min(elem) )}
\]

\[
\text{sum()} : T
\]

The addition of all elements in self. Elements must be of a type supporting the + operation. The + operation must take one parameter of type T and be both associative: \((a+b)+c = a+(b+c)\), and commutative: \(a+b = b+a\). UnlimitedNatural, Integer and Real fulfill this condition.

\[
\text{post: result} = \text{self->iterate( elem; acc : T = 0 | acc + elem )}
\]

If the + operation is not both associative and commutative, the sum expression is not well-formed, which may result in unpredictable results during evaluation. If an implementation is able to detect a lack of associativity or commutativity, the implementation may bypass the evaluation and return an invalid result.

\[
\text{product(c2: Collection(T2)) : Set( Tuple( first: T, second: T2) )}
\]

The cartesian product operation of self and c2.

\[
\text{post: result} = \text{self->iterate( e1; acc: Set(Tuple(first: T, second: T2)) = Set{} | c2->iterate (e2; acc2: Set(Tuple(first: T, second: T2)) = acc | acc2->including (Tuple{first = e1, second = e2}) ))}
\]

\[
\text{asSet()} : \text{Set(T)}
\]

The Set containing all the elements from self, with duplicates removed.

\[
\text{post: result->forAll(elem | self ->includes(elem))}
\]

\[
\text{asOrderedSet()} : \text{OrderedSet(T)}
\]

An OrderedSet that contains all the elements from self, with duplicates removed, in an order dependent on the particular concrete collection type.

\[
\text{post: result->forAll(elem | self->includes(elem))}
\]

\[
\text{asSequence()} : \text{Sequence(T)}
\]

A Sequence that contains all the elements from self, in an order dependent on the particular concrete collection type.

\[
\text{post: result->forAll(elem | self->includes(elem))}
\]

\[
\text{asBag()} : \text{Bag(T)}
\]

The Bag that contains all the elements from self.
flatten() : Collection(T2)

If the element type is not a collection type, this results in the same collection as self. If the element type is a collection type, the result is a collection containing all the elements of all the recursively flattened elements of self.

[1] Well-formedness rules

context Collection
   inv: self->forAll(not oclIsInvalid())

11.7.2 Set

union(s : Set(T)) : Set(T)

The union of self and s.
   post: result->forAll(elem | self->includes(elem) or s->includes(elem))
   post: self ->forAll(elem | result->includes(elem))
   post: s ->forAll(elem | result->includes(elem))

union(bag : Bag(T)) : Bag(T)

The union of self and bag.
   post: result->forAll(elem | result->count(elem) = self->count(elem) + bag->count(elem))
   post: self->forAll(elem | result->includes(elem))
   post: bag ->forAll(elem | result->includes(elem))

= (s : Set(T)) : Boolean

Evaluates to true if self and s contain the same elements.
   post: result = (self->forAll(elem | s->includes(elem)) and 
         s->forAll(elem | self->includes(elem)) )

intersection(s : Set(T)) : Set(T)

The intersection of self and s (i.e., the set of all elements that are in both self and s).
   post: result->forAll(elem | self->includes(elem) and s->includes(elem))
   post: self->forAll(elem | s ->includes(elem) = result->includes(elem))
   post: s ->forAll(elem | self->includes(elem) = result->includes(elem))

intersection(bag : Bag(T)) : Set(T)

The intersection of self and bag.
   post: result = self->intersection( bag->asSet )

~ (s : Set(T)) : Set(T)

The elements of self, which are not in s.
   post: result->forAll(elem | self->includes(elem) and s->excludes(elem))
post: self - >forall(elem | result->includes(elem) = s->excludes(elem))

including(object : T) : Set(T)
The set containing all elements of self plus object.
post: result->forall(elem | self->includes(elem) or (elem = object))
post: self->forall(elem | result->includes(elem))
post: result->includes(object)

excluding(object : T) : Set(T)
The set containing all elements of self without object.
post: result->forall(elem | self->includes(elem) and (elem <> object))
post: self->forall(elem | result->includes(elem) = (object <> elem))
post: result->excludes(object)

symmetricDifference(s : Set(T)) : Set(T)
The sets containing all the elements that are in self or s, but not in both.
post: result->forall(elem | self->includes(elem) xor s->includes(elem))
post: self->forall(elem | result->includes(elem) = s->excludes(elem))
post: s->forall(elem | result->includes(elem) = self->excludes(elem))

count(object : T) : Integer
The number of occurrences of object in self.
post: result <= 1

flatten() : Set(T2)
Redefines the Collection operation. If the element type is not a collection type, this results in the same set as self. If the element type is a collection type, the result is the set containing all the elements of all the recursively flattened elements of self.

post: result = if self.oclType().elementType.oclIsKindOf(CollectionType) then
    self->iterate(c; acc : Set(T2) = Set{} | acc->union(c->flatten()->asSet() ) )
else
    self
endif

asSet() : Set(T)
Redefines the Collection operation. A Set identical to self. This operation exists for convenience reasons.
post: result = self

asOrderedSet() : OrderedSet(T)
Redefines the Collection operation. An OrderedSet that contains all the elements from self, in undefined order.
post: result->forall(elem | self->includes(elem))
asSequence() : Sequence(T)
Redefines the Collection operation. A Sequence that contains all the elements from self, in undefined order.
  post: result->forAll(elem | self->includes(elem))
  post: self->forAll(elem | result->count(elem) = 1)

asBag() : Bag(T)
Redefines the Collection operation. The Bag that contains all the elements from self.
  post: result->forAll(elem | self->includes(elem))
  post: self->forAll(elem | result->count(elem) = 1)

11.7.3 OrderedSet

append (object: T) : OrderedSet(T)
The set of elements, consisting of all elements of self, followed by object.
  post: result->size() = self->size() + 1
  post: result->at(result->size() ) = object
  post: Sequence{1..self->size()}->forAll(index : Integer | result->at(index) = self->at(index))

prepend(object : T) : OrderedSet(T)
The sequence consisting of object, followed by all elements in self.
  post: result->size = self->size() + 1
  post: result->at(1) = object
  post: Sequence{1..self->size()}->forAll(index : Integer | result->at(index) = self->at(index + 1))

insertAt(index : Integer, object : T) : OrderedSet(T)
The set consisting of self with object inserted at position index.
  post: result->size = self->size() + 1
  post: result->at(index) = object
  post: Sequence{1..(index - 1)}->forAll(i : Integer | self->at(i) = result->at(i))
  post: Sequence{((index + 1)..self->size())}->forAll(i : Integer | self->at(i) = result->at(i + 1))

subOrderedSet(lower : Integer, upper : Integer) : OrderedSet(T)
The sub-set of self starting at number lower, up to and including element number upper.
  pre : 1 <= lower
  pre : lower <= upper
  pre : upper <= self->size()
  post: result->size() = upper -lower + 1
post: Sequence{lower..upper}->forAll( index |
result->at(index - lower + 1) =
self->at(index))

at(i : Integer) : T
The i-th element of self.
pre : i >= 1 and i <= self->size()

indexOf(obj : T) : Integer
The index of object obj in the sequence.
pre : self->includes(obj)
post : self->at(i) = obj

first() : T
The first element in self.
post: result = self->at(1)

last() : T
The last element in self.
post: result = self->at(self->size() )

reverse() : OrderedSet(T)
The ordered set of elements with same elements but with the opposite order.
post: result->size() = self->size()

sum() : T
Redefines the Collection operation to remove the requirement for the + operation to be associative and/or commutative, since the order of evaluation is well-defined by the iteration over an ordered collection.

asSet() : Set(T)
Redefines the Set operation. Returns a Set containing all of the elements of self, in undefined order.

asOrderedSet() : OrderedSet(T)
Redefines the Set operation. An OrderedSet identical to self.
post: result = self
post: Sequence{1..self.size()}->forAll(i | result->at(i) = self->at(i))

asSequence() : Sequence(T)
Redefines the Set operation. A Sequence that contains all the elements from self, in the same order.
post: Sequence{1..self.size()}->forAll(i | result->at(i) = self->at(i))

asBag() : Bag(T)
Redefines the Set operation. The Bag that contains all the elements from self, in undefined order.
11.7.4 Bag

= (bag : Bag(T)) : Boolean

True if self and bag contain the same elements, the same number of times.
post: result = (self->forAll(elem | self->count(elem) = bag->count(elem)) and
bag->forAll(elem | bag->count(elem) = self->count(elem)) )

union(bag : Bag(T)) : Bag(T)

The union of self and bag.
post: result->forAll( elem | result->count(elem) = self->count(elem) + bag->count(elem))
post: self ->forAll( elem | result->count(elem) = self->count(elem) + bag->count(elem))
post: bag ->forAll( elem | result->count(elem) = self->count(elem) + bag->count(elem))

union(set : Set(T)) : Bag(T)

The union of self and set.
post: result->forAll( elem | result->count(elem) = self->count(elem) + set->count(elem))
post: self ->forAll( elem | result->count(elem) = self->count(elem) + set->count(elem))
post: set ->forAll( elem | result->count(elem) = self->count(elem) + set->count(elem))

intersection(bag : Bag(T)) : Bag(T)

The intersection of self and bag.
post: result->forAll( elem | result->count(elem) = self->count(elem).min(bag->count(elem)) )
post: self ->forAll( elem | result->count(elem) = self->count(elem).min(bag->count(elem)) )
post: bag ->forAll( elem | result->count(elem) = self->count(elem).min(bag->count(elem)) )

intersection(set : Set(T)) : Set(T)

The intersection of self and set.
post: result->forAll( elem | result->count(elem) = self->count(elem).min(set->count(elem)) )
post: self ->forAll( elem | result->count(elem) = self->count(elem).min(set->count(elem)) )
post: set ->forAll( elem | result->count(elem) = self->count(elem).min(set->count(elem)) )

including(object : T) : Bag(T)

The bag containing all elements of self plus object.
post: result->forAll( elem |
if elem = object then
  result->count(elem) = self->count(elem) + 1
else
  result->count(elem) = self->count(elem)
endif)
post: self->forAll( elem |
if elem = object then
    result->count(elem) = self->count(elem) + 1
else
    result->count(elem) = self->count(elem)
endif)

excluding(object : T) : Bag(T)
The bag containing all elements of self apart from all occurrences of object.

post: result->forAll(elem |
    if elem = object then
    result->count(elem) = 0
    else
    result->count(elem) = self->count(elem)
    endif)

post: self->forAll(elem |
    if elem = object then
    result->count(elem) = 0
    else
    result->count(elem) = self->count(elem)
    endif)

count(object : T) : Integer
The number of occurrences of object in self.

flatten() : Bag(T2)
Redefines the Collection operation. If the element type is not a collection type, this results in the same bag as self. If the element type is a collection type, the result is the bag containing all the elements of all the recursively flattened elements of self.

post: result = if self.oclType().elementType.oclIsKindOf(CollectionType) then
    self->iterate(c; acc : Bag(T2) = Bag{} |
        acc->union(c->flatten()->asBag() ) )
else
    self
endif

asBag() : Bag(T)
Redefines the Collection operation. A Bag identical to self. This operation exists for convenience reasons.

post: result = self

asSequence() : Sequence(T)
Redefines the Collection operation. A Sequence that contains all the elements from self, in undefined order.

post: result->forAll(elem | self->count(elem) = result->count(elem))
post: self ->forAll(elem | self->count(elem) = result->count(elem))
asSet() : Set(T)
Redefines the Collection operation. The Set containing all the elements from self, with duplicates removed.
post: result->forAll(elem | self ->includes(elem))
post: self ->forAll(elem | result->includes(elem))

asOrderedSet() : OrderedSet(T)
Redefines the Collection operation. An OrderedSet that contains all the elements from self, in undefined order, with duplicates removed.
post: result->forAll(elem | self ->includes(elem))
post: self ->forAll(elem | result->includes(elem))
post: self ->forAll(elem | result->count(elem) = 1)

11.7.5 Sequence

count(object : T) : Integer
The number of occurrences of object in self.

= (s : Sequence(T)) : Boolean
True if self contains the same elements as s in the same order.
post: result = Sequence{1..self->size()}->forAll(index : Integer |
self->at(index) = s->at(index))
and
self->size() = s->size()

union (s : Sequence(T)) : Sequence(T)
The sequence consisting of all elements in self, followed by all elements in s.
post: result->size() = self->size() + s->size()
post: Sequence{1..self->size()}->forAll(index : Integer |
self->at(index) = result->at(index))
post: Sequence{1..s->size()}->forAll(index : Integer |
s->at(index) = result->at(index + self->size()) )

flatten() : Sequence(T2)
Redefines the Collection operation. If the element type is not a collection type, this results in the same sequence as self. If the element type is a collection type, the result is the sequence containing all the elements of all the recursively flattened elements of self. The order of the elements is partial.
post: result = if self.oclType().elementType.oclIsKindOf(CollectionType) then
  self->iterate(c; acc : Sequence(T2) = Sequence{} |
  acc->union(c->flatten()->asSequence() ) )
else
  self
endif
**ISO/IEC 19507:2012(E)**

**append (object: T) : Sequence(T)**

The sequence of elements, consisting of all elements of *self*, followed by *object*.

- post: result->size() = self->size() + 1
- post: result->at(result->size()) = object
- post: Sequence{1..self->size()}->forall(index : Integer |
  result->at(index) = self->at(index))

**prepend(object : T) : Sequence(T)**

The sequence consisting of *object*, followed by all elements in *self*.

- post: result->size = self->size() + 1
- post: result->at(1) = object
- post: Sequence{1..self->size()]->forall(index : Integer |
  self->at(index) = result->at(index + 1))

**insertAt(index : Integer, object : T) : Sequence(T)**

The sequence consisting of *self* with *object* inserted at position *index*.

- post: result->size = self->size() + 1
- post: result->at(index) = object
- post: Sequence{1..(index - 1)}->forall(i : Integer |
  self->at(i) = result->at(i))
- post: Sequence{((index + 1)..self->size()-forAll(i : Integer |
  self->at(i) = result->at(i + 1))}

**subSequence(lower : Integer, upper : Integer) : Sequence(T)**

The sub-sequence of *self* starting at number *lower*, up to and including element number *upper*.

- pre : 1 <= lower
- pre : lower <= upper
- pre : upper <= self->size()
- post: result->size() = upper - lower + 1
- post: Sequence{lower..upper}->forall(index |
  result->at(index - lower + 1) =
  self->at(index))

**at(i : Integer) : T**

The *i*-th element of sequence.

- pre : i >= 1 and i <= self->size()

**indexOf(obj : T) : Integer**

The index of object *obj* in the sequence.

- pre : self->includes(obj)
- post: self->at(i) = obj
first() : T

The first element in self.

post: result = self->at(1)

last() : T

The last element in self.

post: result = self->at(self->size() )

including(object : T) : Sequence(T)

The sequence containing all elements of self plus object added as the last element.

post: result = self.append(object)

excluding(object : T) : Sequence(T)

The sequence containing all elements of self apart from all occurrences of object. The order of the remaining elements is not changed.

post: result->includes(object) = false
post: result->size() = self->size() - self->count(object)
post: result = self->iterate(elem; acc : Sequence(T)
    = Sequence{}
    if elem = object then acc else acc->append(elem) endif )

reverse() : Sequence(T)

The sequence containing the same elements but with the opposite order.

post: result->size() = self->size()

sum() : T

Redefines the Collection operation to remove the requirement for the + operation to be associative and/or commutative, since the order of evaluation is well-defined by the iteration over an ordered collection.

asBag() : Bag(T)

Redefines the Collection operation. The Bag containing all the elements from self, including duplicates.

post: result->forAll(elem | self->count(elem) = result->count(elem))
post: self->forAll(elem | self->count(elem) = result->count(elem))

asSequence() : Sequence(T)

Redefines the Collection operation. The Sequence identical to the object itself. This operation exists for convenience reasons.

post: result = self

asSet() : Set(T)

Redefines the Collection operation. The Set containing all the elements from self, with duplicates removed.

post: result->forAll(elem | self ->includes(elem))
post: self ->forAll(elem | result->includes(elem))
asOrderedSet() : OrderedSet(T)

Redefines the Collection operation. An OrderedSet that contains all the elements from self, in the same order, with duplicates removed.

\[
\begin{align*}
\text{post: } & \text{result->forAll(elem | self ->includes(elem))} \\
\text{post: } & \text{self ->forAll(elem | result->includes(elem))} \\
\text{post: } & \text{self ->forAll(elem | result->count(elem) = 1)} \\
\text{post: } & \text{self ->forAll(elem1, elem2 | self->indexOf(elem1) < self->indexOf(elem2) \implies result->indexOf(elem1) < result->indexOf(elem2))}
\end{align*}
\]

11.8 Predefined Iterator Expressions

This sub clause defines the standard OCL iterator expressions. In the abstract syntax these are all instances of IteratorExp. These iterator expressions always have a collection expression as their source, as is defined in the well-formedness rules in Clause 8 (“Abstract Syntax”). The defined iterator expressions are shown per source collection type. The semantics of each iterator expression is defined through a mapping from the iterator to the ‘iterate’ construct. This means that the semantics of the iterator expressions do not need to be defined separately in the semantics sub clauses.

In all of the following OCL expressions, the lefthand side of the equals sign is the IteratorExp to be defined, and the righthand side of the equals sign is the equivalent as an IterateExp. The names source, body, and iterator refer to the role names in the abstract syntax:

<table>
<thead>
<tr>
<th>source</th>
<th>The source expression of the IteratorExp.</th>
</tr>
</thead>
<tbody>
<tr>
<td>body</td>
<td>The body expression of the IteratorExp.</td>
</tr>
<tr>
<td>iterator</td>
<td>The iterator variable of the IteratorExp.</td>
</tr>
<tr>
<td>result</td>
<td>The result variable of the IterateExp.</td>
</tr>
</tbody>
</table>

11.8.1 Extending the Standard Library with Iterator Expressions

It is possible to add new iterator expressions in the standard library. If this is done the semantics of a new iterator should be defined by mapping it to existing constructs, in the same way the semantics of pre-defined iterators is done (see sub clause 11.9)

11.9 Mapping Rules for Predefined Iterator Expressions

This sub clause contains the operations and well-formedness rules of the collection types.

11.9.1 Collection

closure

The closure of applying body transitively to every distinct element of the source collection.

\[
\begin{align*}
\text{source->closure(iterator | body) =} \\
\text{anonRecurse(source, Result{}})
\end{align*}
\]

where:
anonRecurse is an invocation-site-specific helper function synthesized by lexical substitution of iterator, body, add and Result in:

context OclAny
def: anonRecurse(anonSources : Collection(T), anonInit : Result(T)) : Result(T) =
anonSources->iterate(iterator : T; anonAcc : Result(T) = anonInit |
  if anonAcc->includes(iterator)
    then anonAcc
  else let anonBody : OclAny = body in
    let anonResults : Result(T) = anonAcc->add(iterator) in
    if anonBody.oclIsKindOf(CollectionType)
      then anonRecurse(anonBody.oclAsType(Collection(T)), anonResults)
    else anonRecurse(anonBody.oclAsType(T)->asSet(), anonResults)
    endif
  endif
endif

where:

  T is the element type of the source collection.
  Result is 'OrderedSet' if the source collection is ordered, 'Set' otherwise.
  add is 'append' if the source collection is ordered, 'including' otherwise.

The anonymous variables 'anonRecurse', 'anonAcc', 'anonInit', 'anonResults' and 'anonSources' are named for exposition purposes; they do not form part of the evaluation environment for body.

11.9.1.1 exists

Results in true if body evaluates to true for at least one element in the source collection.

  source->exists(iterators | body) =
  source->iterate(iterators; result : Boolean = false | result or body)

11.9.1.2 forall

Results in true if the body expression evaluates to true for each element in the source collection; otherwise, result is false.

  source->forall(iterators | body ) =
  source->iterate(iterators; result : Boolean = true | result and body)

11.9.1.3 isUnique

Results in true if body evaluates to a different value for each element in the source collection; otherwise, result is false.

  source->isUnique (iterator | body) =
  source->collect (iterator | Tuple{iter = Tuple{iterator}, value = body})
  ->forall (x, y | (x.iter <> y.iter) implies (x.value <> y.value))

isUnique may have at most one iterator variable.

11.9.1.4 any

Returns any element in the source collection for which body evaluates to true. If there is more than one element for which body is true, one of them is returned. There must be at least one element fulfilling body, otherwise the result of this IteratorExp is null.
11.9.1.5 one

Results in true if there is exactly one element in the source collection for which body is true.

\[
\text{source->one(\text{iterator} \mid \text{body})} = \\
\text{source->select(\text{iterator} \mid \text{body})-\text{asSequence()}-\text{first()}}
\]

one may have at most one iterator variable.

11.9.1.6 collect

The Collection of elements that results from applying body to every member of the source set. The result is flattened. Notice that this is based on collectNested, which can be of different type depending on the type of source. collectNested is defined individually for each subclass of CollectionType.

\[
\text{source->collect (\text{iterator} \mid \text{body})} = \text{source->collectNested (\text{iterator} \mid \text{body})-flatten()}
\]

collect may have at most one iterator variable.

11.9.2 Set

The standard iterator expression with source of type Set(T) are:

11.9.2.1 select

The subset of set for which expr is true.

\[
\text{source->select(\text{iterator} \mid \text{body})} = \\
\text{source->iterate(\text{iterator}; \text{result} : \text{Set(T)} = \text{Set{}} \mid \\
\quad \text{if body then result-\text{including(\text{iterator})}} \\quad \text{else result} \\
\quad \text{endif) }}
\]

select may have at most one iterator variable.

11.9.2.2 reject

The subset of the source set for which body is false.

\[
\text{source->reject(\text{iterator} \mid \text{body})} = \\
\text{source->select(\text{iterator} \mid \text{not body})}
\]

reject may have at most one iterator variable.

11.9.2.3 collectNested

The Bag of elements which results from applying body to every member of the source set.

\[
\text{source->collectNested(\text{iterator} \mid \text{body})} = \\
\text{source->iterate(\text{iterator}; \text{result} : \text{Bag(body.type)} = \text{Bag{}} \mid \\
\quad \text{result-\text{including(body })})}
\]
collectNested may have at most one iterator variable.

11.9.2.4 sortedBy

Results in the OrderedSet containing all elements of the source collection. The element for which body has the lowest value comes first, and so on. The type of the body expression must have the < operation defined. The < operation must return a Boolean value and must be transitive (i.e., if a < b and b < c then a < c).

source->sortedBy(iterator | body) =
  iterate iterator ; result : OrderedSet(T) : OrderedSet {} |
  if result->isEmpty() then
    result.append(iterator)
  else
    let position : Integer = result->indexOf (result->select (item | body (item) > body (iterator)) ->first() )
    in
    result.insertAt(position, iterator)
  endif

sortBy may have at most one iterator variable.

11.9.3 Bag

The standard iterator expressions with source of type Bag(T) are:

11.9.3.1 select

The sub-bag of the source bag for which body is true.

source->select(iterator | body) =
  source->iterate(iterator; result : Bag(T) = Bag{} |
  if body then result->including(iterator)
  else result
  endif)

select may have at most one iterator variable.

11.9.3.2 reject

The sub-bag of the source bag for which body is false.

source->reject(iterator | body) =
  source->select(iterator | not body)

reject may have at most one iterator variable.

11.9.3.3 collectNested

The Bag of elements which results from applying body to every member of the source bag.

source->collectNested(iterator | body) =
  source->iterate(iterator; result : Bag(body.type) = Bag{} |
  result->including(body ) )
collectNested may have at most one iterator variable.

11.9.3.4 sortedBy

Results in the Sequence containing all elements of the source collection. The element for which body has the lowest value comes first, and so on. The type of the body expression must have the < operation defined. The < operation must return a Boolean value and must be transitive (i.e., if a < b and b < c then a < c).

\[
source->sortedBy(iterator | body) = \\
\text{iterate( iterator ; result : Sequence(T) : Sequence {} |} \\
\text{if result->isEmpty() then} \\
\text{result.append(iterator)} \\
\text{else} \\
\text{let position : Integer = result->indexOf (} \\
\text{result->select (item | body (item) > body (iterator)) ->first() )} \\
\text{in} \\
\text{result.insertAt(position, iterator)} \\
\text{endif}
\]

sortedBy may have at most one iterator variable.

11.9.4 Sequence

The standard iterator expressions with source of type Sequence(T) are:

select(expression : OclExpression) : Sequence(T)

The subsequence of the source sequence for which body is true.

\[
source->select(iterator | body) = \\
source->iterate(iterator; result : Sequence(T) = Sequence {} | \\
\text{if body then result->including(iterator)} \\
\text{else result} \\
\text{endif}
\]

select may have at most one iterator variable.

11.9.4.1 reject

The subsequence of the source sequence for which body is false.

\[
source->reject(iterator | body) = \\
source->select(iterator | not body)
\]

reject may have at most one iterator variable.

11.9.4.2 collectNested

The Sequence of elements that results from applying body to every member of the source sequence.

\[
source->collectNested(iterator | body) = \\
source->iterate(iterator; result : Sequence(body.type) = Sequence {} | \\
\text{iterate( iterator ; result : Sequence(body.type) : Sequence {} |} \\
\text{if result->isEmpty() then} \\
\text{result.append(iterator)} \\
\text{else} \\
\text{let position : Integer = result->indexOf (} \\
\text{result->select (item | body (item) > body (iterator)) ->first() )} \\
\text{in} \\
\text{result.insertAt(position, iterator)} \\
\text{endif}
\]

\[
sortedBy may have at most one iterator variable.
\]
result->append(body )

**collectNested** may have at most one iterator variable.

### 11.9.4.3 sortedBy

Results in the Sequence containing all elements of the `source` collection. The element for which `body` has the lowest value comes first, and so on. The type of the `body` expression must have the `<` operation defined. The `<` operation must return a Boolean value and must be transitive (i.e., if \( a < b \) and \( b < c \) then \( a < c \)).

\[
\text{source->sortedBy(iterator | body) =}
\]

iterate( iterator ; result : Sequence(T) : Sequence {} |
  if result->isEmpty() then
    result.append(iterator)
  else
    let position : Integer = result->indexOf (result->select (item | body (item) > body (iterator)) ->first() )
in
    result.insertAt(position, iterator)
  endif
)

**sortedBy** may have at most one iterator variable.

### 11.9.5 OrderedSet

The standard iterator expressions with source of type OrderedSet(T) are:

**select**(*expression : OclExpression*) : OrderedSet(T)

The ordered set of the source ordered set for which body is true

\[
\text{source->select(iterator | body) =}
\]

iterate( iterator ; result : OrderedSet(T) = OrderedSet{} |
  if body then result->including(iterator)
  else result
  endif)

**select** may have at most one iterator variable.

**reject** (*expression : OclExpression*) : OrderedSet(T)

The ordered set of the source ordered set for which body is false.

\[
\text{source->reject(iterator | body) =}
\]

source->select(iterator | not body)

**reject** may have at most one iterator variable.

**collectNested** (*expression : OclExpression*) : Sequence(T)

The sequence of elements that results from applying `body` to every member of the source ordered set.
source->collectNested(iterator | body) =
    source->iterate(iterator; result : Sequence(body.type) = Sequence{} | 
    result->append(body ))

collectNested may have at most one iterator variable.

sortedBy (expression : OclExpression) : OrderedSet(T)

Results in the ordered set containing all elements of the source collection. The element for which body has the lowest value comes first, and so on. The type of the body expression must have the < operation defined. The < operation must return a Boolean value and must be transitive (i.e., if a < b and b < c, then a < c).

source->sortedBy(iterator | body) =
    iterate(iterator; result : OrderedSet(T) : OrderedSet {} | 
    if result->isEmpty() then 
        result.append(iterator) 
    else 
        let position : Integer = result->indexOf ( 
            result->select (item | body (item) > body (iterator)) ->first() ) 
        in result.insertAt(position, iterator) 
    endif)

sortedBy may have at most one iterator variable.
12 The Use of OCL Expressions in UML Models

12.1 Introduction

This clause describes the various manners in which OCL expressions can be used in UML models.

In principle, everywhere in the UML specification where the term *expression* is used, an OCL expression can be used (e.g., for invariants, preconditions, and postconditions), but other placements are possible too. The meaning of the value, which results from the evaluation of the OCL expression, depends on its placement within the UML model.

In this specification the structure of an expression, and its evaluation are separated from the usage of the expression. Clause 8 (“Abstract Syntax”) defines the structure of an expression. In Clause 9 (“Concrete Syntax”) it was already noted that the contents of the name space environment of an OCL expression are fully determined by the placement of the OCL expression in the model. In that clause an inherited attribute *env* was introduced for every production rule in the attribute grammar to represent this name space environment.

This sub clause specifies a number of predefined places where OCL expressions can be used, their associated meaning, and the contents of the name space environment. The modeler has to define his/her own meaning if OCL is used at a place in the UML model that is not defined in this sub clause.

For every occurrence of an OCL expression three things need to be separated: the placement, the contextual classifier, and the self instance of an OCL expression.

- **The placement** is the position where the OCL expression is used in the UML model (e.g., as invariant connected to class Person).
- **The contextual classifier** defines the namespace in which the expression is evaluated. For example, the contextual classifier of a precondition is the classifier that is the owner of the operation for which the precondition is defined. Visible within the precondition are all model elements that are visible in the contextual classifier.
- **The self instance** is the reference to the object that evaluates the expression. It is always an instance of the contextual classifier. Note that evaluation of an OCL expression may result in a different value for every instance of the contextual classifier.

In the next sub clause a number of placements are stated explicitly. For each, the contextual classifier is defined and well-formedness rules are given that exactly define the place where the OCL expression is attached to the UML model.

12.2 The ExpressionInOcl Type

Because in the abstract syntax `OclExpression` is defined recursively, we need a new metaclass to represent the top of the abstract syntax tree that represents an OCL expression. This metaclass is called `ExpressionInOcl`, and it is defined to be a subclass of the `Expression` metaclass from the UML core, as shown in Figure 12.1. In UML the `Expression` metaclass has an attribute language that may have the value ‘OCL.’ The body attribute contains a text representation of the actual expression. The `bodyExpression` association of `ExpressionInOcl` is an association to the OCL expression as represented by the OCL Abstract syntax metamodel. The `body` attribute (inherited from `Expression`) may still be used to store the string representation of the OCL expression. The language attribute (also inherited from `Expression`) has the value ‘OCL.’
12.2.1 ExpressionInOcl

An expression in OCL is an expression that is written in OCL. The value of the language attribute is therefore always equal to ‘OCL.’

Associations

| bodyExpression | The bodyExpression is an OclExpression that is the root of the actual OCL expression, which is described fully by the OCL abstract syntax metamodel. |
| contextVariable | The ‘self’ variable. The contextual classifier is the type of the ‘self’ variable. |
| resultVariable | The ‘result’ variable representing the value to be returned by the operation. |
| parameterVariable | The variables representing the owned parameters of the current operation. |
| generatedType | Types, such as collection types, that are created on demand by OCL to serve as the types of OclExpressions in the bodyExpression. |

12.3 Well-formedness Rules

12.3.1 ExpressionInOcl

[3] [1] This expression is always written in OCL

context ExpressionInOcl

inv: language = ‘OCL’
12.4 Standard Placements of OCL Expressions

This sub clause defines the standard places where OCL expressions may occur, and defines for each case the value for the contextual classifier. Note that this list of places is not exhausting, and can be enhanced.

12.4.1 How to Extend the Use of OCL at Other Places

At many places in the UML where an Expression is used, one can write this expression in OCL. To define the use of OCL at such a place, the main task is to define what the contextual classifier is. When that is given, the OCL expression is fully defined. This sub clause defines a number of often used placements of OCL expressions.

12.5 Definition

A definition constraint is a constraint that is linked to a Classifier. It may only consist of one or more LetExps. The variable or function defined by the Let expression can be used in an identical way as an attribute or operation of the Classifier. Their visibility is equal to that of a public attribute or operation. The purpose of a definition constraint is to define reusable sub-expressions for use in other OCL expressions.

The placement of a definition constraint in the UML metamodel is shown in Figure 12.2. The following well-formedness rule must hold. This rule also defines the value of the contextual Classifier.

![Diagram of OCL expression used as definition or invariant]

**Figure 12.2 - Situation of Ocl expression used as definition or invariant**

12.5.1 Well-formedness Rules

[4] [1] The ExpressionInOcl is a definition constraint if it has the stereotype «definition» (A) and the constraint is attached to only one model element (B) and the constraint is attached to a Classifier (C).

```plaintext
context ExpressionInOcl
  def: isDefinitionConstraint : Boolean =
    self.constraint.stereotype.name = 'definition' -- A
    and
    self.constraint.constrainedElement->size() = 1 -- B
    and
    self.constraint.constrainedElement.any(true).oclIsKindOf(Classifier) -- C
```

© ISO/IEC 2012 - All rights reserved 177
For a definition constraint the contextual classifier is the constrained element.

context ExpressionInOcl
inv: isDefinitionConstraint implies
   contextualClassifier =
       self.constraint.constrainedElement.any(true).oclAsType(Classifier)

Inside a definition constraint the use of @pre is not allowed.

context ExpressionInOcl
inv: --

12.6 Invariant

An invariant constraint is a constraint that is linked to a Classifier. The purpose of an invariant constraint is to specify invariants for the Classifier. An invariant constraint consists of an OCL expression of type Boolean. The expression must be true for each instance of the classifier at any moment in time. Only when an instance is executing an operation, this does not need to evaluate to true.

The placement of an invariant constraint in the UML metamodel is equal to the placement of a definition constraint, which is shown in Figure 12.3. The following well-formedness rule must hold. This rule also defines the value of the contextual Classifier.

12.6.1 Well-formedness rules

The constraint has the stereotype «invariant» (A) and the constraint is attached to only one model element (B) the constraint is attached to a Classifier (C). The contextual classifier is the constrained element and the type of the OCL expression must be Boolean.

context ExpressionInOcl
inv: self.constraint.stereotype.name = 'invariant' -- A
   and
   self.constraint.constrainedElement->size() = 1 -- B
   and
   self.constraint.constrainedElement.any(true).oclIsKindOf(Classifier) -- C
   implies
   contextualClassifier =
       self.constraint.constrainedElement->any(true).oclAsType(Classifier)
   and
   self.bodyExpression.type.name = 'Boolean'

Inside an invariant constraint the use of @pre is not allowed.

context ExpressionInOcl
inv: --
12.7 Precondition

A precondition is a constraint that may be linked to an Operation of a Classifier. The purpose of a precondition is to specify the conditions that must hold before the operation executes. A precondition consists of an OCL expression of type Boolean. The expression must evaluate to true whenever the operation starts executing, but only for the instance that will execute the operation.

The placement of a precondition in the UML metamodel is shown in Figure 12.4. The following well-formedness rule must hold. This rule also defines the value of the contextual Classifier.

\[\text{context Expression} \]
\[\text{inv: self.constraint.stereotype.name = 'precondition' -- A} \]
\[\text{and} \]
\[\text{self.constraint.constrainedElement->size() = 1 -- B} \]
\[\text{and} \]
\[\text{self.constraint.constrainedElement->any(true).oclIsKindOf(BehavioralFeature) -- C} \]
\[\text{and} \]
\[\text{self.constraint.constrainedElement->any(true) -- D} \]
\[\text{.oclAsType(BehavioralFeature).owner->size() = 1} \]
\[\text{implies} \]
\[\text{contextualClassifier =} \]
\[\quad \text{self.constraint.constrainedElement->any(true)} \]
\[\quad \text{.oclAsType(BehavioralFeature).owner} \]
\[\text{and} \]
\[\text{self.bodyExpression.type.name = 'Boolean'} \]

Figure 12.3 - An OCL ExpressionInOcl used as a pre- or postcondition

12.7.1 Well-formedness rules

[9] [1] The Constraint has the stereotype «precondition» (A), and is attached to only one model element (B), and to a BehavioralFeature (C), which has an owner (D). The contextual classifier is the owner of the operation to which the constraint is attached, and the type of the OCL expression must be Boolean.
12.7.2 Postcondition

Like a precondition, a postcondition is a constraint that may be linked to an Operation of a Classifier. The purpose of a postcondition is to specify the conditions that must hold after the operation executes. A postcondition consists of an OCL expression of type Boolean. The expression must evaluate to true at the moment that the operation stops executing, but only for the instance that has just executed the operation. Within an OCL expression used in a postcondition, the “@pre” mark can be used to refer to values at precondition time. The variable result refers to the return value of the operation if there is any.

The placement of a postcondition in the UML metamodel is equal to the placement of a precondition, which is shown in Figure 12.4. The following well-formedness rule must hold. This rule also defines the value of the contextual Classifier.

12.7.3 Well-formedness rules

The Constraint has the stereotype «postcondition» (A), and it is attached to only one model element (B), that is a BehavioralFeature (C), which has an owner (D). The contextual classifier is the owner of the operation to which the constraint is attached, and the type of the OCL expression must be Boolean.

context Expression
inv: self.constraint.stereotype.name = ‘postcondition’                                -- A
and
self.constraint.constrainedElement->size() = 1                                     -- B
and
self.constraint.constrainedElement->any(true).oclIsKindOf(BehavioralFeature)     -- C
and
self.constraint.constrainedElement->any(true)                                     -- D
  .oclAsType(BehavioralFeature).owner->size() = 1
implies
  contextualClassifier =
    self.constraint.constrainedElement->any().oclAsType(BehavioralFeature).owner
  and
  self.bodyExpression.type.name = ‘Boolean’

12.8 Initial Value Expression

An initial value expression is an expression that may be linked to an Attribute of a Classifier, or to an AssociationEnd. An OCL expression acting as the initial value of an attribute must conform to the defined type of the attribute. An OCL expression acting as the initial value of an association end must conform to the type of the association end. For instance, the type of the attached Classifier when the multiplicity is maximum one, or OrderedSet with element type the type of the attached Classifier when the multiplicity is maximum more than one.

The OCL expression is evaluated at the creation time of the instance that owns the attribute for this created instance in the case of an initial value for an attribute. In the case of an initial value for an association end, the OCL expression is evaluated at the creation time of the instance of the Classifier at the other end(s) of the association.
The placement of an attribute initial value in the UML metamodel is shown in Figure 12.5. The following well-formedness rule must hold. This rule also defines the value of the contextual Classifier.

**Note** - The placement of an initial value of an association end is dependent upon the UML 2.0 metamodel. So are the well-formedness rules for this case.

### 12.8.1 Well-formedness rules

[12] [1] The Expression is the initial value of an attribute (A), and the Attribute has an owner (B). The contextual classifier is the owner of the attribute, and the type of the OCL expression must conform to the type of the attribute.

[13]

```plaintext
context ExpressionInOcl
  inv: self.attribute->notEmpty() \-- A
  and
  self.attribute.owner->size() = 1 \-- B
  implies
  contextualClassifier = self.attribute.owner
  and
  self.bodyExpression.type.conformsTo(self.attribute.type)
```

[14] [2] Inside an initial attribute value the use of `@pre` is not allowed.

```plaintext
context ExpressionInOcl
  inv: -- TBD
```

![Diagram](image-url)  
**Figure 12.4** - Expression used to define the initial value of an attribute
12.9 Derived Value Expression

A derived value expression is an expression that may be linked to an Attribute of a Classifier, or to an AssociationEnd. An OCL expression acting as the derived value of an attribute must conform to the defined type of the attribute. An OCL expression acting as the derived value of an association end must conform to the type of the association end. For instance, the type of the attached Classifier when the multiplicity is maximum one, or OrderedSet with element type the type of the attached Classifier when the multiplicity is maximum more than one.

A derived value expression is an invariant that states that the value of the attribute or association end must always be equal to the value obtained from evaluating the expression.

**Note** - The placement of a derived value expression is dependent upon the UML 2.0 metamodel. So are the well-formedness rules for this case.

12.10 Operation Body Expression

A body expression is an expression that may be linked to an Operation of a Classifier, that is marked Query operation. An OCL expression acting as the body of an operation must conform to the result type of the operation. Evaluating the body expression gives the result of the operation at a certain point in time.

**Note** - The placement of an operation body expression is dependent upon the UML 2.0 metamodel. So are the well-formedness rules for this case.

12.11 Guard

A guard is an expression that may be linked to a Transition in a StateMachine. An OCL expression acting as the guard of a transition restricts the transition. An OCL expression acting as value of a guard is of type Boolean. The expression is evaluated at the moment that the transition attached to the guard is attempted.

The placement of a guard in the UML metamodel is shown in Figure 12.5. The following well-formedness rule must hold. In order to state the rule a number of additional operations are defined. The rule also defines the value of the contextual Classifier.

![Figure 12.5 - An OCL expression used as a Guard expression](image-url)
12.11.1 Well-formedness rules

[15] [1] The statemachine in which the guard appears must have a context (A), that is a Classifier (B). The contextual classifier is the owner of the statemachine, and the type of the OCL expression must be Boolean.

context ExpressionInOcl
inv: not self.guard.transition.getStateMachine().context.oclIsUndefined() -- A
and
self.guard.transition.getStateMachine().context.oclIsKindOf(Classifier) -- B
implies
contextualClassifier =
self.guard.transition.getStateMachine().context.oclAsType(Classifier)
and
self.bodyExpression.type.name = ‘Boolean’

[16][2] Inside a guard the use of @pre is not allowed.

12.12 Concrete Syntax of Context Declarations

This sub clause describes the concrete syntax for specifying the context of the different types of usage of OCL expressions. It makes use of grammar rules defined in Clause 9 (“Concrete Syntax”). Here too, every production rule is associated to the abstract syntax by the type of the attribute (ast). However, we must sometimes refer to the abstract syntax of the UML to find the right type for each production.

Visibility rules etc. must be defined in the UML metamodel. Here we assume that every classifier has an operation `visibleElements()`, which returns an instance of type Environment, as defined in Clause 9 (“Concrete Syntax”).

**Note** - The context declarations as described in this sub clause are not needed when the OCL expressions are attached directly to the UML model. This concrete syntax for context declarations is only there to facilitate separate OCL expressions in text files.

Because of the assumption that the concrete syntax below is used separate from the UML model, we assume the existence of an operation `getClassifier()` on the UML model that allows us to find a Classifier anywhere in the corresponding model. The signature of this operation is defined as follows:

```
context Model::findClassifier( pathName : Sequence(String) ) : Classifier
```

The `pathName` need not be a fully qualified name (it may be), as long as it can uniquely identify the classifier somewhere in the UML model. If a classifier name occurs more than once, it needs to be qualified with its owning package (recursively) until the qualified name is unique. If more than one classifier is found, the operation returns invalid. The variable `Model` is used to refer to the UML Model. It is used as `Model.findClassifier()`.

Likewise, we assume the existence of an operation `getPackage()` on the UML model that allows us to find a Package anywhere in the corresponding model. The signature of this operation is defined as follows:

```
context Model::findPackage( pathName : Sequence(String) ) : Package
```

In this case the `pathName` needs to be a fully qualified name.
ISO/IEC 19507:2012(E)

Note - The rules for the synthesized and inherited attributes associated with the grammar all depend upon the UML 2.0 metamodel. They cannot be written until this metamodel has been stabilized. Therefore only the grammar rules are given.

12.12.1 packageDeclarationCS
This production rule represents a package declaration.
[17] [A] packageDeclarationCS ::= “package” pathNameCS contextDeclCS* “endpackage”
[18] [B] packageDeclarationCS ::= contextDeclCS*

12.12.2 contextDeclarationCS
This production rule represents all different context declarations.
[19] [A] contextDeclarationCS ::= propertyContextDeclCS
[20] [C] contextDeclarationCS ::= classifierContextDeclCS
[21] [D] contextDeclarationCS ::= operationContextDeclCS

12.12.3 propertyContextDeclCS
This production rule represents a context declaration for expressions that can be coupled to a property. The path name refers to the “owner” of the property, the simple name refers to its name, the type states its type.
[22] propertyContextDeclCS ::= ‘context’ pathNameCS ‘::’ simpleName’::’ typeCS initOrDerValueCS

12.12.4 initOrDerValueCS
This production rule represents an initial or derived value expression.
[23] [A] initOrDerValueCS[1] ::= ‘init’ ‘::’ OclExpression
    initOrDerValueCS[2]?
[24] [B] initOrDerValueCS[1] ::= ‘derive’ ‘::’ OclExpression
    initOrDerValueCS[2]?

12.12.5 classifierContextDeclCS
This production rule represents a context declaration for expressions that can be coupled to classifiers. The variable declaration to the classifier context is ‘self’ for the A form and explicitly specified for the B form.
[25] [A] classifierContextDeclCS ::= ‘context’ pathNameCS invOrDefCS
[26] [B] classifierContextDeclCS ::= ‘context’ simpleNameCS ‘::’ pathNameCS invOrDefCS

12.12.6 invOrDefCS
This production rule represents an invariant or definition.
[27] [A] invOrDefCS[1] ::= ‘inv’ (simpleNameCS)? ‘::’ OclExpressionCS
    invOrDefCS[2]
[28] [B] invOrDefCS[1] ::= (‘static’)? ‘def’ (simpleNameCS)? ‘::’ defExpressionCS
    invOrDefCS[2]
12.12.7 defExpressionCS

This production rule represents a definition expression. The defExpressionCS nonterminal has the purpose of defining additional attributes or operations in OCL. They map directly to a UML attribute or operation with a constraint that defines the derivation of the attribute or operation result value. Note that VariableDeclarationCS has been defined in Clause 9.

[29] [A] defExpressionCS ::= VariableDeclarationCS '=' OclExpression
[30] [B] defExpressionCS ::= operationCS '=' OclExpression

12.12.8 operationContextDeclCS

This production rule represents a context declaration for expressions that can be coupled to an operation.

[31] operationContextDeclCS ::= ‘context’ operationCS prePostOrBodyDeclCS

12.12.9 prePostOrBodyDeclCS

This production rule represents a pre- or postcondition or body expression.

[32] [A] prePostOrBodyDeclCS[1] ::= ‘pre’ (simpleNameCS)? ‘:’ OclExpressionCS
    prePostOrBodyDeclCS[2]?
[33] [B] prePostOrBodyDeclCS[1] ::= ‘post’ (simpleNameCS)? ‘:’ OclExpressionCS
    prePostOrBodyDeclCS[2]?
[34] [C] prePostOrBodyDeclCS[1] ::= ‘body’ (simpleNameCS)? ‘:’ OclExpressionCS
    prePostOrBodyDeclCS[2]?

12.12.10 operationCS

This production rule represents an operation in a context declaration or definition expression.

[35] [A] operationCS ::= pathNameCS ‘::’ simpleNameCS (‘(‘ parametersCS? ‘)’ ‘:’ typeCS?
[36] [B] operationCS ::= simpleNameCS (‘(‘ parametersCS? ‘)’ ‘:’ typeCS?

12.12.11 parametersCS

This production rule represents the formal parameters of an operation.

[38]
13 The Basic OCL and Essential OCL

13.1 Introduction

This clause describes the connections between the OCL and UML metamodels.

BasicOCL is the package exposing the minimal OCL required to work with Core::Basic.

EssentialOCL is the package exposing the minimal OCL required to work with EMOF. EssentialOCL depends on the EMOF Package. It references explicitly the EMOF classes: Property, Operation, Parameter, TypedElement, Type, Class, DataType, Enumeration, PrimitiveType, and EnumerationLiteral.

EssentialOCL is built from Core::Basic and BasicOcl using package merge with copy semantics in a similar way as EMOF is built from Core::Basic. Structurally there is no difference between BasicOCL and EssentialOCL. For this reason we provide in this clause a unique set of diagrams that defines the abstract syntax for both packages.

For convenience, because BasicOCL (respectively EssentialOCL) is - conceptually a subset of the complete OCL language for UML superstructure, we will not repeat or redefine here all the class descriptions and the well-formedness rules defined in the other clauses. When applicable, all these definitions are to be re-interpreted in the specific context of Core::Basic (respectively EMOF). The sub clause “OCL adaptation for meta-modeling” defines specific rules for the re-interpretation of the “complete” OCL, whereas the “Diagrams” sub clause provides the complete diagrams defining the BasicOCL (respectively EssentialOCL) abstract syntax.

13.2 OCL Adaptation for Metamodeling

We provide below a set of rules and conventions that are applied to define BasicOCL (and consequently EssentialOCL) from the OCL defined for UML superstructure - called “complete OCL” in this sub clause.

1. The following metaclasses defined in complete OCL are not part of BasicOCL (and EssentialOCL):
   - MessageType
   - ElementType
   - AssociationClassCallExp
   - MessageExp
   - StateExp
   - UnspecifiedValueExp

   Any well-formedness rules defined for these classes are consequently not part of the definition of Basic OCL.

   The properties NavigationCallExp::qualifier and NavigationCallExp::navigationSource are suppressed since not needed in this context.

2. Core::Basic does not contain the intermediate notion of Classifier but uses instead directly the Type notion as the base class for the type system. Consequently, any reference to the Classifier class in the complete OCL specification has to be re-interpreted as a reference to the Type class.

3. The following operations do not form part of Essential OCL
4. The following names are not reserved or restricted in Essential OCL

```ocl
@pre
body
context
def
derive
defpackage
init
inv
package
post
pre
static
```

**Note** - It is expected that further revisions of this specification will provide explicitly the complete set of well-formedness rules and additional operations that apply to Core::Basic - to replace the lazy re-interpretation statement we are using here.

5. In complete OCL, TupleType has DataType as base type. In BasicOCL Tuple also has Class as base type so that the attributes of the tuple can be defined in the same way as in complete OCL - as Property instances.

6. In complete OCL, pre-defined types have pre-defined operations defined in the standard library. However, a DataType in Core::Basic cannot define such operations since it inherits from Type (and not from Class). For all data types and special types - like VoidType, InvalidType, and AnyType - the following convention is used: in the standard library the instance representing the pre-defined type is accompanied with a class instance with the same name that holds the operations. An access to an operation of the pre-defined type implies an access to the operation of the complementary class instance.

7. The EMOF Reflection capability is not merged to the metamodel. AnyType plays the role of Object. At instance level, reflection is provided by the oclIsKindOf(), oclIsTypeOf(), and oclType() operations.

### 13.3 Diagrams

The diagrams below completely define the abstract syntax of BasicOCL (respectively EssentialOCL). The classes that are not imported from Core::Basic (respectively EMOF) are shown with a transparent fill color.

Annex A: Semantics

(informative)

A.1 General

This annex formally defines the syntax and semantics of OCL and is organized as follows. Sub clause A.1 defines the concept of object models. Object models provide information used as context for OCL expressions and constraints. Sub clause A.2 defines the type system of OCL and the set of standard operations. Finally, sub clause A.3 defines the syntax and semantics of OCL expressions.

A.2 Object Models

In this sub clause, the notion of an object model is formally defined. An object model provides the context for OCL expressions and constraints. A precise understanding of object models is required before a formal definition of OCL expressions can be given. Sub clause A.1.1 proceeds with a formal definition of the syntax of object models. The semantics of object models is defined in sub clause A.1.2. This sub clause also defines the notion of system states as snapshots of a running system.

A.2.1 Syntax of Object Models

In this sub clause, we formally define the syntax of object models. Such a model has the following components:

- a set of classes
- a set of attributes for each class
- a set of operations for each class
- a set of associations with role names and multiplicities
- a generalization hierarchy over classes

Additionally, types such as Integer, String, Set(Real) are available for describing types of attributes and operation parameters. In the following, each of the model components is considered in detail. The following definitions are combined in A.2.1.7, ‘Formal Syntax’ to give a complete definition of the syntax of object models. For naming model components, we assume in this sub clause an alphabet \( A \) and a set of finite, non-empty names \( N \subseteq A^+ \) over alphabet \( A \) to be given.

A.2.1.1 Types

Types are considered in depth in sub clause A.2. For now, we assume that there is a signature \( \Sigma = (T, \Omega) \) with \( T \) being a set of type names, and \( \Omega \) being a set of operations over types in \( T \). The set \( T \) includes the basic types UnlimitedNatural, Integer, Real, Boolean, and String. These are the predefined basic types of OCL. All type domains include \( \perp \), an invalid value, and \( \epsilon \), a null value, that allow one to operate respectively with invalid and undefined values. The unlimited natural
domain includes $\infty$, the unlimited value. Operations in $\Omega$ include, for example, the usual arithmetic operations $+, -, \_, /$, etc. for integers. Furthermore, collection types are available for describing collections of values, for example, $Set(String)$, $Bag(Integer)$, and $Sequence(Real)$. Structured values are described by tuple types with named components, for example, $Tuple(name:String, age:Integer)$.

A.2.1.2 Classes

The central concept of UML for modeling entities of the problem domain is the class. A class provides a common description for a set of objects sharing the same properties.

Definition A.1 (Classes)

The set of classes is a finite set of names $CLASS \subseteq N$. Each class $c \in CLASS$ induces an object type $t_c \in T$ having the same name as the class. A value of an object type refers to an object of the corresponding class. The main difference between classes and object types is that the interpretation of the latter includes a special undefined value and a special invalid value.

Note that for a definition of the semantics of OCL, UML’s distinction between classes and interfaces does not matter. OCL specifies constraints for instances of a given interface specification. Whether this specification is stated in the form of a class or interface definition makes no difference.

A.2.1.3 Attributes

Attributes are part of a class declaration in UML. Objects are associated with attribute values describing properties of the object. An attribute has a name and a type specifying the domain of attribute values.

Definition A.2 (Attributes)

Let $t \in T$ be a type. The attributes of a class $c \in CLASS$ are defined as a set $ATT_c$ of signatures $a : t_c \rightarrow t$ where the attribute name $a$ is an element of $N$, and $t_c \in T$ is the type of class $c$.

All attributes of a class have distinct names. In particular, an attribute name may not be used again to define another attribute with a different type.

$$\forall t, t' \in T: (a : t_c \rightarrow t \in ATT_c \text{ and } a : t_c \rightarrow t' \in ATT_c) \Rightarrow t = t'$$

Attributes with the same name may, however, appear in different classes that are not related by generalization. Details are given in sub clause A.1.1.6 where we discuss generalization. The set of attribute names and class names need not be disjoint.

A.2.1.4 Operations

Operations are part of a class definition. They are used to describe behavioral properties of objects. The effect of an operation may be specified in a declarative way with OCL pre- and postconditions. Section A.5 discusses pre- and postconditions in detail. Furthermore, operations performing computations without side effects can be specified with OCL. In this case, the computation is determined by an explicit OCL expression. This is also discussed in section A.5. Here, we focus on the syntax of operation signatures declaring the interface of user-defined operations. In contrast, other kinds of operations which are not explicitly defined by a modeler are, for example, navigation operations derived from associations. These are discussed in the next sub clause and in “Ocl Types and Operations” on page 201.
Definition A.3 (Operations)

Let $t$ and $t_1, \ldots, t_n$ be types in $T$. Operations of a class $c \in \text{CLASS}$ with type $t_c \in T$ are defined by a set $\text{OP}_c$ of signatures $\omega: t_c \times t_1 \times \cdots \times t_n \to t$ with operation symbols $\omega$ being elements of $N$.

The name of an operation is determined by the symbol $\omega$. The first parameter $t_c$ denotes the type of the class instance to which the operation is applied. An operation may have any number of parameters but only a single return type. In general, UML allows multiple return values. We currently do not support this feature in OCL.

A.2.1.5 Associations

Associations describe structural relationships between classes. Generally, classes may participate in any number of associations, and associations may connect two or more classes.

Definition A.4 (Associations)

The set of associations is given by

i. a finite set of names $\text{ASSOC} \in N$,

ii. a function $\text{associates}: \text{ASSOC} \to \text{CLASS}^+$

$\text{ass} \to \langle c_1, \ldots, c_n \rangle$ with $(n \geq 2)$

The function associates maps each association name $\text{ass} \in \text{ASSOC}$ to a finite list $\langle c_1, \ldots, c_n \rangle$ of classes participating in the association. The number $n$ of participating classes is also called the degree of an association; associations with degree $n$ are called $n$-ary associations. For many problems the use of binary associations is often sufficient. A self-association (or recursive association) $sa$ is a binary association where both ends of the association are attached to the same class $c$ such that $\text{associates}(sa) = \langle c, c \rangle$. The function associates does not have to be injective. Multiple associations over the same set of classes are possible.

Role Names

Classes may appear more than once in an association each time playing a different role. For example, in a self-association PhoneCall on a class Person we need to distinguish between the person having the role of a caller and another person being the callee. Therefore we assign each class participating in an association a unique role name. Role names are also important for OCL navigation expressions. A role name of a class is used to determine the navigation path in this kind of expression.

Definition A.5 (Role Names)

Let $\text{ass} \in \text{ASSOC}$ be an association with $\text{associates}(\text{ass}) = \langle c_1, \ldots, c_n \rangle$. Role names for an association are defined by a function

$\text{roles}: \text{ASSOC} \to N^+$

$\text{ass} \to \langle r_1, \ldots, r_n \rangle$ with $(n \geq 2)$
where all role names must be distinct, i.e.,
\[ \forall i, j \in \{1, \ldots, n\} : i \neq j \Rightarrow r_i \neq r_j. \]

The function \( \text{roles}(as) = (r_1, \ldots, r_n) \) assigns each class \( c_i \) for \( 1 \leq i \leq n \) participating in the association a unique role name \( r_j \). If role names are omitted in a class diagram, implicit names are constructed in UML by using the name of the class at the target end and changing its first letter to lower case. As mentioned above, explicit role names are mandatory for self-associations.

Additional syntactical constraints are required for ensuring the uniqueness of role names when a class is part of many associations. We first define a function participating that gives the set of associations a class participates in.

\[
\text{participating} : \quad \text{CLASS} \rightarrow \mathcal{P}(\text{ASSOC})
\]
\[
\text{participating} : \quad c \rightarrow \{ as | as \in \text{ASSOC} \land \text{associates}(as) = (c_1, \ldots, c_n) \}
\]
\[
\land \quad \exists i \in \{1, \ldots, n\} : c_i = c \}
\]

The following function \( \text{navends} \) gives the set of all role names reachable (or \textit{navigable}) from a class over a given association.

\[
\text{navends} : \quad \text{CLASS} \times \text{ASSOC} \rightarrow \mathcal{P}(N)
\]
\[
\text{navends} : \quad (c, as) \rightarrow \{ r | \text{associates}(as) = (c_1, \ldots, c_n) \}
\]
\[
\land \quad \text{roles}(as) = (r_1, \ldots, r_n) \}
\]
\[
\land \quad \exists i, j \in \{1, \ldots, n\} : (i \neq j \land c_i = c \land r_j = r) \}
\]

The set of role names that are reachable from a class along all associations the class participates in can then be determined by the following function.

\[
\text{navends}(c) : \quad \text{CLASS} \rightarrow \mathcal{P}(N)
\]
\[
\text{navends}(c) : \quad c \rightarrow \bigcup_{as \in \text{participating}(c)} \text{navends}(c, as)
\]

\textbf{Multiplicities}

An association specifies the possible existence of links between objects of associated classes. The number of links that an object can be part of is specified with \textit{multiplicities}. A multiplicity specification in UML can be represented by a set of natural numbers.
Definition A.6 (Multiplicities)

Let \( \text{asso} \in \text{ASSOC} \) be an association with \( \text{associates(asso)} = \langle c_1, \ldots, c_n \rangle \). The function \( \text{multiplicities(asso)} = \langle M_1, \ldots, M_n \rangle \) assigns each class \( c_i \) participating in the association a non-empty set \( M_i \subseteq \mathbb{N}_0 \) with \( M_i \neq \{0\} \) for all \( 1 \leq i \leq n \).

The precise meaning of multiplicities is defined as part of the interpretation of object models in “Interpretation of Object Models” on page 200.

Remark: Aggregation and Composition

Special forms of associations are aggregation and composition. In general, aggregations and compositions impose additional restrictions on relationships. An aggregation is a special kind of binary association representing a part-of relationship. The aggregate is marked with a hollow diamond at the association end in class diagrams. An aggregation implies the constraint that an object cannot be part of itself. Therefore, a link of an aggregation may not connect the same object. In case of chained aggregations, the chain may not contain cycles.

An even stronger form of aggregation is composition. The composite is marked with a filled diamond at the association end in class diagrams. In addition to the requirements for aggregations, a part may only belong to at most one composite.

These seemingly simple concepts can have quite complex semantic issues [AFGP96, Mot96, Pri97, GR99, HSB99, BHS99, BHSOG01]. Here, we are concerned only with syntax. The syntax of aggregations and compositions is very similar to associations. Therefore, we do not add an extra concept to our formalism. As a convention, we always use the first component in an association for a class playing the role of an aggregate or composite. The semantic restrictions then have to be expressed as an explicit constraint. A systematic way for mapping aggregations and compositions to simple associations plus OCL constraints is presented in [GR99].

A.2.1.6 Generalization

A generalization is a taxonomic relationship between two classes. This relationship specializes a general class into a more specific class. Specialization and generalization are different views of the same concept. Generalization relationships form a hierarchy over the set of classes.

Definition A.7 (Generalization Hierarchy)

A generalization hierarchy \( \prec \) is a partial order on the set of classes \( \text{CLASS} \).

Pairs in \( \prec \) describe generalization relationships between two classes. For classes \( c_1, c_2 \in \text{CLASS} \) with \( c_1 \prec c_2 \), the class \( c_1 \) is called a child class of \( c_2 \), and \( c_2 \) is called a parent class of \( c_1 \).

Full Descriptor of a Class

A child class implicitly inherits attributes, operations, and associations of its parent classes. The set of properties defined in a class together with its inherited properties is called a full descriptor in UML. We can formalize the full descriptor in our framework as follows. First, we define a convenience function for collecting all parents of a given class.
The full set of attributes of class $c$ is the set $\text{ATT}_c^*$ containing all inherited attributes and those that are defined directly in the class.

$$\text{ATT}_c^* = \text{ATT}_c \cup \bigcup_{c' \in \text{parents}(c)} \text{ATT}_{c'}$$

We define the set of inherited user-defined operations analogously.

$$\text{OP}_c^* = \text{OP}_c \cup \bigcup_{c' \in \text{parents}(c)} \text{OP}_{c'}$$

Finally, the set of navigable role names for a class and all of its parents is given as follows.

$$\text{navends}^*(c) = \text{navends}(c) \cup \bigcup_{c' \in \text{parents}(c)} \text{navends}(c')$$

**Definition A.8 (Full Descriptor of a Class)**

The full descriptor of a class $c \in \text{CLASS}$ is a structure $\text{FD}_c = (\text{ATT}_c^*, \text{OP}_c^*, \text{navends}^*(c))$ containing all attributes, user-defined operations, and navigable role names defined for the class and all of its parents.

The UML standard requires that properties of a full descriptor must be distinct. For example, a class may not define an attribute that is already defined in one of its parent classes. These constraints are captured more precisely by the following well-formedness rules in our framework. Each constraint must hold for each class $c \in \text{CLASS}$.

1. Attributes are defined in exactly one class.

   $$\forall (a : t_c \rightarrow t, a' : t'_c \rightarrow t' \in \text{ATT}_c^*):$$

   $$(a = a' \Rightarrow t_c = t'_c \land t = t')$$

   (WF-1)

2. In a full class descriptor, an operation may only be defined once. The first parameter of an operation signature indicates the class in which the operation is defined. The following condition guarantees that each operation in a full class descriptor is defined in a single class.

   $$\forall (\omega : t_c \times \ldots \times t_n \rightarrow t, \omega : t'_c \times t_1 \times \ldots \times t_n \rightarrow t' \in \text{OP}_c^*):$$

   $$(t_c = t'_c)$$

   (WF-2)
3. Role names are defined in exactly one class.

\[ \forall c_1, c_2 \in \text{parents}(c) \cup \{c\} : \\
(c_1 \neq c_2 \Rightarrow \text{navends}(c_1) \cap \text{navends}(c_2) = 0) \quad \text{(WF-3)} \]

4. Attribute names and role names must not conflict. This is necessary because in OCL the same notation is used for attribute access and navigation by role name. For example, the expression `self.x` may either be a reference to an attribute `x` or a reference to a role name `x`.

\[ \forall (a : t_c \rightarrow t \in \text{ATT}^*_c) : \forall r \in \text{navends}^*(c) : : \\
(a \neq r) \quad \text{(WF-4)} \]

Note that operations may have the same name as attributes or role names because the concrete syntax of OCL allows us to distinguish between these cases. For example, the expression `self.age` is either an attribute or role name reference, but a call to an operation `age` without parameters is written as `self.age()`.

**A.2.1.7 Formal Syntax**

We combine the components introduced in the previous sub clause to formally define the syntax of object models.

**Definition A.9 (Syntax of Object Models)**

The syntax of an object model is a structure.

\[ M = (\text{CLASS, ATT}_c, \text{OP}_c, \text{ASSOC, associates, roles, multiplicities, } \prec ) \]

where

i. CLASS is a set of classes (Definition A.1).

ii. \(\text{ATT}_c\) is a set of operation signatures for functions mapping an object of class \(c\) to an associated attribute value (Definition A.2).

iii. \(\text{OP}_c\) is a set of signatures for user-defined operations of a class \(c\) (Definition A.3).

iv. ASSOC is a set of association names (Definition A.4).

- (a) associates is a function mapping each association name to a list of participating classes (Definition A.4).
- (b) roles is a function assigning each end of an association a role name (Definition A.5).
- (c) multiplicities is a function assigning each end of an association a multiplicity specification (Definition A.6).

v. \(\prec\) is a partial order on CLASS reflecting the generalization hierarchy of classes (Definitions A.7 and A.8).
A.3 Interpretation of Object Models

In the previous sub clause, the syntax of object models has been defined. An interpretation of object models is presented as follows.

A.3.1 Objects

The domain of a class \( c \in \text{CLASS} \) is the set of objects that can be created by this class and all of its child classes. Objects are referred to by unique object identifiers. In the following, we will make no conceptual distinction between objects and their identifiers. Each object is uniquely determined by its identifier and vice versa. Therefore, the actual representation of an object is not important for our purposes.

Definition A.10 (Object Identifiers)

i. The set of object identifiers of a class \( c \in \text{CLASS} \) is defined by an infinite set \( \text{oid}(c) = \{ c_1, c_2, \ldots \} \)

ii. The domain of a class \( c \in \text{CLASS} \) is defined as \( I_{\text{CLASS}}(c') = \bigcup \{ \text{oid}(c') \mid c' \in \text{CLASS} ^ {c' \preceq c} \} \)

In the following, we will omit the index for a mapping \( I \) when the context is obvious. The concrete scheme for naming objects is not important as long as every object can be uniquely identified, i.e., there are no different objects having the same name. We sometimes use single letters combined with increasing indexes to name objects if it is clear from the context to which class these objects belong.

A.3.1.1 Generalization

The above definition implies that a generalization hierarchy induces a subset relation on the semantic domain of classes. The set of object identifiers of a child class is a subset of the set of object identifiers of its parent classes. In other words, we have

\[
\forall c_1, c_2 \in \text{CLASS} : c_1 \preceq c_2 \Rightarrow I(c_1) \subseteq I(c_2)
\]

From the perspective of programming languages this closely corresponds to the domain-inclusion semantics commonly associated with subtyping and inheritance [CW85]. Data models for object-oriented databases such as the generic OODB model presented in [AHV95] also assume an inclusion semantics for class extensions. This requirement guarantees two fundamental properties of generalizations. First, an object of a child class has (inherits) all the properties of its parent classes because it is an instance of the parent classes. Second, this implies that an object of a more specialized class can be used anywhere where an object of a more general class is expected (principle of substitutability) because it has at least all the properties of the parent classes. In general, the interpretation of classes is pairwise disjoint if two classifiers are not related by generalization and do not have a common child.

A.3.1.2 Links

An association describes possible connections between objects of the classes participating in the association. A connection is also called a link in UML terminology. The interpretation of an association is a relation describing the set of all possible links between objects of the associated classes and their children.

Definition A.11 (Links)

Each association \( as \in \text{ASSOC} \) with \( \text{associates}(as) = \{ c_1, \ldots, c_n \} \) is interpreted as the Cartesian product of the sets of object identifiers of the participating classes: \( I_{\text{ASSOC}}(as) = I_{\text{CLASS}}(c_1) \times \cdots \times I_{\text{CLASS}}(c_n) \). A link denoting a connection between objects is an element \( l_{as} \in I_{\text{ASSOC}}(as) \).
A.3.1.3 System State

Objects, links, and attribute values constitute the state of a system at a particular moment in time. A system is in different states as it changes over time. Therefore, a system state is also called a snapshot of a running system. With respect to OCL, we can in many cases concentrate on a single system state given at a discrete point in time. For example, a system state provides the complete context for the evaluation of OCL invariants. For pre- and postconditions, however, it is necessary to consider two consecutive states.

Definition A.12 (System State)

A system state for a model $M$ is a structure $\sigma(M) = (\sigma_{\text{CLASS}}, \sigma_{\text{ATT}}, \sigma_{\text{ASSOC}})$.

i. The finite sets $\sigma_{\text{CLASS}}(c)$ contain all objects of a class $c \in \text{CLASS}$ existing in the system state:

$$\sigma_{\text{CLASS}}(c) \subseteq \text{oid}(c).$$

ii. Functions $\sigma_{\text{ATT}}$ assign attribute values to each object: $\sigma_{\text{ATT}}(a) : \sigma_{\text{CLASS}}(c) \rightarrow l(t)$ for each $a : t_c \rightarrow t \in \text{ATT}^*$. 

iii. The finite sets $\sigma_{\text{ASSOC}}$ contain links connecting objects. For each $as \in \text{ASSOC}$:

$$\sigma_{\text{ASSOC}}(as) \subseteq \text{ASSOC}(as).$$

A link set must satisfy all multiplicity specifications defined for an association (the function $\pi_i(l)$ projects the $i$th component of a tuple or list $l$, whereas the function $\pi_i(l)$ projects all but the $i$th component):

$$\forall i \in \{1, ..., n\}, \forall l \in \sigma_{\text{ASSOC}}(as) :$$

$$|\{l' | l' \in \sigma_{\text{ASSOC}}(as) \land (\pi_i(l') = (\pi_i(l)))\}| \in \pi_i(\text{multiplicities}(as))$$

A.4 OCL Types and Operations

OCL is a strongly typed language. A type is assigned to every OCL expression and typing rules determine in which ways well-formed expressions can be constructed. In addition to those types introduced by UML models, there are a number of predefined OCL types and operations available for use with any UML model. This sub clause formally defines the type system of OCL. Types and their domains are fixed, and the abstract syntax and semantics of operations is defined.

Our general approach to defining the type system is as follows. Types are associated with a set of operations. These operations describe functions combining or operating on values of the type domains. In our approach, we use a data signature $\Sigma = (T, \Omega)$ to describe the syntax of types and operations. The semantics of types in $T$ and operations in $\Omega$ is defined by a mapping that assigns each type a domain and each operation a function. The definition of the syntax and semantics of types and operations will be developed and extended in several steps. At the end of this sub clause, the complete set of types is defined in a single data signature.

“Basic Types” on page 202 defines the basic types $\text{UnlimitedNatural}$, $\text{Integer}$, $\text{Real}$, $\text{Boolean}$, and $\text{String}$. Enumeration types are defined in “Enumeration Types” on page 206. “Object Types” on page 206 introduces object types that correspond to classes in a model. Collection and tuple types are discussed in “Collection and Tuple Types” on page 209. The special types $\text{OclAny}$ and $\text{OclState}$ are considered in “Special Types” on page 215. “Type Hierarchy” on page 216 introduces subtype relationships forming a type hierarchy. All types and operations are finally summarized in a data signature defined in “Data Signature” on page 217.
A.4.1 Basic Types

Basic types are UnlimitedNatural, Integer, Real, Boolean, and String. The syntax of basic types and their operations is defined by a signature $\Sigma_B = (T_B, \Omega_B)$. $T_B$ is the set of basic types, $\Omega_B$ is the set of signatures describing operations over basic types.

Definition A.13 (Syntax Of Basic Types)

The set of basic types $T_B$ is defined as $T_B = \{\text{UnlimitedNatural}, \text{Integer}, \text{Real}, \text{Boolean}, \text{String}\}$. Next we define the semantics of basic types by mapping each type to a domain.

Definition A.14 (Semantics Of Basic Types)

Let $A^*$ be the set of finite sequences of characters from a finite alphabet $A$. The semantics of a basic type $t \in T_B$ is a function $I$ mapping each type to a set:

- $I(\text{OclInvalid}) = \{\bot\}$
- $I(\text{OclVoid}) = \{\varepsilon, \bot\}$
- $I(\text{Integer}) = \mathbb{Z} \cup \{\varepsilon, \bot\}$
- $I(\text{Real}) = \mathbb{R} \cup \{\varepsilon, \bot\}$
- $I(\text{Boolean}) = \{\text{true}, \text{false}\} \cup \{\varepsilon, \bot\}$
- $I(\text{String}) = A^* \cup \{\varepsilon, \bot\}$
- $I(\text{UnlimitedNatural}) = \mathbb{N} \cup \{\varepsilon, \bot, \infty\}$.

The basic type UnlimitedNatural represents the set of non-negative integers, Integer represents the set of integers, Real the set of real numbers, Boolean the truth values true and false, and String all finite strings over a given alphabet. Each domain also contains two special values $\varepsilon$ and $\bot$. $\varepsilon$ corresponds to the null value, and $\bot$, pronounced bottom, corresponds to the invalid value. These are motivated in the next sub clause. The UnlimitedNatural domain also includes a special value to denote the unlimited natural number.

A.4.1.1 Error Handling

Each domain of a basic type $t$ contains two special values $\varepsilon$ and $\bot$. $\varepsilon$ represents a null or undefined value and $\bot$ an invalid value. These are useful for the following purposes:

1. An undefined or null value may, for example, be assigned to an attribute of an object. In this case the undefined value helps to model the situation where the attribute value is not yet known (for example, the email address of a customer is unknown at the time of the first contact, but will be added later) or does not apply to this specific object instance (e.g., the customer does not have an email address). This usage of undefined values is well-known in database modeling and querying with SQL [Dat90, EN94], in the Extended ER-Model [Gog94], and in the object specification language TROLL light [Her95].

2. An invalid value can signal an error in the evaluation of an expression. An example for an expression that is defined by a partial function is the division of integers. The result of a division by zero is undefined. The problems with partial functions can be eliminated by including an invalid value $\bot$ into the domains of types. For all operations we can then extend their interpretation to total functions.
The interpretation of operations is considered strict unless there is an explicit statement in the following. Hence, an invalid or null argument value causes an invalid operation result. This ensures the propagation of error conditions.

A.4.1.2 Operations

There are a number of predefined operations on basic types. The set $\Omega_B$ contains the signatures of these operations. An operation signature describes the name, the parameter types, and the result type of an operation.

Definition A.15 (Syntax Of Operations)

The syntax of an operation is defined by a signature $\omega : t_1 \times \cdots \times t_n \rightarrow t$. The signature contains the operation symbol $\omega$, a list of parameter types $t_1, \ldots, t_n \in T$, and a result type $t \in T$.

Table A.1 shows a schema defining most predefined operations over basic types. The left column contains partially parameterized signatures in $\Omega_B$. The right column specifies variations for the operation symbols or types in the left column.

The set of predefined operations includes the usual arithmetic operations $+, -, \_ \_ \_$, /, etc. for integers and real numbers, division (div) and modulo (mod) of integers, sign manipulation (-, abs), conversion of Real values to Integer values (floor, round), and comparison operations ($<$, $>$, $<$=, $>$=).

Operations for equality and inequality are presented later in sub clause A.2.2, since they apply to all types. Boolean values can be combined in different ways (and, or, xor, implies), and they can be negated (not). For strings the length of a string (size) can be determined, a string can be projected to a substring, and two strings can be concatenated (concat).

Finally, assuming a standard alphabet like ASCII or Unicode, case translations are possible with toUpperCase and toLowerCase.

Some operation symbols (such as + and -) are overloaded, that is there are signatures having the same operation symbol but different parameters (concerning number or type) and possibly different result types. Thus in general, the full argument list has to be considered in order to identify a signature unambiguously.

The operations in Table A.1 all have at least one parameter. There is another set of operations in $\Omega_B$ that do not have parameters. These operations are used to produce constant values of basic types. For example, the integer value 12 can be generated by the operation $12 : \rightarrow$ Integer. Similar operations exist for the other basic types. For each value, there is an operation with no parameters and an operation symbol that corresponds to the common notational representation of this value.

<table>
<thead>

<tr>
<td>$\preceq : t \rightarrow t$</td>
<td>$t \in {Integer, Real}$</td>
</tr>
</tbody>
</table>
A.4.1.3 Semantics of Operations

Definition A.16 (Semantics of Operations)

The semantics of an operation with signature \( \omega : t_1 \times \cdots \times t_n \rightarrow t \) is a total function \( I(\omega : t_1 \times \cdots \times t_n \rightarrow t) : I(t_1) \times \cdots \times I(t_n) \rightarrow I(t) \).

When we refer to an operation, we usually omit the specification of the parameter and result types and only use the operation symbol if the full signature can be derived from the context.

The next example shows the interpretation of the operation + for adding two integers. The operation has two arguments \( i_1, i_2 \in I(Integer) \). This example also demonstrates the strict evaluation semantics for undefined arguments.

\[
I(+) (i_1, i_2) = \begin{cases} 
  i_1 + i_2 & \text{if } i_1 \neq \bot \text{ and } i_2 \neq \bot, \\
  \bot & \text{otherwise}
\end{cases}
\]

We can define the semantics of the other operations in Table A.1 analogously. The usual semantics of the boolean operations and, or, xor, implies, and not, is extended for dealing with undefined argument values. Table A.2 shows the interpretation of boolean operations following the proposal in [CKM+99] based on three-valued logic. Since the semantics of the other basic operations for UnlimitedNatural, Integer, Real, and String values is rather obvious, we will not further elaborate on them here....

<table>
<thead>
<tr>
<th>abs: ( t \rightarrow t )</th>
<th>( t \in {\text{UnlimitedNatural, Integer, Real}} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>floor: ( t \rightarrow \text{Integer} )</td>
<td>( t \in {\text{UnlimitedNatural, Integer, Real}} )</td>
</tr>
<tr>
<td>round: ( t \rightarrow \text{Integer} )</td>
<td>( t \in {\text{UnlimitedNatural, Integer, Real}} )</td>
</tr>
<tr>
<td>( \omega : t_1 \times t_2 \rightarrow \text{Boolean} )</td>
<td>( \omega \in {&lt;, &gt;, \leq, \geq} )</td>
</tr>
<tr>
<td>( \omega : \text{Boolean} \times \text{Boolean} \rightarrow \text{Boolean} )</td>
<td>( \omega \in {\text{and, or, xor, implies}} )</td>
</tr>
<tr>
<td>not: ( \text{Boolean} \rightarrow \text{Boolean} )</td>
<td></td>
</tr>
<tr>
<td>size: ( \text{String} \rightarrow \text{Integer} )</td>
<td></td>
</tr>
<tr>
<td>concat: ( \text{String} \times \text{String} \rightarrow \text{String} )</td>
<td></td>
</tr>
<tr>
<td>toUpperCase: ( \text{String} \rightarrow \text{String} )</td>
<td></td>
</tr>
<tr>
<td>toLowerCase: ( \text{String} \rightarrow \text{String} )</td>
<td></td>
</tr>
<tr>
<td>substring: ( \text{String} \times \text{Integer} \times \text{Integer} \rightarrow \text{String} )</td>
<td></td>
</tr>
<tr>
<td>toString: ( t \rightarrow \text{String} )</td>
<td>( t \in {\text{UnlimitedNatural, Integer, Real, String, Boolean}} )</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>( b_1 )</td>
</tr>
<tr>
<td>false</td>
</tr>
<tr>
<td>false</td>
</tr>
</tbody>
</table>
A.4.2 Common Operations On All Types

At this point, we introduce some operations that are defined on all types (including those that are defined in subsequent sub clauses). The equality of values of the same type can be checked with the operation $=_t: t \times t \rightarrow \text{Boolean}$. Furthermore, the semantics of $=_t$ is defined to be strict. For two values $v_1, v_2 \in I(t)$, we have

$$I(=_t)(v_1, v_2) = \begin{cases} 
\text{true} & \text{if } v_1 = v_2, \text{ and } v_1 \neq \bot \text{ and } v_2 \neq \bot, \\
\bot & \text{if } v_1 = \bot \text{ or } v_2 = \bot, \\
\text{false} & \text{otherwise.}
\end{cases}$$
A test for inequality \( \neq : t \times t \rightarrow \text{Boolean} \) can be defined analogously. It is also useful to have an operation that allows one to check whether an arbitrary value is invalid or undefined. This can be done with the operations oclIsInvalid, \( : t \rightarrow \text{Boolean} \) and oclIsUndefined, \( t \rightarrow \text{Boolean} \) for any type \( t \in T \). The semantics of these operations is given for any \( v \in I(t) \) by:

\[
I(\text{oclIsInvalid})(v) = (v = \bot) \\
I(\text{oclIsUndefined})(v) = (v = \bot) \cup (v = \epsilon)
\]

### A.4.3 Enumeration Types

Enumeration types are user-defined types. An enumeration type is defined by specifying a name and a set of literals. An enumeration value is one of the literals used for its type definition. The syntax of enumeration types and their operations is defined by a signature \( \Sigma_E = (T_E, \Omega_E) \). \( T_E \) is the set of enumeration types and \( \Omega_E \) the set of signatures describing the operations on enumeration types.

**Definition A.17 (Syntax Of Enumeration Types)**

An enumeration type \( t \in T_E \) is associated with a finite non-empty set of enumeration literals by a function \( \text{literals}(t) = \{e_1, \ldots, e_n\} \).

An enumeration type is interpreted by the set of literals used for its declaration.

**Definition A.18 (Semantics Of Enumeration Types)**

The semantics of an enumeration type \( t \in T_E \) is a function \( I(t) = \text{literals}(t) \cup \{\epsilon, \bot\} \).

#### A.4.3.1 Operations

There is only a small number of operations defined on enumeration types: the test for equality or inequality of two enumeration values. The syntax and semantics of these general operations was defined in section A.4.2 and applies to enumeration types as well.

In addition, the operation allInstances, \( t : \rightarrow \text{Set}(t) \) is defined for each \( t \in T_E \) to return the set of all literals of the enumeration:

\[
\forall t \in T_E : I(\text{allInstances})(t) = \text{literals}(t)
\]

### A.4.4 Object Types

A central part of a UML model are classes that describe the structure of objects in a system. For each class, we define a corresponding object type describing the set of possible object instances. The syntax of object types and their operations is defined by a signature \( \Sigma_C = (T_C, \Omega_C) \). \( T_C \) is the set of object types, and \( \Omega_C \) is the set of signatures describing operations on object types.

**Definition A.19 (Syntax Of Object Types)**

Let \( M \) be a model with a set \( \text{CLASS} \) of class names. The set \( T_C \) of object types is defined such that for each class \( c \in \text{CLASS} \) there is a type \( t \in T_C \) having the same name as the class \( c \).

We define the following two functions for mapping a class to its type and vice versa.

\[
\text{typeOf} : \text{CLASS} \rightarrow T_C \\
\text{classOf} : T_C \rightarrow \text{CLASS}
\]
The interpretation of classes is used for defining the semantics of object types. The set of object identifiers $I_{CLASS}(c)$ was introduced in “Definition A.10 (Object Identifiers)” on page 200.

Definition A.20 (Semantics Of Object Types)

The semantics of an object type $t \in T_C$ with classOf($t$) = $c$ is defined as $I(t) = I_{CLASS}(c) \cup \{\epsilon, \perp\}$.

In summary, the domain of an object type is the set of object identifiers defined for the class and its children. The undefined null value that is only available with the type – not the class – allows us to work with values not referring to any existing object. This is useful, for example, when we have a navigation expression pointing to a class with multiplicity $0..1$. The result of the navigation expression is a value referring to the actual object only if a target object exists. Otherwise, the result is the invalid value.

A.4.4.1 Operations

There are four different kinds of operations that are specific to object types:

- **Predefined operations**: These are operations that are implicitly defined in OCL for all object types.
- **Attribute operations**: An attribute operation allows access to the attribute value of an object in a given system state.
- **Object operations**: A class may have operations that do not have side effects. These operations are marked in the UML model with the tag isQuery. In general, OCL expressions could be used to define object operations. The semantics of an object operation is therefore given by the semantics of the associated OCL expression.
- **Navigation operations**: An object may be connected to other objects via association links. A navigation expression allows one to follow these links and to retrieve connected objects.

A.4.4.2 Predefined Operations

For all classes $c \in CLASS$ with object type $t_c = typeOf(c)$ the operations

$$allInstances_{tc} : \rightarrow \text{Set}(tc)$$

are in $\Omega_C$. The semantics is defined as

$$I(allInstances_{tc} : \rightarrow \text{Set}(tc)) = \sigma_{CLASS}(c).$$

This interpretation of allInstances is safe in the sense that its result is always limited to a finite set. The extension of a class is always a finite set of objects.

A.4.4.3 Attribute Operations

Attribute operations are declared in a model specification by the set $ATT_c$ for each class $c$. The set contains signatures $a : t_c \rightarrow t$ with $a$ being the name of an attribute defined in the class $c$. The type of the attribute is $t$. All attribute operations in $ATT_c$ are elements of $\Omega_C$. The semantics of an attribute operation is a function mapping an object identifier to a value of the attribute domain. An attribute value depends on the current system state.

Definition A.21 (Semantics of Attribute Operations)

An attribute signature $a : t_c \rightarrow t$ in $\Omega_C$ is interpreted by an attribute value function $I_{ATT}(a : t_c \rightarrow t) : I(t_c) \rightarrow I(t)$ mapping objects of class $c$ to a value of type $t$. 

© ISO/IEC 2012 - All rights reserved
Note that attribute functions are defined for all possible objects. The attempt to access an attribute of a non-existent object results in the invalid value.

A.4.4.4 Object Operations

Object operations are declared in a model specification. For side-effect free operations the computation can often be described with an OCL expression. The semantics of a side-effect free object operation can then be given by the semantics of the OCL expression associated with the operation. We give a semantics for object operations in section A.5 when OCL expressions are introduced.

A.4.4.5 Navigation Operations

A fundamental concept of OCL is navigation along associations. Navigation operations start from an object of a source class and retrieve all connected objects of a target class. In general, every n-ary association induces a total of \( n \cdot (n - 1) \) directed navigation operations, because OCL navigation operations only consider two classes of an association at a time. For defining the set of navigation operations of a given class, we have to consider all associations the class is participating in. A corresponding function named participating was defined on page 4.

Definition A.22 (Syntax of Navigation Operations)

Let \( M \) be a model
\[
M = (\text{CLASS}, \text{ATT}_c, \text{OP}_c, \text{ASSOC}, \text{associates}, \text{roles}, \text{multiplicities}, \prec ).
\]

The set \( \Omega_{\text{nav}}(c) \) of navigation operations for a class \( c \in \text{CLASS} \) is defined such that for each association \( as \in \text{participating}(c) \) with \( \text{associates}(as) = \{c_1, \ldots, c_n\} \), \( \text{roles}(as) = \{r_1, \ldots, r_n\} \), and \( \text{multiplicities}(as) = \{M_1, \ldots, M_n\} \) the following signatures are in \( \Omega_{\text{nav}}(c) \).

For all \( i, j \in \{1, \ldots, n\} \) with \( i \neq j \), \( ci = c \), \( tc_i = \text{typeOf}(c_i) \), and \( tc_j = \text{typeOf}(c_j) \)
i. if \( n = 2 \) and \( M_j - \{0,1\} = \emptyset \) then \( r_j(\text{as}; r_i) : t_{ci} \rightarrow t_{cj} \in \Omega_{\text{nav}}(c) \),
ii. if \( n > 2 \) or \( M_j - \{0,1\} = \emptyset \) then \( r_j(\text{as}; r_i) : t_{ci} \rightarrow \text{Set } t_{cj} \in \Omega_{\text{nav}}(c) \).

All navigation operations are elements of \( \Omega_C \).

As discussed in Clause A.2, we use unique role names instead of class names for navigation operations in order to avoid ambiguities. The index of the navigation operation name specifies the association to be navigated along as well as the source role name of the navigation path. The result type of a navigation over binary associations is the type of the target class if the multiplicity of the target is given as \( 0 \ldots 1 \) or \( 1 \) (i). All other multiplicities allow an object of the source class to be linked with multiple objects of the target class. Therefore, we need a set type to represent the navigation result (ii). Non-binary associations always induce set-valued results since a multiplicity at the target end is interpreted in terms of all source objects. However, for a navigation operation, only a single source object is considered.

Navigation operations are interpreted by navigation functions. Such a function has the effect of first selecting all those links of an association where the source object occurs in the link component corresponding to the role of the source class. The resulting links are then projected onto those objects that correspond to the role of the target class.
Definition A.23 (Semantics of Navigation Operations)

The set of objects of class \(c_j\) linked to an object \(c_i\) via association \(as\) is defined as

\[ L(as)(c_i) = \{ c_j \mid (c_i, \ldots, c_j, \ldots, c_n) \in \sigma_{\text{CLASS}(c)} \} \]

The semantics of operations in \(\Omega_{\text{nav}}(c)\) is then defined as

\[ I(r_j(as,ri) : t_{ci} \rightarrow t_{cj})(c_i) = \begin{cases} (c_j) & \text{if } c_j \in L(as)(c_i), \\ \bot & \text{otherwise} \end{cases} \]

ii. \[ I(t_j(as,ri) : t_{ci} \rightarrow \text{Set}(t_{cj}))(c_i) = L(as)(c_i). \]

A.4.5 Collection and Tuple Types

We call a type that allows the aggregation of several values into a single value a complex type. OCL provides the complex types \(\text{Set}(t)\), \(\text{Sequence}(t)\), and \(\text{Bag}(t)\) for describing collections of values of type \(t\). There is also a supertype \(\text{Collection}(t)\) that describes common properties of these types. The OCL collection types are homogeneous in the sense that all elements of a collection must be of the same type \(t\). This restriction is slightly relaxed by the substitution rule for subtypes in OCL (see “Type Hierarchy” on page 216). The rule says that the actual elements of a collection must have a type that is a subtype of the declared element type. For example, a \(\text{Set}(\text{Person})\) may contain elements of type \(\text{Customer}\) or \(\text{Employee}\).

A.4.5.1 Syntax and Semantics

Since complex types are parameterized types, we define their syntax recursively by means of type expressions.

Definition A.24 (Type Expressions)

Let \(T\) be a set of types and \(l_1, \ldots, l_n \in N\) a set of disjoint names. The set of type expressions \(T_{\text{Expr}}(T)\) over \(T\) is defined as follows.

i. If \(t \in T\) then \(t \in T_{\text{Expr}}(T)\).
ii. If \(t \in T_{\text{Expr}}(T)\) then \(\text{Set}(t)\), \(\text{Sequence}(t)\), \(\text{Bag}(t) \in T_{\text{Expr}}(\omega T)\).
iii. If \(t \in T_{\text{Expr}}(\omega T)\) then \(\text{Collection}(t) \in T_{\text{Expr}}(\omega T)\).
iv. If \(t_1, \ldots, t_n \in T_{\text{Expr}}(\omega T)\) then \(\text{Tuple}(l_1 : t_1, \ldots, l_n : t_n) \in T_{\text{Expr}}(\omega T)\).

The definition says that every type \(t \in T\) can be used as an element type for constructing a set, sequence, bag, or collection type. The components of a tuple type are marked with labels \(l_1, \ldots, l_n\). Complex types may again be used as element types for constructing other complex types. The recursive definition allows unlimited nesting of type expressions.

For the definition of the semantics of type expressions we make the following conventions. Let \(F(S)\) denote the set of all finite subsets of a given set \(S\), \(S^*\) is the set of all finite sequences over \(S\), and \(B(S)\) is the set of all finite multisets (bags) over \(S\).
Definition A.25 (Semantics of Type Expressions)

Let \( ^T \) be a set of types where the domain of each \( t \in ^T \) is \( I(t) \). The semantics of type expressions \( T_{Expr}( ^T ) \) over \( ^T \) is defined for all \( t \in ^T \) as follows.

i. \( I(t) \) is defined as given.

ii. \( I(Set(t)) = F( I(t)) \cup \{ \bot \} \),
\[ I(Sequence(t)) = (I(t) \times) \cup \{ \bot \} \],
\[ I(Bag(t)) = B(I(t)) \cup \{ \bot \} \].

iii. \( I(Collection(t)) = I(Set(t)) \cup I(Sequence(t)) \cup I(Bag(t)) \).

iv. \( I(Tuple(l_1 : t_1, \ldots, l_n : t_n)) = I(t_1) \times \cdots \times I(t_n) \cup \{ \bot \} \).

In this definition, we observe that the interpretation of the type \( Collection(t) \) subsumes the semantics of the set, sequence, and bag type. In OCL, the collection type is described as a supertype of \( Set(t) \), \( Sequence(t) \), and \( Bag(t) \). This construction greatly simplifies the definition of operations having a similar semantics for each of the concrete collection types. Instead of explicitly repeating these operations for each collection type, they are defined once for \( Collection(t) \). Examples for operations that are “inherited” in this way are the size and includes operations that determine the number of elements in a collection or test for the presence of an element in a collection, respectively.

A.4.5.2 Operations

A.4.5.3 Constructors

The most obvious way to create a collection value is by explicitly enumerating its element values. We therefore define a set of generic operations that allow us to construct sets, sequences, and bags from an enumeration of element values. For example, the set \{1; 2; 5\} can be described in OCL by the expression \( Set\{1, 2, 5\} \), the list \{1; 2; 5\} by \( Sequence\{1, 2, 5\} \), and the bag \{2; 2; 7\} by \( Bag\{2, 2, 7\} \). A shorthand notation for collections containing integer intervals can be used by specifying lower and upper bounds of the interval. For example, the expression \( Sequence\{3..6\} \) denotes the sequence \{3; 4; 5; 6\}. This is only syntactic sugar because the same collection can be described by explicitly enumerating all values of the interval.

Operations for constructing collection values by enumerating their element values are called constructors. For types \( t \in T_{Expr}( ^T ) \) constructors in \( \Omega_{T_{Expr}( ^T )} \) are defined below. A parameter list \( t x \ldots x t \) denotes \( n (n \geq 0) \) parameters of the same type \( t \). We define constructors \( mkSet_t, mkSequence_t, \) and \( mkBag_t \) not only for any type \( t \) but also for any finite number \( n \) of parameters.

- \( mkSet_t : t x \ldots x t \rightarrow Set(t) \)
- \( mkSequence_t : t x \ldots x t \rightarrow Sequence(t) \)
- \( mkBag_t : t x \ldots x t \rightarrow Bag(t) \)

The semantics of constructors is defined for values \( v_1, \ldots, v_n \in I(t) \) by the following functions.

- \( I(mkSet_t)(v_1, \ldots, v_n) = \{ v_1, \ldots, v_n \} \)
- \( I(mkSequence_t)(v_1, \ldots, v_n) = \langle v_1, \ldots, v_n \rangle \)
- \( I(mkBag_t)(v_1, \ldots, v_n) = \{ \{ v_1, \ldots, v_n \} \} \)

A tuple constructor in OCL specifies values and labels for all components, for example, \( Tuple\{number:3, fruit:'apple', flag:true\} \). A constructor for a tuple with component types \( t_1, \ldots, t_n \) \( T_{Expr}( ^T ) \) \( (n \geq 1) \) is given in abstract syntax by the following operation.
The semantics of tuple constructors is defined for values \( v_i \in I(t_i) \) with \( i = 1, \ldots, n \) by the following function.

\[
I(\text{mkTuple})(l_1 : v_1, \ldots, l_n : v_n) = (v_1, \ldots, v_n)
\]

Note that constructors having element values as arguments are deliberately defined not to be strict. A collection value therefore may contain undefined \textit{null} values while still being well defined.

### A.4.5.4 Collection Operations

The definition of operations of collection types comprises the set of all predefined collection operations. Operations common to the types \textit{Set}(t), \textit{Sequence}(t), and \textit{Bag}(t) are defined for the supertype \textit{Collection}(t). Table A.3 shows the operation schema for these operations. For all \( t \in T_{T_{\text{Expr}}} \), the signatures resulting from instantiating the schema are included in \( \Omega_{T_{\text{Expr}}} \). The right column of the table illustrates the intended set-theoretic interpretation. For this purpose, \( C, C, C' \) are values of type \textit{Collection}(t), and \( v \) is a value of type \( t \).

#### Table A.6 - Operations for type \textit{Collection}(t)

<table>
<thead>
<tr>
<th>Signature</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>\textit{size}:</td>
<td>\textit{Collection}(t) \rightarrow \text{Integer}</td>
</tr>
<tr>
<td>\textit{count}:</td>
<td>\textit{Collection}(t) \times t \rightarrow \text{Integer}</td>
</tr>
<tr>
<td>\textit{includes}:</td>
<td>\textit{Collection}(t) \times t \rightarrow \text{Boolean}</td>
</tr>
<tr>
<td>\textit{excludes}:</td>
<td>\textit{Collection}(t) \times t \rightarrow \text{Boolean}</td>
</tr>
<tr>
<td>\textit{includesAll}:</td>
<td>\textit{Collection}(t) \times \textit{Collection}(t) \rightarrow \text{Boolean}</td>
</tr>
<tr>
<td>\textit{excludesAll}:</td>
<td>\textit{Collection}(t) \times \textit{Collection}(t) \rightarrow \text{Boolean}</td>
</tr>
<tr>
<td>\textit{isEmpty}</td>
<td>\textit{Collection}(t) \rightarrow \text{Boolean}</td>
</tr>
<tr>
<td>\textit{notEmpty}</td>
<td>\textit{Collection}(t) \rightarrow \text{Boolean}</td>
</tr>
<tr>
<td>\textit{sum}</td>
<td>\textit{Collection}(t) \rightarrow t</td>
</tr>
</tbody>
</table>

The operation schema in Table A.3 can be applied to sets (sequences, bags) by substituting \textit{Set}(t) (\textit{Sequence}(t), \textit{Bag}(t)) for all occurrences of type \textit{Collection}(t). A semantics for the operations in Table A.3 can be easily defined for each of the concrete collection types \textit{Set}(t), \textit{Sequence}(t), and \textit{Bag}(t). The semantics for the operations of \textit{Collection}(t) can then be reduced to one of the three cases of the concrete types because every collection type is either a set, a sequence, or a bag. Consider, for example, the operation \textit{count} : \textit{Set}(t) \times t \rightarrow \text{Integer} that counts the number of occurrences of an element \( v \) in a set \( s \). The semantics of \textit{count} is:

\[
I(\text{count}) : \textit{Set}(t) \times t \rightarrow \text{Integer}(s,v) = \begin{cases} 
1 & \text{if } v \in s, \\
2 & \text{if } v \notin s \\
\bot & \text{if } s = \bot.
\end{cases}
\]

Note that \textit{count} is not strict. A set may contain the undefined \textit{null} value so that the result of \textit{count} is 1 if the \textit{null} value is passed as the second argument, for example, \textit{count}\{\{\varepsilon\}\}, \varepsilon = 1 and \textit{count}\{\{1\}\}, \varepsilon = 0.
For bags (and very similar for sequences), the meaning of count is
\[ I(\text{count} : \text{Bag}(t) \times t \rightarrow \text{Integer})(\{v_1, \ldots, v_n\}, v) = \begin{cases} 0 & \text{if } n = 0, \\ I(\text{count})(\{v_2, \ldots, v_n\}, v) & \text{if } n > 0 \text{ and } v_1 \neq v, \\ I(\text{count})(\{v_2, \ldots, v_n\}, v) + 1 & \text{if } n > 0 \text{ and } v_1 = v. \end{cases} \]

As explained before, the semantics of count for values of type \(\text{Collection}(t)\) can now be defined in terms of the semantics of count for sets, sequences, and bags.
\[ I(\text{count} : \text{Collection}(t) \times t \rightarrow \text{Integer})(c,v) = \begin{cases} I(\text{count} : \text{Set}(t) \times t \rightarrow \text{Integer})(c,v) & \text{if } c \in I(\text{Set}(t)), \\ I(\text{count} : \text{Sequence}(t) \times t \rightarrow \text{Integer})(c,v) & \text{if } c \in I(\text{Sequence}(t)), \\ I(\text{count} : \text{Bag}(t) \times t \rightarrow \text{Integer})(c,v) & \text{if } c \in I(\text{Bag}(t)), \\ \bot & \text{otherwise.} \end{cases} \]

### A.4.5.5 Set Operations

Operations on sets include the operations listed in Table A.6. These are inherited from \(\text{Collection}(t)\). Operations that are specific to sets are shown in Table A.7 where \(S, S_1, S_2\) are values of type \(\text{Set}(t)\), \(B\) is a value of type \(\text{Bag}(t)\) and \(v\) is a value of type \(t\).

<table>
<thead>
<tr>
<th>Signature</th>
<th>Semantics</th>
</tr>
</thead>
<tbody>
<tr>
<td>union: (\text{Set}(t) \times \text{Set}(t) \rightarrow \text{Set}(t))</td>
<td>(S_1 \cup S_2)</td>
</tr>
<tr>
<td>union: (\text{Set}(t) \times \text{Bag}(t) \rightarrow \text{Bag}(t))</td>
<td>(S \cup B)</td>
</tr>
<tr>
<td>intersection: (\text{Set}(t) \times \text{Set}(t) \rightarrow \text{Set}(t))</td>
<td>(S_1 \cap S_2)</td>
</tr>
<tr>
<td>intersection: (\text{Set}(t) \times \text{Bag}(t) \rightarrow \text{Set}(t))</td>
<td>(S \cap B)</td>
</tr>
<tr>
<td>-: (\text{Set}(t) \times \text{Set}(t) \rightarrow \text{Set}(t))</td>
<td>(S_1 \setminus S_2)</td>
</tr>
<tr>
<td>symmetricDifference: (\text{Set}(t) \times \text{Set}(t) \rightarrow \text{Set}(t))</td>
<td>((S_1 \cup S_2) - (S_1 \cap S_2))</td>
</tr>
<tr>
<td>including: (\text{Set}(t) \times t \rightarrow \text{Set}(t))</td>
<td>(S \cup {v})</td>
</tr>
<tr>
<td>excluding: (\text{Set}(t) \times t \rightarrow \text{Set}(t))</td>
<td>(S - {v})</td>
</tr>
<tr>
<td>asSequence: (\text{Set}(t) \times t \rightarrow \text{Sequence}(t))</td>
<td></td>
</tr>
<tr>
<td>asBag: (\text{Set}(t) \rightarrow \text{Bag}(t))</td>
<td></td>
</tr>
</tbody>
</table>

Note that the semantics of the operation as Sequence is nondeterministic. Any sequence containing only the elements of the source set (in arbitrary order) satisfies the operation specification in OCL.
### A.4.5.6 Bag Operations

Operations for bags are shown in Table A.8, the operation asSequence is nondeterministic also for bags.

<table>
<thead>
<tr>
<th>Table A.8- Operations for type Bag(t)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Signature</strong></td>
</tr>
<tr>
<td>union: Bag(t) x Bag(t) ↦ Bag(t)</td>
</tr>
<tr>
<td>union: Bag(t) x Set(t) ↦ Bag(t)</td>
</tr>
<tr>
<td>intersection: Bag(t) x Bag(t) ↦ Bag(t)</td>
</tr>
<tr>
<td>intersection: Bag(t) x Set(t) ↦ Set(t)</td>
</tr>
<tr>
<td>including: Bag(t) x t ↦ Bag(t)</td>
</tr>
<tr>
<td>excluding: Bag(t) x t ↦ Bag(t)</td>
</tr>
<tr>
<td>asSequence: Bag(t) x t ↦ Sequence(t)</td>
</tr>
<tr>
<td>asSet: Bag(t) ↦ Set(t)</td>
</tr>
</tbody>
</table>

### A.4.5.7 Sequence Operations

Sequence operations are displayed in Table A.9. The intended semantics again is shown in the right column of the table. S, S₁, S₂ are sequences occurring as argument values, v is a value of type t, and i, j are arguments of type Integer. The length of sequence S is n. The operator o denotes the concatenation of lists, πₙ(S) projects the iₙth element of a sequence S, and πₙ,j(S) results in a subsequence of S starting with the iₙth element up to and including the jₙth element. The result is ⊥ if an index is out of range. S - {v} produces a sequence equal to S but with all elements equal to v removed. Note that the operations append and including are also defined identically in the OCL standard.

<table>
<thead>
<tr>
<th>Table A.9- Operations for type Sequence(t)</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Signature</strong></td>
</tr>
<tr>
<td>union: Sequence(t) x Sequence(t) ↦ Sequence(t)</td>
</tr>
<tr>
<td>append: Sequence(t) x t ↦ Sequence(t)</td>
</tr>
<tr>
<td>prepend: Sequence(t) x t ↦ Sequence(t)</td>
</tr>
<tr>
<td>subSequence: Sequence(t) x Integer x Integer ↦ Sequence(t)</td>
</tr>
<tr>
<td>at: Sequence(t) x Integer ↦ t</td>
</tr>
<tr>
<td>first: Sequence(t) ↦ t</td>
</tr>
<tr>
<td>last: Sequence(t) ↦ t</td>
</tr>
<tr>
<td>including: Sequence(t) x t ↦ Sequence(t)</td>
</tr>
<tr>
<td>excluding: Sequence(t) x t ↦ Sequence(t)</td>
</tr>
<tr>
<td>asSet: Sequence(t) ↦ Set(t)</td>
</tr>
<tr>
<td>asBag: Sequence(t) ↦ Bag(t)</td>
</tr>
</tbody>
</table>

### A.4.5.8 Flattening Of Collections

Type expressions as introduced in Definition A.24 allow arbitrarily deep nested collection types. We pursue the following approach for giving a precise meaning to collection flattening. First, we keep nested collection types because they not only make the type system more orthogonal, but they are also necessary for describing the input of the flattening process.
Second, we define flattening by means of an explicit function making the effect of the flattening process clear. There may be a shorthand notation omitting the flatten operation in concrete syntax that would expand in abstract syntax to an expression with an explicit flattening function.

Flattening in OCL does apply to all collection types. We have to consider all possible combinations first. Table A.10 shows all possibilities for combining Set, Bag, and Sequence into a nested collection type. For each of the different cases, the collection type resulting from flattening is shown in the right column. Note that the element type \( t \) can be any type. In particular, if \( t \) is also a collection type the indicated rules for flattening can be applied recursively until the element type of the result is a non-collection type.

### Table A.10 - Flattening of nested collections

<table>
<thead>
<tr>
<th>Nested collection type</th>
<th>Type after flattening</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set(Sequence(( t )))</td>
<td>Set(( t ))</td>
</tr>
<tr>
<td>Set(Set(( t )))</td>
<td>Set(( t ))</td>
</tr>
<tr>
<td>Set(Bag(( t )))</td>
<td>Set(( t ))</td>
</tr>
<tr>
<td>Bag(Sequence(( t )))</td>
<td>Bag(( t ))</td>
</tr>
<tr>
<td>Bag(Set(( t )))</td>
<td>Bag(( t ))</td>
</tr>
<tr>
<td>Bag(Bag(( t )))</td>
<td>Bag(( t ))</td>
</tr>
<tr>
<td>Sequence(Sequence(( t )))</td>
<td>Sequence(( t ))</td>
</tr>
<tr>
<td>Sequence(Set(( t )))</td>
<td>Sequence(( t ))</td>
</tr>
<tr>
<td>Sequence(Bag(( t )))</td>
<td>Sequence(( t ))</td>
</tr>
</tbody>
</table>

A signature schema for a flatten operation that removes one level of nesting can be defined as

\[
\text{flatten} : C_1(C_2(\( t \))) \rightarrow C_1(\( t \))
\]

where \( C_1 \) and \( C_2 \) denote any collection type name Set, Sequence, or Bag. The meaning of the flatten operations can be defined by the following generic iterate expression. The semantics of OCL iterate expressions is defined in section A.5.1.2.

\[
<\text{collection-of-type-}C_1(C_2(\( t \)))>\rightarrow\text{iterate}(e_1 : C_2(\( t \));
  \text{acc}1 : C_1(\( t \)) = C_1 \{\} |
  e_1\rightarrow\text{iterate}(v : \( t \);
    \text{acc}2 : C_1(\( t \)) = \text{acc}1 |
    \text{acc}2\rightarrow\text{including}(v)))
\]

The following example shows how this expression schema is instantiated for a bag of sets of integers, that is, \( C_1 = \text{Bag} \), \( C_2 = \text{Set} \), and \( \( t \) = \text{Integer} \). The result of flattening the value Bag \{Set \{3,2\}, Set \{1,2,4\}\} is Bag \{1,2,2,3,4\}.

\[
\text{Bag}\{\text{Set}\{3,2\}\!,\text{Set}\{1,2,4\}\} \rightarrow\text{iterate}(e_1 : \text{Set}(\text{Integer});
  \text{acc}1 : \text{Bag}(\text{Integer}) = \text{Bag} \{\} |
  e_1\rightarrow\text{iterate}(v : \text{Integer};
    \text{acc}2 : \text{Bag}(\text{Integer}) = \text{acc}1 |
    \text{acc}2\rightarrow\text{including}(v))
\]

It is important to note that flattening sequences of sets and bags (see the last two rows in Table A.10) is potentially nondeterministic. For these two cases, the flatten operation would have to map each element of the (multi-) set to a distinct position in the resulting sequence, thus imposing an order on the elements that did not exist in the first place.
Since there are types (e.g., object types) that do not define an order on their domain elements, there is no obvious mapping for these types. Fortunately, these problematic cases do not occur in standard navigation expressions. Furthermore, these kinds of collections can be flattened if the criteria for ordering the elements is explicitly specified.

### A.4.5.9 Tuple Operations

An essential operation for tuple types is the projection of a tuple value onto one of its components. An element of a tuple with labeled components can be accessed by specifying its label.

- \( \text{element}_{li} : \text{Tuple}(l_1 : t_1, \ldots, l_i : t_i, \ldots, l_n : t_n) \rightarrow t_i \)
- \( I(\text{element}_{li} : \text{Tuple}(l_1 : t_1, \ldots, l_i : t_i, \ldots, l_n : t_n)) \rightarrow t_i(v_1, \ldots, v_i, \ldots, v_n) = v_i \)

### A.4.6 Special Types

Special types in OCL that do not fit into the categories discussed so far are \( \text{OclAny} \), \( \text{OclState} \), and \( \text{OclVoid} \).

- **OclAny**: is the supertype of all other types except for the collection types. The exception has been introduced in UML because it considerably simplifies the type system [CKM+99]. A simple set inclusion semantics for subtype relationships as described in the next sub section would not be possible due to cyclic domain definitions if \( \text{OclAny} \) were the supertype of \( \text{Set(OclAny)} \).
- **OclState**: is a type very similar to an enumeration type. It is only used in the operation \( \text{oclInState} \) for referring to state names in a state machine. There are no operations defined on this type. \( \text{OclState} \) is therefore not treated specially.
- **OclVoid**: is the subtype of types other than \( \text{OclVoid} \) and \( \text{OclInvalid} \). The only value of this type is \( \text{null} \), the undefined value. Notice that there is no problem with cyclic domain definitions as \( \varepsilon \) is an instance of every type other than \( \text{OclInvalid} \).
- **OclInvalid**: is the subtype of all other types. The only value of this type is \( \text{invalid} \), the invalid value. Notice that there is no problem with cyclic domain definitions as \( \bot \) is an instance of every type.

**Definition A.26 (Special Types)**

The set of special types is \( T_S = \{ \text{OclAny}, \text{OclVoid}, \text{OclInvalid} \} \).

Let \( \hat{T} \) be the set of basic, enumeration, and object types \( T = T_B \cup T_E \cup T_C \). The domain of \( \text{OclAny} \) is given as

\[
I(\text{OclAny}) = \left( \bigcup_{t \in \hat{T}} I(t) \right) \cup \{ \varepsilon, \bot \}.
\]

The domain of \( \text{OclVoid} \) is \( I(\text{OclVoid}) = \{ \varepsilon, \bot \} \).

The domain of \( \text{OclInvalid} \) is \( I(\text{OclInvalid}) = \{ \bot \} \).

Operations on \( \text{OclAny} \) include equality (=) and inequality (<> ) that already have been defined for all types in sub clause A.4.2. The operations \( \text{oclIsKindOf}, \text{oclIsTypeOf}, \text{oclAsType} \) expect a type as argument. We define them as part of the OCL expression syntax in the next section. The operation \( \text{oclIsNew} \) is only allowed in postconditions and will be discussed in sub clause A.5.2.

For \( \text{OclVoid} \) and \( \text{OclInvalid} \), the constant operation \( \text{oclIsUndefined} : \rightarrow \text{Boolean} \) results in the true value, and for \( \text{OclInvalid} \), the constant operation \( \text{oclIsInvalid} : \rightarrow \text{Boolean} \) results in the true value. The semantics is given by \( I(\text{OclVoid}) = \{ \varepsilon, \bot \} \) and \( I(\text{OclInvalid}) = \bot \).
A.4.7 Type Hierarchy

The type system of OCL supports inclusion polymorphism by introducing the concept of a type hierarchy. The type hierarchy is used to define the notion of type conformance. Type conformance is a relationship between two types, expressed by the conformsTo () operation from the abstract syntax metamodel. A valid OCL expression is an expression in which all the types conform. The consequence of type conformance can be loosely stated as: a value of a conforming type B may be used wherever a value of type A is required.

The type hierarchy reflects the subtype/supertype relationship between types. The following relationships are defined in OCL.

1. UnlimitedNatural is a subtype of Integer.
2. Integer is a subtype of Real.
3. All types, except for the collection and tuple types, are subtypes of OclAny.
4. Set(t), Sequence(t), and Bag(t) are subtypes of Collection(t).
5. OclVoid is a subtype of all types other than OclVoid and OclInvalid.
6. OclInvalid is a subtype of all other types.
7. The hierarchy of types introduced by UML model elements mirrors the generalization hierarchy in the UML model.

Type conformance is a relation that is identical to the subtype relation introduced by the type hierarchy. The relation is reflexive and transitive.

Definition A.27 (Type Hierarchy)

Let T be a set of types and TC a set of object types with TC _ T. The relation _ is a partial order on T and is called the type hierarchy over T. The type hierarchy is defined for all t; t0; t00 2 T and all tc; t0 c 2 TC; n; m 2 N as follows:

i. _ is (a) reflexive, (b) transitive, and (c) antisymmetric:
   (a) t _ t
   (b) t'' _ t' ^ t' _ t ⇒ t'' _ t
   (c) t'' _ t' ^ t _ t ⇒ t = t'

ii. UnlimitedNatural _ Integer.
iii. Integer _ Real.
iv. t _ OclAny for all t 2 (TB U TE U TC).
v. OclVoid _ t.
vi. OclInvalid _ OclVoid.
vii. Set(t) _ Collection(t).
     Sequence(t) _ Collection(t), and
     Bag(t) _ Collection(t).
viii. If t' _ t then Set(t') _ Set(t), Sequence(t') _ Sequence(t), Bag(t') _ Bag(t), and
     Collection(t') _ Collection(t).
ix. If t'i _ t for i = 1, . . . , n and n _ m then
     Tuple(l1 : t'1, . . . , ln : t'n, . . . , l_m : t'm) _ Tuple(l1 : t1, . . . , ln : tn).
x. If classOf(t'c) _ classOf(tc) then t'c _ tc .

If a type t' is a subtype of another type t (i.e., t' _ t), we say that t' conforms to t. Type conformance is associated with the principle of substitutability. A value of type t' may be used wherever a value of type t is expected. This rule is defined more formally in A.5.1, which defines the syntax and semantics of expressions.
The principle of substitutability and the interpretation of types as sets suggest that the type hierarchy should be defined as a subset relation on the type domains. Hence, for a type \( t' \) being a subtype of \( t \), we postulate that the interpretation of \( t' \) is a subset of the interpretation of \( t \). It follows that every operation \( \omega \) accepting values of type \( t \) has the same semantics for values of type \( t' \), since \( I(\omega) \) is already well-defined for values in \( I(t') \):

If \( t' \leq t \) then \( I(t') \subseteq I(t) \) for all types \( t', t \in T \).

### A.4.8 Data Signature

We now have available all elements necessary to define the final data signature for OCL expressions. The signature provides the basic set of syntactic elements for building expressions. It defines the syntax and semantics of types, the type hierarchy, and the set of operations defined on types.

**Definition A.28 (Data Signature)**

Let \( \wedge T \) be the set of non-collection types: \( \wedge T = T_B \cup T_E \cup T_C \cup T_S \). The syntax of a data signature over an object model \( M \) is a structure \( \Sigma_M = (T_M, \preceq, \Omega_M) \) where

i. \( T_M = T_{\text{Expr}}(\wedge T) \),

ii. \( \preceq \) is a type hierarchy over \( T_M \),

iii. \( \Omega_M = \Omega_{T_{\text{Expr}}(\wedge T)} \cup \Omega_B \cup \Omega_E \cup \Omega_C \cup \Omega_S \).

The semantics of \( \Sigma_M \) is a structure \( I(\Sigma_M) = (I(T_M), I(\preceq), I(\Omega_M)) \) where

i. \( I(T_M) \) assigns each \( t \in T_M \) an interpretation \( I(t) \),

ii. \( I(\preceq) \) implies for all types \( t', t \in T_M \) that \( I(t') \subseteq I(t) \) if \( t' \leq t \).

iii. \( I(\Omega_M) \) assigns each operation \( \omega : t_1 \times \ldots \times t_n \rightarrow t \in \Omega_M \) a total function

\[
I(\omega) : I(t_1) \times \ldots \times I(t_n) \rightarrow I(t).
\]

## A.5 OCL Expressions and Constraints

The core of OCL is given by an expression language. Expressions can be used in various contexts, for example, to define constraints such as class invariants and pre-/postconditions on operations. In this sub clause, we formally define the syntax and semantics of OCL expressions, and give precise meaning to notions like context, invariant, and pre-/postconditions.

Sub clause A.5.1 defines the abstract syntax and semantics of OCL expressions and shows how other OCL constructs can be derived from this language core. The context of expressions and other important concepts such as invariants, queries, and shorthand notations are discussed. Sub clause A.5.2 defines the meaning of operation specifications with pre- and postconditions.

### A.5.1 Expressions

In this sub clause, we define the syntax and semantics of expressions. The definition of expressions is based upon the data signature we developed in the previous sub clause. A data signature \( \Sigma_M = (T_M, \preceq, \Omega_M) \) provides a set of types \( T_M \), a relation \( \leq \) on types reflecting the type hierarchy, and a set of operations \( \Omega_M \). The signature contains the initial set of syntactic elements upon which we build the expression syntax.
A.5.1.1 Syntax of Expressions

We define the syntax of expressions inductively so that more complex expressions are recursively built from simple structures. For each expression the set of free occurrences of variables is also defined. Also, each sub clause in the definition corresponds to a subclass of OCLExpression in the abstract syntax. The mapping is indicated.

Definition A.29 (Syntax of Expressions)

Let \( \Sigma_M = (T_M \leq \Omega_M) \) be a data signature over an object model \( M \). Let \( \text{Var} = \{ \text{Var}_t \}_{t \in T_M} \) be a family of variable sets where each variable set is indexed by a type \( t \). The syntax of expressions over the signature \( \Sigma_M \) is given by a set \( \text{Expr} = \{ \text{Expr}\} t \in T_M \) and a function \( \text{free} : \text{Expr} \rightarrow F(\text{Var}) \) that are defined as follows.

i. If \( v \in \text{Var}_t \), then \( v \in \text{Expr}_t \) and \( \text{free}(v) := \{ v \} \). This maps into the \text{VariableExp} class in the abstract syntax.

ii. If \( v \in \text{Var}_{t_1}, e_1 \in \text{Expr}_{t_1}, e_2 \in \text{Expr}_{t_2} \) then \( \text{let} v = e_1 \ in \ e_2 \in \text{Expr}_{t_2} \) and \( \text{free} \ (\text{let} v = e_1 \ in \ e_2) := \text{free}(e_2) \setminus \{ v \} \). This maps into \text{LetExpression} in the abstract syntax. \( v = e_1 \) is the \text{VariableDeclaration} referred through the \text{variable} association; \( e_2 \) is the \text{OclExpression} referred through association end \( \text{in} \). \( e_1 \) is the \text{OclExpression} referred from the \text{VariableDeclaration} through the \text{initExpression} association.

iii. (a) If \( t \in T_M \) and \( \omega : t \rightarrow t \in \Omega_M \), then \( \omega \in \text{Expr}_t \) and \( \text{free}(\omega) := \emptyset \) and \( \text{free}(\text{undefined}) := \emptyset \). This maps into the \text{ConstantExp} class and its subclasses from the abstract syntax.

(b) If \( \omega : t_1 \times \ldots \times t_n \rightarrow t \in \Omega_M \) and \( e_i \in \text{Expr}_{t_i} \) for all \( i = 1, \ldots, n \) then \( \omega \ (e_1, \ldots, e_n) \in \text{Expr}_t \) and \( \text{free}(\omega (e_1, \ldots, e_n)) := \text{free}(e_1) \cup \ldots \cup \text{free}(e_n) \). This maps into \text{ModelPropertyCallExp} and its subclasses, with \( e_1 \) representing the \text{source} and \( e_2 \) to \text{en} the \text{arguments}.

iv. If \( e_1 \in \text{Expr}_{\text{Boolean}} \) and \( e_2, e_3 \in \text{Expr}_t \) then \( \text{if} e_1 \text{ then } e_2 \text{ else } e_3 \text{ endif } \in \text{Expr}_t \) and \( \text{free}(\text{if} (e_1 \text{ then } e_2 \text{ else } e_3 \text{ endif}) := \text{free}(e_1) \cup \text{free}(e_2) \cup \text{free}(e_3) \). This corresponds to the \text{IfExpression} in the abstract syntax. \( e_1 \) is the \text{OclExpression} referred through \text{condition}, \( e_2 \) corresponds to the \text{thenExpression} association, and \( e_3 \) maps into the \text{OclExpression} \text{elseExpression}.

v. If \( \ e \in \text{Expr}_t \) and \( t' \leq t \) or \( t \leq t' \) then \( (e \text{ asType } t') \in \text{Expr}_{t'} \). \( (e \text{ isTypeOf } t') \in \text{Expr}_{\text{Boolean}} \). \( (e \text{ isKindOf } t') \in \text{Expr}_{t'} \) and \( \text{free}(e \text{ asType } t') := \text{free}(e), \text{free}(e \text{ isTypeOf } t') := \text{free}(e), \text{free}(e \text{ isKindOf } t') := \text{free}(e) \). This maps into some special instances of \text{OclOperationWithReturnType}.

vi. If \( e_1 \in \text{Expr}_{\text{Collection}(l)} \), \( v_1 \in \text{Var}_{t_1}, v_2 \in \text{Var}_{t_2}, \) and \( e_2, e_3 \in \text{Expr}_{t_2} \) then \( e_1 \rightarrow \text{iterate}(v_1; v_2 = e_2 \mid e_3) \in \text{Expr}_t \) and \( \text{free}(e_1 \rightarrow \text{iterate}(v_1; v_2 = e_2 \mid e_3)) := (\text{free}(e_1) \cup \text{free}(e_2) \cup \text{free}(e_3)) \setminus \{ v_1, v_2 \} \). This is a representation of the \text{IterableExp}. \( e_1 \) is the \text{source}, \( v_2 = e_2 \) is the \text{VariableDeclaration} which is referred to through the \text{result} association in the abstract syntax. \( v_1 \) corresponds to the \text{iterator} \text{VariableDeclaration}. Finally, \( e_3 \) is the \text{OclExpression} \text{body}. Instances of \text{IteratorExp} are defined in the OCL Standard Library.

An expression of type \( t' \) is also an expression of a more general type \( t \). For all \( t' \leq t \), if \( e \in \text{Expr}_{t'} \) then \( e \in \text{Expr}_t \).

A variable expression (i) refers to the value of a variable. Variables (including the special variable \text{self}) may be introduced by the context of an expression, as part of an iterate expression, and by a let expression. Let expressions (ii) do not add to the expressiveness of OCL but help to avoid repetitions of common sub-expressions. Constant expressions (iiiA) refer to a value from the domain of a type. Operation expressions (iiib) apply an operation from \( \Omega_M \). The set of operations includes:

- predefined data operations: +, -, *, <, >, size, max
- attribute operations: \text{self.age}, \text{e.salary}
• side-effect free operations defined by a class:
  b.rentalsForDay(...)

• navigation by role names: self.employee

As demonstrated by the examples, an operation expression may also be written in OCL path syntax as $e_1.o(e_2, \ldots, e_n)$. This notational style is common in many object-oriented languages. It emphasizes the role of the first argument as the “receiver” of a “message.” If $e_1$ denotes a collection value, an arrow symbol is used in OCL instead of the period: $e_1 \to o(e_2, \ldots, e_n)$. Collections may be bags, sets, or lists.

An if-expression (iv) provides an alternative selection of two expressions depending on the result of a condition given by a boolean expression.

An asType expression (v) can be used in cases where static type information is insufficient. It corresponds to the oclAsType operation in OCL and can be understood as a cast of a source expression to an equivalent expression of a (usually) more specific target type. The target type must be related to the source type, that is, one must be a subtype of the other. The isTypeOf and isKindOf expressions correspond to the oclIsTypeOf and oclIsKindOf operations, respectively. An expression ($e$ isTypeOf $t'$) can be used to test whether the type of the value resulting from the expression $e$ has the type $t'$ given as argument. An isKindOf expression ($e$ isKindOf $t'$) is not as strict in that it is sufficient for the expression to become true if $t'$ is a supertype of the type of the value of $e$. Note that in previous OCL versions these type casts and tests were defined as operations with parameters of type OclType. Here, we technically define them as first class expressions, which has the benefit that we do not need the metatype OclType. Thus the type system is kept simple while preserving compatibility with standard OCL syntax.

An iterate expression (vi) is a general loop construct that evaluates an argument expression $e_3$ repeatedly for all elements of a collection that is given by a source expression $e_1$. Each element of the collection is bound in turn to the variable $v_1$ for each evaluation of the argument expression. The argument expression $e_3$ may contain the variable $v_1$ to refer to the current element of the collection. The result variable $v_2$ is initialized with the expression $e_2$. After each evaluation of the argument expression $e_3$, the result is bound to the variable $v_2$. The final value of $v_2$ is the result of the whole iterate expression.

The iterate construct is probably the most important kind of expression in OCL. Many other OCL constructs (such as select, reject, collect, exists, forAll, and isUnique) can be equivalently defined in terms of an iterate expression (see A.5.1.3).

Following the principle of substitutability, the syntax of expressions is defined such that wherever an expression $e \in Expr_t$ is expected as part of another expression, an expression with a more special type $t', (t' \leq t)$ may be used. In particular, operation arguments and variable assignments in let and iterate expressions may be given by expressions of more special types.

A.5.1.2 Semantics of Expressions

The semantics of expressions is made precise in the following definition. A context for evaluation is given by an environment $\pi = (\sigma, \beta)$ consisting of a system state $\sigma$ and a variable assignment $\beta : Var \rightarrow I(t)$. A system state $\sigma$ provides access to the set of currently existing objects, their attribute values, and association links between objects. A variable assignment $\beta$ maps variable names to values.

Definition A.30 (Semantics of Expressions)

Let $Env$ be the set of environments $\pi = (\sigma, \beta)$. The semantics of an expression $e \in Expr_t$ is a function $I[[ e ]] : Env \rightarrow I(t)$ that is defined as follows.

i. $I[[v]](\sigma) = \beta(v)$. 
ii. \( \mathcal{I}([\text{let } v = e_1 \text{ in } e_2])(r) = \mathcal{I}([e_2])(\sigma, \beta \{ v / \mathcal{I}[e_1](r) \}) \).

iii. \( \mathcal{I}([\text{undefined}]) (r) = \perp \) and \( \mathcal{I}([w])(r) = \mathcal{I}(w) \)

iv. \( \mathcal{I}([w(e_1, \ldots, e_n)])(r) = \mathcal{I}(w) (\pi) (\mathcal{I}[e_1](r), \ldots, \mathcal{I}[e_n](r)) \).

v. \( \mathcal{I}([\text{if } e_1 \text{ then } e_2 \text{ else } e_3 \text{ endif}]) (r) = \begin{cases} \mathcal{I}[e_2] (r) & \text{if } \mathcal{I}[e_1](r) = \text{true}, \\ \mathcal{I}[e_3] (r) & \text{if } \mathcal{I}[e_1](r) = \text{false}, \\ \perp & \text{otherwise}. \end{cases} \)

vi. \( \mathcal{I}([e \text{ asType } t']) (r) = \begin{cases} I[[e]] (r) & \text{if } I[[e]](r) \in I(t'), \\ \perp & \text{otherwise}. \end{cases} \)

\( \mathcal{I}([e \text{ isType } t']) (r) = \begin{cases} \text{true} & \text{if } I[[e]](r) \in I(t') - U_{t'} I(t''), \\ \text{false} & \text{otherwise}. \end{cases} \)

\( \mathcal{I}([e \text{ asKindOf } t']) (r) = \begin{cases} \text{true} & \text{if } I[[e]](r) \in I(t'), \\ \text{false} & \text{otherwise}. \end{cases} \)

vii. \( \mathcal{I}([e_1 \rightarrow \text{iterate}(v_1; v_2 = e_2 \mid e_3)]) (r) = \mathcal{I}([e_1 \rightarrow \text{iterate}' (v_1 \mid e_2)]) (r') \) where \( r' = (\sigma, \beta') \) and \( r'' = (\sigma, \beta'') \) are environments with modified variable assignments

\[ \beta' := \beta \{ v_2 / \mathcal{I}[e_2] (r) \} \quad \beta'' := \beta' \{ v_2 / \mathcal{I}[e_3] (\sigma, \beta' \{ v_1 / x_1 \}) \} \]

and iterate' is defined as:

(a) If \( e_1 \in \text{Expr\_Sequence(t1)} \) then

\[ \mathcal{I}([e_1 \rightarrow \text{iterate}' v_1 \mid e_3]) (r') = \begin{cases} I[[v_2]] (r') & \text{if } I[[e_1]](r') = \text{()}, \\ I[[\text{mkSequence}_{t1} (x_2, \ldots, x_n) \rightarrow \text{iterate}'(v_1 \mid e_3)]]] (r'') & \text{if } I[[e_1]](r') = \langle x_1, \ldots, x_n \rangle. \end{cases} \]
(b) If $e_1 \in \text{Expr Set}(t_1)$ then

$$
\text{I}[[e_1 \rightarrow \text{iterate}' v_1 | e_3]](r') =
\begin{cases}
I[[v_2]](r') & \text{if } I[[e_1]](r') = \emptyset, \\
I[[\text{mkSet}_{t_1}(x_2, \ldots, x_n) \rightarrow \text{iterate}'(v_1 | e_3)]](r'') & \text{if } I[[e_1]](r') = \{x_1, \ldots, x_n\}.
\end{cases}
$$

(c) If $e_1 \in \text{Expr Bag}(t_1)$ then

$$
\text{I}[[e_1 \rightarrow \text{iterate}' v_1 | e_3]](r') =
\begin{cases}
I[[v_2]](r') & \text{if } I[[e_1]](r') = \emptyset, \\
I[[\text{mkBag}_{t_1}(x_2, \ldots, x_n) \rightarrow \text{iterate}'(v_1 | e_3)]](r'') & \text{if } I[[e_1]](r') = \{x_1, \ldots, x_n\}.
\end{cases}
$$

The semantics of a variable expression (i) is the value assigned to the variable. A let expression (ii) results in the value of the sub-expression $e_2$. Free occurrences of the variable $v$ in $e_2$ are bound to the value of the expression $e_1$. An operation expression (iv) is interpreted by the function associated with the operation. Each argument expression is evaluated separately. The state $\sigma$ is passed to operations whose interpretation depends on the system state. These include, for example, attribute and navigation operations as defined in sub clause A.4.4.

The computation of side-effect free operations can often be described with OCL expressions. We can extend the definition to allow object operations whose effects are defined in terms of OCL expressions. The semantics of a side-effect free operation can then be given by the semantics of the OCL expression associated with the operation. Recall that object operations in OP$_c$ are declared in a model specification. Let oclexp : OP$_c$ $\rightarrow$ Expr be a partial function mapping object operations to OCL expressions. We define the semantics of an operation with an associated OCL expression as $I[[\omega(p_1 : e_1, \ldots, p_n : e_n)](r) = I[[\text{oclexp}(\omega)](r')]$ where $p_1, \ldots, p_n$ are parameter names, and $r' = (\sigma, \beta')$ denotes an environment with a modified variable assignment defined as

$$
\beta' := \beta/p_1/I[[e_1]](r), \ldots, p_n/I[[e_n]](r).
$$

Argument expressions are evaluated and assigned to parameters that bind free occurrences of $p_1, \ldots, p_n$ in the expression oclexp($\omega$). For a well-defined semantics, we need to make sure that there is no infinite recursion resulting from an expansion of the operation call. A strict solution that can be statically checked is to forbid any occurrences of $\omega$ in oclexp($\omega$). However, allowing recursive operation calls considerably adds to the expressiveness of OCL. We therefore allow recursive invocations as long as the recursion is finite. Unfortunately, this property is generally undecidable.

The result of an if-expression (v) is given by the then-part if the condition is true. If the condition is false, the else-part is the result of the expression. A null or invalid condition makes the whole expression invalid. Note that when an expression in one of the alternative branches is null or invalid, the whole expression may still have a well-defined result. For example, the result of the following expression is 1.

$$
\text{if true then } 1 \text{ else } 1 \text{ div } 0 \text{ endif}
$$
The result of a cast expression (vi) using asType is the value of the expression, if the value lies within the domain of the specified target type, otherwise it is invalid. A type test expression with isTypeOf is true if the expression value lies exactly within the domain of the specified target type without considering subtypes. An isKindOf type test expression is true if the expression value lies within the domain of the specified target type or one of its subtypes. Note that these type cast and test expressions also work with null or invalid values since every value – including a null or invalid one – has a well-defined type.

An iterate expression (vii) loops over the elements of a collection and allows the application of a function to each collection element. The function results are successively combined into a value that serves as the result of the whole iterate expression. This kind of evaluation is also known in functional style programming languages as fold operation (see, e.g., [Tho99]).

In Definition A.30, the semantics of iterate expressions is given by a recursive evaluation scheme. Information is passed between different levels of recursion by modifying the variable assignment appropriately in each step. The interpretation of iterate starts with the initialization of the accumulator variable. The recursive evaluation following thereafter uses a simplified version of iterate, namely an expression iterate where the initialization of the accumulator variable is left out, since this sub-expression needs to be evaluated only once. If the source collection is not empty, (1) an element from the collection is bound to the iteration variable, (2) the argument expression is evaluated, and (3) the result is bound to the accumulator variable. These steps are all part of the definition of the variable assignment \( \beta \). The recursion terminates when there are no more elements in the collection to iterate over. The constructor operations mkSequence, mkBag, and mkSet are in \( \Omega_M \) and provide the abstract syntax for collection literals like \( \text{Set} \{1, 2\} \) in concrete OCL syntax.

The result of an iterate expression applied to a set or bag is deterministic only if the inner expression is both commutative and associative.

### A.5.1.3 Derived Expressions Based on Iterate

A number of important OCL constructs such as \( \text{exists}, \text{forAll}, \text{select}, \text{reject}, \text{collect}, \) and \( \text{isUnique} \) are defined in terms of iterate expressions. The following schema shows how these expressions can be translated to equivalent iterate expressions. A similar translation can be found in [Cla99].

\[
I[[ e_1 \rightarrow \text{exists}(v_1 \mid e_3)]](r) = I[[ e_1 \rightarrow \text{iterate}(v_1; v_2 = \text{false} \mid v_2 \text{ or } e_3) ]] (r)
\]

\[
I[[ e_1 \rightarrow \text{forAll}(v_1 \mid e_3) ]] (r) = I[[ e_1 \rightarrow \text{iterate}(v_1; v_2 = \text{true} \mid v_2 \text{ and } e_3) ]] (r)
\]

\[
I[[ e_1 \rightarrow \text{select}(v_1 \mid e_3) ]] (r) =
I[[ e_1 \rightarrow \text{iterate}(v_1; v_2 = e_1 \mid 
\text{if } e_3 \text{ then } v_2 \text{ else } v_2 \rightarrow \text{excluding}(v_1) \text{ endif}) ]] (r)
\]

\[
I[[ e_1 \rightarrow \text{reject}(v_1 \mid e_3) ]] (r) =
I[[ e_1 \rightarrow \text{iterate}(v_1; v_2 = e_1 \mid 
\text{if } e_3 \text{ then } v_2 \rightarrow \text{excluding}(v_1) \text{ else } v_2 \text{ endif}) ]] (r)
\]

\[
I[[ e_1 \rightarrow \text{collect}(v_1 \mid e_3) ]] (r) =
I[[ e_1 \rightarrow \text{iterate}(v_1; v_2 = \text{mkBag}_{\text{type-of-e}_3}() \mid v_2 \rightarrow \text{including}(e_3)) ]] (r)
\]

\[
I[[ e_1 \rightarrow \text{isUnique}(v_1 \mid e_3) ]] (r) =
I[[ e_1 \rightarrow \text{iterate}(v_1; v_2 = \text{true} \mid v_2 \text{ and } e_1 \rightarrow \text{count}(v_1) = 1) ]] (r)
\]
A.5.1.4 Expression Context

An OCL expression is always written in some syntactical context. Since the primary purpose of OCL is the specification of constraints on a UML model, it is obvious that the model itself provides the most general kind of context. In our approach, the signature $\Sigma_M$ contains types (e.g., object types) and operations (e.g., attribute operations) that are “imported” from a model, thus providing a context for building expressions that depend on the elements of a specific model.

On a much smaller scale, there is also a notion of context in OCL that simply introduces variable declarations. This notion is closely related to the syntax for constraints written in OCL. A context clause declares variables in invariants, and parameters in pre- and postconditions.

A context of an invariant is a declaration of variables. The variable declaration may be implicit or explicit. In the implicit form, the context is written as

```
context $C$ inv:
  <expression>
```

In this case, the <expression> may use the variable self of type $C$ as a free variable. In the explicit form, the context is written as

```
context $v_1 : C_1, \ldots, v_n : C_n$ inv:
  <expression>
```

The <expression> may use the variables $v_1, \ldots, v_n$ of types $C_1, \ldots, C_n$ as free variables.

A context of a pre-/postcondition is a declaration of variables. In this case, the context is written as

```
context $C :: op(p_1 : T_1, \ldots, p_n : T_n) : T$
  pre: $P$
  post: $Q$
```

This means that the variable self (of type $C$) and the parameters $p_1, \ldots, p_n$ may be used as free variables in the precondition $P$ and the postcondition $Q$. Additionally, the postcondition may use result (of type $T$) as a free variable. The details are explained in sub clause A.5.2.

A.5.1.5 Invariants

An invariant is an expression with boolean result type and a set of (explicitly or implicitly declared) free variables

$v_1 : C_1, \ldots, v_n : C_n$ where $C_1, \ldots, C_n$ are classifier types. An invariant

```
context $v_1 : C_1, \ldots, v_n : C_n$ inv:
  <expression>
```

is equivalent to the following expression without free variables that must be valid in all system states.

```
$C_1$.allInstances->forAll($v_1 : C_1 |$
  ...
  $C_n$.allInstances->forAll($v_n : C_n |$
    <expression>
  )
)
```

A system state is called valid with respect to an invariant if the invariant evaluates to true. Invariants with null or invalid result invalidate a system state.
A.5.2 Pre- and Postconditions

The definition of expressions in the previous sub clause is sufficient for invariants and queries where we have to consider only single system states. For pre- and postconditions, there are additional language constructs in OCL that enable references to the system state before the execution of an operation and to the system state that results from the operation execution. The general syntax of an operation specification with pre- and postconditions is defined as

\[
\text{context } C :: \text{op}(p_1 : T_1, \ldots, p_n : T_n)
\]

\[
\text{pre: } P
\]

\[
\text{post: } Q
\]

First, the context is determined by giving the signature of the operation for which pre- and postconditions are to be specified. The operation \( \text{op} \) which is defined as part of the classifier \( C \) has a set of typed parameters \( \text{PARAMS}_{\text{op}} = \{p_1, \ldots, p_n\} \). The UML model providing the definition of an operation signature also specifies the direction kind of each parameter. We use a function \( \text{kind} : \text{PARAMS}_{\text{op}} \rightarrow \{\text{in, out, inout, return}\} \) to map each parameter to one of these kinds. Although UML makes no restriction on the number of return parameters, there is usually only at most one return parameter considered in OCL, which is referred to by the keyword \( \text{result} \) in a postcondition. In this case, the signature is also written as \( C :: \text{op}(p_1 : T_1, \ldots, p_{n-1} : T_{n-1}) : T \) with \( T \) being the type of the \( \text{result} \) parameter.

The precondition of the operation is given by an expression \( P \), and the postcondition is specified by an expression \( Q \). \( P \) and \( Q \) must have a boolean result type. If the precondition holds, the contract of the operation guarantees that the postcondition is satisfied after completion of \( \text{op} \). Pre- and postconditions form a pair. A condition defaults to true if it is not explicitly specified.

A.5.2.1 Example

Before we give a formal definition of operation specifications with pre- and postconditions, we demonstrate the fundamental concepts by means of an example. Figure A.1 shows a class diagram with two classes \( A \) and \( B \) that are related to each other by an association \( R \). Class \( A \) has an operation \( \text{op}() \) but no attributes. Class \( B \) has an attribute \( c \) and no operations. The implicit role names \( a \) and \( b \) at the link ends allow navigation in OCL expressions from a \( B \) object to the associated \( A \) object and vice versa.

![Figure A.1 - Example class diagram](image)

Figure A.2 shows an example for two consecutive states of a system corresponding to the given class model. The object diagrams show instances of classes \( A \) and \( B \) and links of the association \( R \). The left object diagram shows the state before the execution of an operation, whereas the right diagram shows the state after the operation has been executed. The effect of the operation can be described by the following changes in the post-state: (1) the value of the attribute \( c \) in object \( b_1 \) has been incremented by one, (2) a new object \( b_2 \) has been created, (3) the link between \( a \) and \( b_1 \) has been removed, and (4) a new link between \( a \) and \( b_2 \) has been established.
For the following discussion, consider the OCL expression `a.b.c` where `a` is a variable denoting the object `a`. The expression navigates to the associated object of class `B` and results in the value of the attribute `c`. Therefore, the expression evaluates to 1 in the pre-state shown in Figure A.2(a). As an example of how the OCL modifier `@pre` may be used in a postcondition to refer to properties of the previous state, we now look at some variations of the expression `a.b.c` that may appear as part of a postcondition. For each case, the result is given and explained.

- `a.b.c = 0`
  Because the expression is completely evaluated in the post-state, the navigation from `a` leads to the `b2` object. The value of the attribute `c` of `b2` is 0 in Figure A.2(b).

- `a.b@pre.c = 2`
  This expression refers to both the pre- and the post-state. The previous value of `a.b` is a reference to object `b1`. However, since the `@pre` modifier only applies to the expression `a.b`, the following reference to the attribute `c` is evaluated in the post-state of `b1`, even though `b1` is not connected anymore to `a`. Therefore, the result is 2.

- `a.b@pre.c@pre = 1`
  In this case, the value of the attribute `c` of object `b1` is taken from the pre-state. This expression is semantically equivalent to the expression `a.b.c` in a precondition.

- `a.b.c@pre = ⊥`
  The expression `a.b` evaluated in the post-state yields a reference to object `b2` which is now connected to `a`. Since `b2` has just been created by the operation, there is no previous state of `b2`. Hence, a reference to the previous value of attribute `c` is invalid.

Note that the `@pre` modifier may only be applied to operations not to arbitrary expressions. An expression such as `(a.b)@pre` is syntactically illegal.

OCL provides the standard operation `oclIsNew` for checking whether an object has been created during the execution of an operation. This operation may only be used in postconditions. For our example, the following conditions indicate that the object `b2` has just been created in the post-state and `b1` already existed in the pre-state.
A.5.2.2 Syntax and Semantics of Postconditions

All common OCL expressions can be used in a precondition \( P \). Syntax and semantics of preconditions are defined exactly like those for plain OCL expressions in sub clause A.5.1. Also, all common OCL expressions can be used in a postcondition \( Q \). Additionally, the @pre construct, the special variable \( \text{result} \), and the operation \( \text{oclIsNew} \) may appear in a postcondition. In the following, we extend Definition A.29 for the syntax of OCL expressions to provide these additional features.

Definition A.31 (Syntax of Expressions In Postconditions)

Let \( \text{op} \) be an operation with a set of parameters \( \text{PARAMS}_{\text{op}} \). The set of parameters includes at most one parameter of kind “return.” The basic set of expressions in postconditions is defined by repeating Definition A.29 while substituting all occurrences of \( \text{Expr}_t \) with \( \text{Post-Expr}_t \). Furthermore, we define that:

- Each non-return parameter \( p \in \text{PARAMS}_{\text{op}} \) with a declared type \( t \) is available as variable: \( p \in \text{Var}_t \).
- If \( \text{PARAMS}_{\text{op}} \) contains a parameter of kind “return” and type \( t \) then \( \text{result} \) is a variable: \( \text{result} \in \text{Var}_t \).
- The operation \( \text{oclIsNew} : c \rightarrow \text{Boolean} \) is in \( \Omega_M \) for all object types \( c \in T_M \).

The syntax of expressions in postconditions is extended by the following rule.

vii. If \( \omega : t_1 \times \ldots \times t_n \rightarrow t \in \Omega_M \) and \( e_i \in \text{Post-Expr}_t \) for all \( i = 1, \ldots, n \) then

\[
\omega_{\@pre}(e_1, \ldots, e_n) \in \text{Post-Expr}_t.
\]

All general OCL expressions may be used in a postcondition. Moreover, the basic rules for recursively constructing expressions do also apply. Operation parameters are added to the set of variables. For operations with a return type, the variable \( \text{result} \) refers to the operation result. The set of operations is extended by \( \text{oclIsNew} \) which is defined for all object types. Operations \( \omega_{\@pre} \) are added for allowing references to the previous state (vii). The rule says that the \( \@pre \) modifier may be applied to all operations, although, in general, not all operations do actually depend on a system state (for example, operations on data types). The result of these operations will be the same in all states. Operations that do depend on a system state are, e.g., attribute access and navigation operations.

For a definition of the semantics of postconditions, we will refer to environments describing the previous state and the state resulting from executing the operation. An environment \( \pi = (\sigma, \beta) \) is a pair consisting of a system state \( \sigma \) and a variable assignment \( \beta \) (see sub clause A.5.1.2). The necessity of including variable assignments into environments will be discussed shortly. We call an environment \( \pi_{\text{pre}} = (\sigma_{\text{pre}}, \beta_{\text{pre}}) \) describing a system state and variable assignments before the execution of an operation a pre-environment. Likewise, an environment \( \pi_{\text{post}} = (\sigma_{\text{post}}, \beta_{\text{post}}) \) after the completion of an operation is called a post-environment.

Definition A.32 (Semantics of Postcondition Expressions)

Let \( \text{Env} \) be the set of environments. The semantics of an expression \( e \in \text{Post-Expr} \) is a function \( I[[ e ]] : \text{Env} \times \text{Env} \rightarrow I(t) \). The semantics of the basic set of expressions in postconditions is defined by repeating Definition A.30 while substituting all occurrences of \( \text{Expr} \), with \( \text{Post-Expr} \). References to \( I[[ e ]](r) \) are replaced by \( I[[ e ]](r_{\text{pre}}, r_{\text{post}}) \) to include the pre-environment. Occurrences of \( r \) are changed to \( r_{\text{post}} \) which is the default environment in a postcondition.

- For all \( p \in \text{PARAMS}_{\text{op}} \), \( I[[ p ]](r_{\text{pre}}, r_{\text{post}}) = \beta_{\text{post}}(p) \).

Input parameters may not be modified by an operation:
kind\((p)\) = in \implies \beta_{\text{pre}}(p) = \beta_{\text{post}}(p).

• Output parameters are null on entry:
  \(\text{kind}(p) = \text{out} \implies \beta_{\text{pre}}(p) = \epsilon\).

• \(I([[\text{result}]])(r_{\text{pre}}, r_{\text{post}}) = \beta_{\text{post}}(\text{result}).\)

vii. \(I([[\text{oclIsNew}]])(r_{\text{pre}}, r_{\text{post}})(c) =
\begin{cases}
  \text{true} & \text{if } c \not\in \sigma_{\text{pre}}(c) \text{ and } c \in \sigma_{\text{post}}(c), \\
  \text{false} & \text{otherwise.}
\end{cases}\)

Standard expressions are evaluated as defined in Definition A.30 with the post-environment determining the context of evaluation. Input parameters do not change during the execution of the operation. Therefore, their values are equal in the pre- and post-environment. The value of the \(\text{result}\) variable is determined by the variable assignment of the post-environment. The \(\text{oclIsNew}\) operation yields true if an object did not exist in the previous system state. Operations referring to the previous state are evaluated in context of the pre-environment (vii). Note that the operation arguments may still be evaluated in the post-environment. Therefore, in a nested expression, the environment only applies to the current operation, whereas deeper nested operations may evaluate in a different environment.

With these preparations, the semantics of an operation specification with pre- and postconditions can be precisely defined as follows. We say that a precondition \(P\) \emph{satisfies} a pre-environment \(r_{\text{pre}}\) – written as \(r_{\text{pre}} \models P\) – if the expression \(P\) evaluates to true according to Definition A.30. Similarly, a postcondition \(Q\) satisfies a pair of pre- and post-environments, if the expression \(Q\) evaluates to true according to Definition A.32:

\[
  r_{\text{pre}} \models P \quad \text{iff} \quad I([[P]])(r_{\text{pre}}) = \text{true}
\]

\[
  (r_{\text{pre}}, r_{\text{post}}) \models Q \quad \text{iff} \quad I([[Q]])(r_{\text{pre}}, r_{\text{post}}) = \text{true}
\]

\textbf{Definition A.33 (Semantics of Operation Specifications)}

The semantics of an operation specification is a set \(R \subseteq \text{Env} \times \text{Env}\) defined as

\[
  [[\text{context } C :: \text{op}(p_1 : T_1, \ldots, p_n : T_n) \text{ pre: } P \text{ post: } Q]] = R
\]

where \(R\) is the set of all pre- and post-environment pairs such that the pre-environment \(r_{\text{pre}}\) satisfies the precondition \(P\) and the pair of both environments satisfies the postcondition \(Q\):

\[
  R = \{ (r_{\text{pre}}, r_{\text{post}}) | r_{\text{pre}} \models P \land (r_{\text{pre}}, r_{\text{post}}) \models Q \}
\]

The satisfaction relation for \(Q\) is defined in terms of both environments since the postcondition may contain references to the previous state. The set \(R\) defines all legal transitions between two states corresponding to the effect of an operation. It therefore provides a framework for a correct implementation.

\textbf{Definition A.34 (Satisfaction of Operation Specifications)}

An operation specification with pre- and postconditions is satisfied by a program \(S\) in the sense of total correctness if the computation of \(S\) is a total function \(f_S : \text{dom}(R) \to \text{im}(R)\) and \(\text{graph}(f_S) \subseteq R\).

In other words, the program \(S\) accepts each environment satisfying the precondition as input and produces an environment that satisfies the postcondition. The definition of \(R\) allows us to make some statements about the specification. In general, a reasonable specification implies a non-empty set \(R\) allowing one or more different implementations of the operation.

© ISO/IEC 2012 - All rights reserved 227
$R = \emptyset$, then there is obviously no implementation possible. We distinguish two cases: (1) no environment satisfying the precondition exists, or (2) there are environments making the precondition true, but no environments do satisfy the postcondition. Both cases indicate that the specification is inconsistent with the model. Either the constraint or the model providing the context should be changed. A more restrictive definition might even prohibit the second case.

C.2 Use Of Specification - Terms, Conditions & Notices

The material in this document details an Object Management Group specification in accordance with the terms, conditions and notices set forth below. This document does not represent a commitment to implement any portion of this International Standard in any company’s products. The information contained in this document is subject to change without notice.

C.3 Licenses

The companies listed above have granted to the Object Management Group, Inc. (OMG) a nonexclusive, royalty-free, paid up, worldwide license to copy and distribute this document and to modify this document and distribute copies of the modified version. Each of the copyright holders listed above has agreed that no person shall be deemed to have infringed the copyright in the included material of any such copyright holder by reason of having used the specification set forth herein or having conformed any computer software to the specification.

Subject to all of the terms and conditions below, the owners of the copyright in this International Standard hereby grant you a fully-paid up, non-exclusive, nontransferable, perpetual, worldwide license (without the right to sublicense), to use this International Standard to create and distribute software and special purpose specifications that are based upon this International Standard, and to use, copy, and distribute this International Standard as provided under the Copyright Act; provided that: (1) both the copyright notice identified above and this permission notice appear on any copies of this International Standard; (2) the use of the specifications is for informational purposes and will not be copied or posted on any network computer or broadcast in any media and will not be otherwise resold or transferred for commercial purposes; and (3) no modifications are made to this International Standard. This limited permission automatically terminates without notice if you breach any of these terms or conditions. Upon termination, you will destroy immediately any copies of the specifications in your possession or control.
C.4 Patents

The attention of adopters is directed to the possibility that compliance with or adoption of OMG specifications may require use of an invention covered by patent rights. OMG shall not be responsible for identifying patents for which a license may be required by any OMG specification, or for conducting legal inquiries into the legal validity or scope of those patents that are brought to its attention. OMG specifications are prospective and advisory only. Prospective users are responsible for protecting themselves against liability for infringement of patents.

C.5 General Use Restrictions

Any unauthorized use of this International Standard may violate copyright laws, trademark laws, and communications regulations and statutes. This document contains information which is protected by copyright. All Rights Reserved. No part of this work covered by copyright herein may be reproduced or used in any form or by any means--graphic, electronic, or mechanical, including photocopying, recording, taping, or information storage and retrieval systems--without permission of the copyright owner.

C.6 Disclaimer Of Warranty

WHILE THIS PUBLICATION IS BELIEVED TO BE ACCURATE, IT IS PROVIDED "AS IS" AND MAY CONTAIN ERRORS OR MISPRINTS. THE OBJECT MANAGEMENT GROUP AND THE COMPANIES LISTED ABOVE MAKE NO WARRANTY OF ANY KIND, EXPRESS OR IMPLIED, WITH REGARD TO THIS PUBLICATION, INCLUDING BUT NOT LIMITED TO ANY WARRANTY OF TITLE OR OWNERSHIP, IMPLIED WARRANTY OF MERCHANTABILITY OR WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE OR USE.

IN NO EVENT SHALL THE OBJECT MANAGEMENT GROUP OR ANY OF THE COMPANIES LISTED ABOVE BE LIABLE FOR ERRORS CONTAINED HEREIN OR FOR DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL, RELIANCE OR COVER DAMAGES, INCLUDING LOSS OF PROFITS, REVENUE, DATA OR USE, INCURRED BY ANY USER OR ANY THIRD PARTY IN CONNECTION WITH THE FURNISHING, PERFORMANCE, OR USE OF THIS MATERIAL, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

The entire risk as to the quality and performance of software developed using this International Standard is borne by you. This disclaimer of warranty constitutes an essential part of the license granted to you to use this International Standard.

C.7 Restricted Rights Legend

Use, duplication or disclosure by the U.S. Government is subject to the restrictions set forth in subparagraph (c) (1) (ii) of The Rights in Technical Data and Computer Software Clause at DFARS 252.227-7013 or in subparagraph (c)(1) and (2) of the Commercial Computer Software - Restricted Rights clauses at 48 C.F.R. 52.227-19 or as specified in 48 C.F.R. 227-7202-2 of the DoD F.A.R. Supplement and its successors, or as specified in 48 C.F.R. 12.212 of the Federal Acquisition Regulations and its successors, as applicable. The specification copyright owners are as indicated above and may be contacted through the Object Management Group, 140 Kendrick Street, Needham, MA 02494, U.S.A.

C.8 Trademarks

MDA®, Model Driven Architecture®, UML®, UML Cube logo®, OMG Logo®, CORBA® and XMI® are registered trademarks of the Object Management Group, Inc., and Object Management Group™, OMG™, Unified Modeling Language™, Model Driven Architecture Logo™, Model Driven Architecture Diagram™, CORBA logos™, XMI Logo™,
CWM™, CWM Logo™, IIOP™, MOF™ and OMG Interface Definition Language (IDL)™, and Systems Modeling Language (SysML™) are trademarks of the Object Management Group. All other products or company names mentioned are used for identification purposes only, and may be trademarks of their respective owners.

C.9 Compliance

The copyright holders listed above acknowledge that the Object Management Group (acting itself or through its designees) is and shall at all times be the sole entity that may authorize developers, suppliers and sellers of computer software to use certification marks, trademarks or other special designations to indicate compliance with these materials.

Software developed under the terms of this license may claim compliance or conformance with this International Standard if and only if the software compliance is of a nature fully matching the applicable compliance points as stated in the specification. Software developed only partially matching the applicable compliance points may claim only that the software was based on this International Standard, but may not claim compliance or conformance with this International Standard. In the event that testing suites are implemented or approved by Object Management Group, Inc., software developed using this International Standard may claim compliance or conformance with the specification only if the software satisfactorily completes the testing suites.
